ENGINEERING NEWS-RECORD

A WEEKLY JOURNAL
DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN
Editor

CHARLES WHITING BAKER
Consulting Editor

Volume 82 — NEW YORK, THURSDAY, JANUARY 2, 1919 — Number 1

"Engineering News-Record" is a consolidation of "Engineering News" and "Engineering Record."

"Engineering News" was founded in 1874 by George H. Frost, as the "Engineer and Surveyor," which title subsequently became the "Engineer, Architect and Surveyor," then "Engineering News and American Railway Journal" and, finally, "Engineering News," under the successive editorships of D. McN. Stauffer, Arthur M. Wellington and Charles Whiting Baker.

"Engineering Record" was established in 1877 by Henry C. Meyer as the "Plumber and Sanitary Engineer. The name was subsequently changed to the "Sanitary Engineer," "Engineering and Building Record" and, finally, to "Engineering Record." During his ownership of the paper, Mr. Meyer was directly responsible for the editorial policy. John M. Goodell became editor in 1902, and was succeeded by E. J. Mehren.

The staff of "Engineering News-Record" is composed of

E. J. Mehren, *Editor*
Charles Whiting Baker, *Consulting Editor*
M. N. Baker — J. P. J. Williams
F. E. Schmitt — Morgan Cilley
F. C. Wight — F. T. Townsend
H. H. French
Chicago: W. W. DeBerard, E. E. R. Tratman, C. S. Hill
San Francisco: N. A. Bowers
On Leave of Absence:
R. K. Tomlin, Jr. *Captain, Engineers, A.E.F., France*
Harry Barker, *Captain, Engineers, on special duty at New York*

In Honor of American Shipbuilders

IT IS an honor and a privilege to dedicate this first of the year number to the American shipbuilders, and particularly to those among them who are our own brethren—the civil engineers and contractors who threw themselves unreservedly into the work, and were no small factor in its marvelous success and development. Fittingly, the issue opens with a message to these professional brethren from Edward N. Hurley, chairman of the United States Shipping Board. With emphasis and repetition he pays tribute to what they did. What is more, he promises that the industry they helped to build under stress of war will be permanent. That his vision may not be belied, he pleads that America may become "ship-minded," that, thinking internationally, we may acquire a fostering pride that shall install shipping as a permanent American industry. If we may speak for American civil engineers and contractors in reply to Mr. Hurley, we would say that they will be no less loyal in trying to perpetuate the industry than they were in building it. The keynote for a permanent industry is efficiency, efficiency in ship building, efficiency in ship operation. Both are the work of the engineer, for ship operation involves not merely the navigation of the ship and the handling of the crew at sea but the creation and operation of terminals that will load and discharge cargo rapidly and economically. There must also be favorable external conditions—which include what Mr. Hurley terms "ship-mindedness." Here, too, the engineer and the contractor will back Mr. Hurley in his efforts to give us a permanent merchant marine.

Carrying Abroad America's Engineering Message

REALIZING the value of the international exchange of ideas on things engineering, the McGraw-Hill Company on March 1 will begin publication of a magazine dedicated to that purpose. While eventually it is expected to appear in editions in several languages, the original issue will be in Spanish, under the name, *"La Ingenieria Internacional."* It is aimed to serve Latin America and Spain. The purpose of the new magazine, which has been under consideration for some years, is to afford a medium for the presentation of those developments in American engineering which may be of value to engineers, contractors and manufacturers in other lands. At the same time, following the practice of the present McGraw-Hill publications, a far-flung editorial organization will be developed, so that there will be drawn into the paper the best of engineering practice in Latin America, Spain and other Spanish-speaking countries. Aside from this function, the new magazine will be an important developer of international good-will, and at the same time a medium by which American manufacturers engaging in export trades can carry their message to prospective buyers in foreign lands. It may be a cause of surprise that the McGraw-Hill Company, whose specialized papers circulate so widely overseas, should establish a magazine to serve the foreign field. The reason, however, is not hard to find. The present highly specialized papers appeal only to those who are situated where engineering enterprise has made such progress that there is room for the specialist and need for the last refinement in equipment and design. But everywhere, the world over, are territories newly developing, where the engineer, the contractor and the manufacturer must each turn his hand to many lines. It is to serve the general practitioner so situated that the new magazine, and its later companions in other languages, will be started.

Will Prices and Wages Drop?

ON THE theory that there will be a marked drop in prices and wages, owners are holding in abeyance their construction projects. Is their expectation correct? Prices and wages, in the last analysis, are determined by the laws of supply and demand. They were forced to high levels by the war, since the supply of materials and labor was very short and the demand very great. The volume of goods which can be consumed, in the present state of the world's warehouses, may easily exceed the war demand, but the urgency of the war demand being absent, the conclusion seems sound that price and wage levels will recede. The puzzling question is as to the extent of the recession. In all likelihood the drop will be small, for, as one shrewd observer put it, "the shelves of the world are bare." That applies as well to public works, railroad improvements and private buildings as it does to manufactured articles. Highways have been neglected, cities without number are short of housing (and therefore of water-supply, sewerage, paving, fire protection, etc.), office building space is at a premium everywhere. Price and wage levels will probably go off, but, with a still abnormal demand and a lessened man-power, not only will the pre-war levels not be reached, but the price recession within a year will not be large. Just what the recession may be no one is willing to predict. Some place 15 per cent. as a maximum, others 25 per cent. But there is quite general agreement that all of the substantial lowering will come between now and June. It would not be surprising if in some products prices would again rise after the full peace demand is felt. What is lacking in war's insistence will be made up by the optimism of a renascent world.

Are We Wanted in France and Belgium?

EVERY day the question is asked of *Engineering News-Record*, "Are American engineers and contractors wanted in France and Belgium?" This journal has been at pains to learn the answer, and the answer at the present minute is, "No." France and Belgium, so far as their agencies in this country are informed, feel confident that their own engineers and contractors can satisfactorily handle the situation. Moreover, the materials will be largely of European origin. Only for construction machinery do the Belgians and the French seem to be turning to this country. Such at least is the situation for the present. What change will be brought about when the question of credits for restoration is raised remains to be seen. If they are granted by the United States Government, there will be the usual string, for the credit will be available in this country. What seems more likely than the granting of extensive Government credits is that strong financial groups here will undertake the financing of projects abroad, and will inevitably pick out large contracting organizations to do the work. When that time comes the personnel will likely be recruited in part here and in part from our men released abroad from military service. For the present, however, we must await the decision of the French and Belgian authorities upon the method of financing the work of restoration.

Unparalleled Municipal Opportunities

NINETEEN-NINETEEN offers unparalleled opportunities to every city, town and village in the land. Hosts of soldiers, sailors and war workers will be eager for employment, contractors and supply men will be turning from military to civil contracts, engineers and other technically trained men will stand ready to plan and direct construction, all after years during which municipal improvements have been at a standstill. At such a juncture great service may be rendered, by the undertaking of extensive construction, to those who have devoted themselves to the cause of democracy at home and abroad, while at the same time industry will be stabilized, general prosperity promoted and our municipalities provided with long-delayed and much-needed improvements.

To fulfill these multiple opportunities for service requires extensive and careful planning, both physical and financial. Some cities have already done such planning, or have it well under way. Others have scarcely begun. There is no time to lose. The construction season will soon be upon us. Men needing work, and highly deserving it, will be seeking employment in ever-increasing numbers, unless every city and village does its part.

Municipal work for 1919 should be planned with a view to starting first on jobs which can be got under way early in the year, and which can be adjusted readily to the labor supply, and perhaps to the materials supply as well.

No city should look upon finding employment for the demobilized as mere stop-gap work. There will be more need than ever in this year and succeeding years to have every undertaking fit into a carefully devised municipal program. As proof of this, let any city engineer, mayor, commissioner or councilman take pencil and paper and set down needed improvements and their approximate costs. The list will soon reach such a length and total as will exceed the financial ability of the municipality for years to come. This means that work for 1919 and succeeding years must be selected with regard to its relative value and urgency.

Where city-planning commissions with vision exist, municipal programs will have been formed before this. Where they exist but lack vision, it behooves them to open their eyes and their minds and point the way. Cities without planning boards might well create them, if state legislation permits, or seek statutory authority with the opening of their legislatures, where it is now lacking. But no city or village should wait for the legislature to authorize a planning commission. Coöperation among existing officials and the mere saying the word "plan" to the city engineer may be immediately productive of results.

Where there's a will there's a way. The opportunities for municipal improvements, combined with unparalleled service, are many and great. The war has been won, but the world and this country will not have been made "safe for democracy" if suitable work at adequate pay is not provided, both now and in the future, for every soldier, sailor and toiler who helped win the war.

The world expects every American municipality to do its duty.

A Year of Apprenticeship in Shipbuilding

THERE is satisfaction of a high type in the marvelous achievement of the nation during the year—multiplying its shipbuilding power to the degree that ten times as much was constructed as in any previous year. But it is no less satisfying to find that while building we have been learning. The year has been one of apprenticeship in the shipbuilding art.

During the hard winter that ushered in the new year of 1918 a new system for producing ships was just being put to trial. The inadequacy of the old methods and equipment furnished the motive. Yet before the new fabrication system had been made a reality came a more amazing development in the sudden rise of the old shipbuilding art to a wholly new level of achievement. And it is through the power of the revivified old art, without essential aid from the fabricating yards, that the country was able to set new standards in ship construction.

Much has been said in derogation of the speed-ship work; the results have been called stagey, all prepared for. But this very point gave the clew, it soon appeared: If a good performance resulted from thorough preparation, why should not preparation precede every piece of work? The advance was made right there. Each case, "Tuckahoe" or "Crawl Keys," reinforced the preceding ones in bringing this point to the fore.

The spirit of better management was grasped quite broadly. Yard after yard, discovering that labor could be used more efficiently, and equipment more intensively, by management, set about providing for steady flow of work, preparing all tasks, guarding against mutual interference of men and of material. Yards were expanded and rebuilt, to permit of doing this. When, in the midst of this activity a shop-trained manufacturer stepped into the shipbuilding field to build patrol boats, it turned out that what he had learned in factory work and carried over into his yard was already being applied by shipbuilders.

While the old-line yards moved forward thus, it is regrettable that ship fabrication lacked time to exhibit its full power of production. It is just as regrettable that the authorities have maintained silence on what results are being achieved by this iconoclastic method. For our coming development we need to have the guiding marks set. It is gratifying, therefore, that the review which we have been able to compile of results obtained in the use of the fabrication system gives grounds for a certain amount of optimism concerning its utility.

Specialization problems lead in the shipbuilding field today. There is specialization in labor and in equipment, while there is coming yard specialization, still in its earliest stages, but clearly indicated by the yards that are planned for definite sizes of ships and the yards that are pure assembly plants, with shop processes transferred to outside enterprises as far as possible.

In the future, specialization may develop further. Mr. Hurley's strong words on the unpredictable possibilities of our renascent maritime business mean too much to pass quickly out of mind. He opens a prospect into years that may bring many new tasks. But whether the key to their solution be increased efficiency, or specialization, we are the better prepared for them by the apprenticeship of the months just past. And we are the more amply equipped by being able to center on those tasks the fresh energy of the new working forces that have been gathered into the yards.

Light Aggregate For Structural Concrete

CONCRETE is essentially an artificial stone, and it approximates to the natural material even in weight. Though largely used as a structural material in frameworks where weight is a detriment, the original nature of concrete has so thoroughly controlled its uses that little effort has been made, until the past year, to effect a desirable saving in weight with no loss in strength. In developing a light but strong aggregate, then, the concrete-ship pioneers have now opened new possibilities for structural concrete, whether or not the concrete ship is more than a war-time expedient.

The invention of a light aggregate was born of necessity. Early in their studies the engineers of the Concrete Ship Section of the Emergency Fleet Corporation found that to compete in carrying capacity, and therefore in operating cost, with the steel ship, the concrete ship could not possibly use the standard 150-lb. concrete which had come to be accepted as inevitable in structural work. Experiments were made with many substances, both artificial and natural, before approval was fixed on a burnt shale-clay resembling in appearance certain volcanic tufas of the Pacific Coast.

Full information regarding the manufacture and properties of this material will soon be made public. At present it is sufficient to say that it fully satisfies the requirements of the Concrete Ship Section, that one large ship has been built of it, and a contract has been let for 10,000 tons to a cement company which is producing the material in one of its rotary kilns. Roughly speaking, the aggregate, crushed to ¼- and ½-in. size, makes a 1 : 2 concrete weighing about 100 lb. per cubic foot and breaking in compression at 4000 lb. in 28 days.

Assuming that more exhaustive tests will confirm these figures, the aggregate is a most important development in concrete construction. Dead load is a serious factor in reinforced-concrete design. No small part of every concrete member goes to support the member itself, and the accumulation of these dead loads as the foundation is approached further increases the required size of every member. If this dead load can be reduced 40 or 50 per cent., not only with no loss but actually with a gain in strength, the field of concrete in structural work has been widely extended.

As in all engineering problems, this one hinges on relative cost. The probability of a wider use of a structurally effective light aggregate depends on how cheaply it can be put down at the job. On this score there are not yet sufficient data to base predictions. It can be said, however, that the basic clay from which it is made is widespread, and that the technique of production is not so complicated that it cannot readily be undertaken at any modern kiln. Already aggregates of practically identical properties have been produced in Alabama, New Jersey, Missouri and California. Assuming that production of the aggregate will be undertaken commercially, it becomes a matter of computation for each structure whether a possible increase in cost due to the

special aggregate is balanced by the saving not only in concrete and steel, due to reduced dead weight, but, in building work, in the value of the space gained by the more slender columns of the lower stories. As used in shipwork the light-aggregate concrete is rich and strong, and the aggregate itself is fine. Such concrete is, of course, expensive, but in static structures, except possibly in columns, a leaner concrete with coarser aggregates would be used.

In mass concrete, weight is often a desideratum. Specially heavy aggregates giving concrete weighing up to 190 lb. per cubic foot have been used in dams, with resulting greater efficiency against overturning or shoving action of the retained water. In articulated structures, on the contrary, strength with minimum weight is wanted. It has been the impression for years that the two properties, strength and weight, were more or less proportional in concrete, and that an aggregate which floats, as does this new burnt clay, could not possibly have a strength usable in structures. If these views are to be revised and the new aggregate has such strength as the Government studies so far show it to have, its application is readily obvious to all structural engineers. There will be placed in their hands practically a new material whose economic advantages will need consideration in all projected designs.

What War Has Done for Contracting

THE war has benefited contracting.

A year ago this statement could not have been substantiated. Even now we are too close to events to make a true estimate of their influence. Only mental myopia can, however, blind one to the main fact that the war has given contracting a spirit and a purpose not possessed a year ago. Contracting is a far more definite force in industrial affairs than it was. With the coöperation of organized engineering and organized labor, it can become the power which will recreate a new, stable, construction industry. Only the tenets of an ancient autocracy stand in the way of such coöperation. A democracy of the engineer, the contractor and the workman, dedicated to the common purpose of service to construction, is a goal which war has brought within our vision.

In canvassing the war's accomplishments for contracting, one's thought leaps first to the successful operation in war construction of the cost-plus-sliding-scale-fee contract. A work of greater creative influence has been the development among contractors of a strengthened spirit of coöperation, culminating in the organization of the Associated General Contractors of America. And still there have been other gains.

A year ago the wisdom of the new war-construction contract was being questioned. The lapse of twelve months has furnished the answer. It is this: The cost-plus-sliding-scale-fee contract has operated successfully, and should not be permitted to disappear from public-works practice. It may well be that the details of this contract can profitably be altered, but its principle of assured fair compensation should be maintained inviolate. Government officials who have directed war construction, contractors who have performed this construction, and engineers who have watched the war work are a unit in this opinion. They are supported by the record of a thousand million dollars' worth of work accomplished with remarkable speed and with astonishing harmony between engineers and contractors and workmen.

Organized contracting is, in a very definite way, the outcome of war construction. Do not misread this assertion. The elements for organization existed; war conditions merely vitalized the spirit to organize. Patriotism was one of the influences; business foresight was another; perhaps also shame at being in a position where a gratuity must be accepted instead of a right demanded. The paramount force, however, was the lesson of the power of organization which war wrote for a nation to read.

When the call came to mobilize for war construction organized labor responded, and so did an organized construction materials industry. Contractors responded, but not organized contracting. Contracting had no organization. It is true that its interests were guarded in planning the war work, but the guardians were the engineers of the Federal war-construction bureaus. It was these facts, coming home to the contractors who were called upon for war work, which crystallized the sentiment that has materialized in the Associated General Contractors of America.

Recognition of the doctrine of the partnership of labor in the construction industry is another accomplishment of war. Organized labor had a seat in the councils which determined the policies of war construction. All that followed in improved working conditions was merely an outcome of the original action. Labor has made it plain that these privileges gained will not willingly be abandoned. Nor does sound reasoning advise their abandonment. Construction, like other industries, has reached the stage in its relations with labor where the decision must be made between comradeship or battle. War construction has demonstrated that comradeship is practicable.

War, then, has educated contracting to the possibility of establishing fair-compensation contracts; to the recognition of labor's right to participate in the management of construction, and to the advantages of organization. These are great gains. Let us not overestimate them. The principle of the fair-compensation contract has not become a belief; national organization of the contracting business has barely been begun, and the right of labor to partnership in management has been recognized but not accepted. Obviously, the problems ahead are mighty ones. What of the method of their solution? War has provided the answer here, also.

Organized coöperation of engineer, contractor and workman is the primary essential. If ground gained is not to be given up, this coöperation must be immediate. What stands in the way? Distrust between engineer and contractor; intolerance by both of the claim of labor to the right of a voice in determining the conduct of work. Successful coöperation of all three, impelled by the common purpose of war service, demonstrated how superficial the reason was for distrust and intolerance. It needs only the disposition of organized engineering and organized contracting and organized labor to come together in consultation to expose the shallowness of the reason even in peace-time construction.

American Ships—A Field of Vast Technical Opportunities

A Message to the Engineers and Contractors Who Threw Themselves Unreservedly Into War Production of Ships and Now Ask As to the Future of the Shipbuilding Industry

By Edward N. Hurley
Chairman, United States Shipping Board

IN THE building and manning of our new shipyards in the past twenty months there has been a tendency to overlook the contribution of the technical man.

That contribution has been very great. Only by making generous drafts upon the accumulated technical skill of other American industries has it been possible to produce war transports and food ships in record time.

But our task of organizing and mobilizing a new shipbuilding industry in a matter of months, in the emergency of war, caused the technical factor to be lost sight of for a time. We had to achieve the superhuman. The first appeal was patriotic. Had it not been possible to stir deeply the manual workers of this country, bring them into the shipyards by tens of thousands, and stimulate them to national service, we should never have succeeded. It was necessary to create new viewpoints among craftsmen, inspire them with a willingness to learn new trades, and call upon them for unusual energy and production. Had we not begun our task at this end we should never have accomplished what was necessary under the circumstances.

Of course, neither patriotism nor human willingness could have built the ships without the quiet teamwork of the technical men.

Now that the ships are being launched and delivered and put into service, I am glad to have this opportunity of thanking the technical men, and of emphasizing what I consider to be their best achievements, and of calling upon them for even greater contributions in connection with our new merchant marine.

Contribution of the Bridge Shops

The most notable contribution has been that of the fabricated ship. It is not conceivable that we could ever have built tonnage in such record-breaking time, without fabrication. And fabrication would never have been possible without the technical skill of our bridge and skyscraper industries to draw upon. In principle, it is thoroughly simple. In practice, however, it is most complicated. For the fabricated steel ship, when she is launched and delivered, represents the assembled materials from hundreds of mills and shops. No amount of ingenuity in designing or planning would make those materials fit into their proper places without the technical skill and experience which we found in establishments hundreds of miles from tidewater. No amount of patriotism, or willingness to break riveting records, could have assembled those materials in ships had technical accuracy been lacking. But the materials have come down to the seaboard from hundreds of shops, each making parts without knowledge of other contributing organizations, or of shipbuilding, and they have fitted with a refinement which is utterly new in the shipbuilding industry.

It is high time to review our technical results, and thank the technical men for their contribution, and to point out the solid groundwork they have laid for an American merchant marine and a real shipbuilding industry.

The reviewing of technical achievements may best be left to others who have been more directly identified with those details of the work in the Emergency Fleet Corporation and the shipyards. As Chairman of the United States Shipping Board, I can express my thanks and appreciation for the results, and testify to the resourcefulness and spirit of the technical men who have faced, not merely new problems, but unprecedented difficulties, shortages and handicaps, and won out against all odds. When the history of the war is written their achievements will be found as epoch-making and as characteristically American as the achievements of our fighting forces in France.

Future of Shipbuilding

New let us look a little into the technical future of our shipbuilding industry and our merchant marine.

Ship fabrication outside of the shipyard is unquestionably a success. Moreover, it is an American success, for no other country in the world possesses the technical resources of our bridge or skyscraper industries.

Is fabrication to be a permanent factor in our shipbuilding? Will it place us on a fair footing with other nations in cost of ship construction? Will it lead to the standardization of ships, both in hulls and equipment, and to standard practice in manning ships, and operating them, and turning them around in port?

I believe that all we have accomplished to date in this new industry points toward the fabricated standard ship. I believe that with our American facility in producing more bushels or tons or pieces per worker than any other nation, backed by the great ship-manufacturing plants which we have built for the war emergency, we shall be able to build ships as cheaply as any other nation—perhaps a little more cheaply. I believe that we shall operate ships largely with American officers and seamen, at American wages, and under American standards of living.

But we shall be able to do these things only if we apply American ingenuity and energy to the merchant marine as a whole. This is a national task. It calls for well informed public opinion and nation-wide interest in ships, first of all. Until we think of ships as we think of railroads we cannot have them—and when we think of ships in that way we can have anything.

This public opinion must be wise enough and strong enough to make all factors work together. The technical man, the ship operator, the seaman, the banker, the business man, the factory operative, the farmer, the salesman and the legislator must all work together for the common end. Ships are useless without cargo, cargo implies world trade, world trade is based upon international banking and investment, and all rest on national interest.

I believe that within the next year we shall see this national interest develop to such a degree that the American people will never again consent to be without ocean transportation facilities.

Somebody has said that none of us owns the United States—that our country was handed over to us by our forefathers and that we simply hold it in trust to be handed over to our children. Our forefathers left us America and also an American merchant marine. We have allowed the merchant marine to fall into decadence. We owe it as a duty to posterity to reconstruct it and hand it down once more. The bare facts about our new ships are so inspiring, and our world opportunities and obligations are so great, that simply to make these facts known during the next year should be to create the necessary interest in ships.

Now, most of the technical questions as to fabrication and standardization and operation, and the future of our shipbuilding industry, seem to me to turn upon the uses to which we shall put ships when we really want them badly enough and find work for them to do.

Shipping Development to Be Our Teacher

Great economies reside in the fabricated ship. But orders for our fabricated ships have been placed by the Government for war-time bottoms. When a government needs ships by the hundred, to transport troops, munitions and food, through a great standardized service, to the war zone, that is one thing. But if the Government, following the provisions of the Shipping Board act, disposes of these ships to private operators for service in carrying cargo and passengers on many different routes, that seems to me something entirely different. One operator will require cargo carriers of moderate tonnage and speed for charters. Another will want to put ships into scheduled freight service on regular routes. Still others will plan passenger-and-cargo liners to South America or Oriental ports, and still another may wish to enter the transatlantic passenger trade with fast ships of 20,000 or 30,000 or more tons. Therefore, the kind and quantity of service determine the type of ship and the number that can be operated. That in turn determines the kind and volume of ship orders and also the extent to which fabrication and standardization can be utilized.

Was it Liebig, the chemist, who about a hundred years ago confounded the chemical experts of his day by introducing the experimental laboratory? Up to that time, they say, chemists taught entirely by theory, lecturing upon what would happen if the substance A were mixed with the substance B —but never taking the trouble of mixing them. Then Liebig came along, as I remember the story, and actually mixed A and B, and they gave reactions never prognosticated in chemical theory.

Something of the sort is likely to happen when we actually begin operating merchant ships. It is easy to see that, with ships of our own, and a revival of our world trade, we shall create new American ocean routes. With the necessary backing of branch houses and branch banks abroad, the character as well as the volume of our trade will change, both in imports and exports. This suggests not only growth of our seaports, but probably a rearrangement of traffic to seaports over our railroads and inland waterways. Quite a number of conscientious citizens—usually inspired by local pride—are already theorizing about the effect upon this or that port. Other interested citizens are theorizing about navigation laws, seamen's wages, shipboard living conditions, and like matters—and very often from the viewpoint of self-interest. But just as it would have been impossible in 1865, when the Union Army marched up Pennsylvania Ave., to foresee the railroad development of the West during the following 15 years, much less carefully to arrange it all in advance by well planned theories, so I believe we are today facing a world expansion just as difficult to foresee in detail.

One assurance may be safely given the technical men who have gone into shipbuilding and who would like to continue therein—the assurance that when the energy of America turns to world channels, as it is now doing, it will give ample scope for technical activity. The world today is 18,000,000 tons of merchant shipping short of normal needs. That is, 4,000,000 tons more have been destroyed by submarines than have been built during the war and taken over from the enemy, and 14,000,000 tons shortage exists over what would normally have been built since 1914, without war. There are good grounds for anticipating that our shipyards will be busy during the next five years building up to the world's shortage, and that for five years afterwards they will be building for the world's growth. We shall need not only ocean tonnage, but increased lake tonnage, with vessels for inland waterways, tugs and barges for harbor use, and tonnage for coastwise trade, and repair and dry-dock facilities in keeping.

Let the Nation Become Ship-Minded

Types of ships and character of shipyards and construction will depend upon the demand. Along with these factors, let the technical men remember that the merchant ship is about to undergo almost startling improvements. We have the electrically welded ship just appearing over the horizon, as well as the motor ship operated with Diesel-type engines. These two modifications in themselves should keep the technical men busy during the next decade, for they promise radically new ideas in ship operation. The motor ship, for example, will give an unheard-of range of voyages, without bunkering, increased cargo space, improvement in working conditions and morale, and probably higher wages and general emancipation for seamen.

To sum up, briefly—American shipbuilding and the American merchant marine seem to me today comparable with our automobile industry when it was in its infancy. The technical men then set out to meet a known demand for road transportation with several distinct types of propulsion, such as the gasoline and the steam engine and the electric motor. The demand for vehicles far outran all anticipations. It determined the type of car, led the technical men into unforeseen fields of development, and, by modifying our whole national scheme of living, created an industry which has never since shown any signs of lagging. I believe that in shipbuilding and the merchant marine we are entering one more great field of unconditioned possibility.

Let us all work now to the end that this nation may become ship-minded, and the future will be ample enough for everybody.

Berth Construction and Side-Launching Practice in Great Lakes Shipyards

Berth Structure Simple—Timber and Concrete Foundations for Support of Ships—Concrete Launching-Way Stringers at One Yard—Keel-Blocks and Cradles Variously Arranged—Trip Shores To Release Ships

HIGH-PRESSURE shipbuilding in the yards of the Great Lakes has emphasized the simplicity and cheapness of berth construction and the saving of time secured by side launching. Ships can be laid down almost anywhere along a dock front, with little preparation of the berth. No submerged ways or other underwater work are required. The ways can be cleared and a new keel laid in much less than an hour. Building the ship on an even keel eliminates extra labor and delay in lining up the parts of the hull. Much ingenuity has been applied to the details of the method. It appears in modifications of timber berth foundations, the use of concrete substructures, quick-release keel-blocks of different forms, and variations in launching-way and cradle arrangements. The extensive enlargement of old yards and construction of new ones during the past two years because of the urgent demand for maximum ship output has created special opportunities for applying new ideas.

FIG. 1. LITTLE PREPARATION OF GROUND NEEDED FOR LAYING DOWN A SHIP IN A SIDE-LAUNCHING YARD

In a review of Great Lakes shipyard practice in *Engineering News-Record* of Nov. 28 and Dec. 5, 1918, pp. 978 and 1037, the various yards are listed and their main operating characteristics summarized. It may be referred to in connection with the present article.

Timber Berth Construction—Berths on firm fill require but little preparation of the ground for laying down a ship, as the view (Fig. 1) in the newest yard of the Lakes, the McDougall-Duluth Co. yard at Duluth, Minn., indicates. The keel-blocks are set on stringers founded on piles, as the soil is backfilled behind the timber dock front, but for emergency use this preparation could be dispensed with. In general, the company's timber berth construction is like that shown in Fig. 6 for its concrete berths, with timbers in place of the concrete caps. It is a longitudinal system.

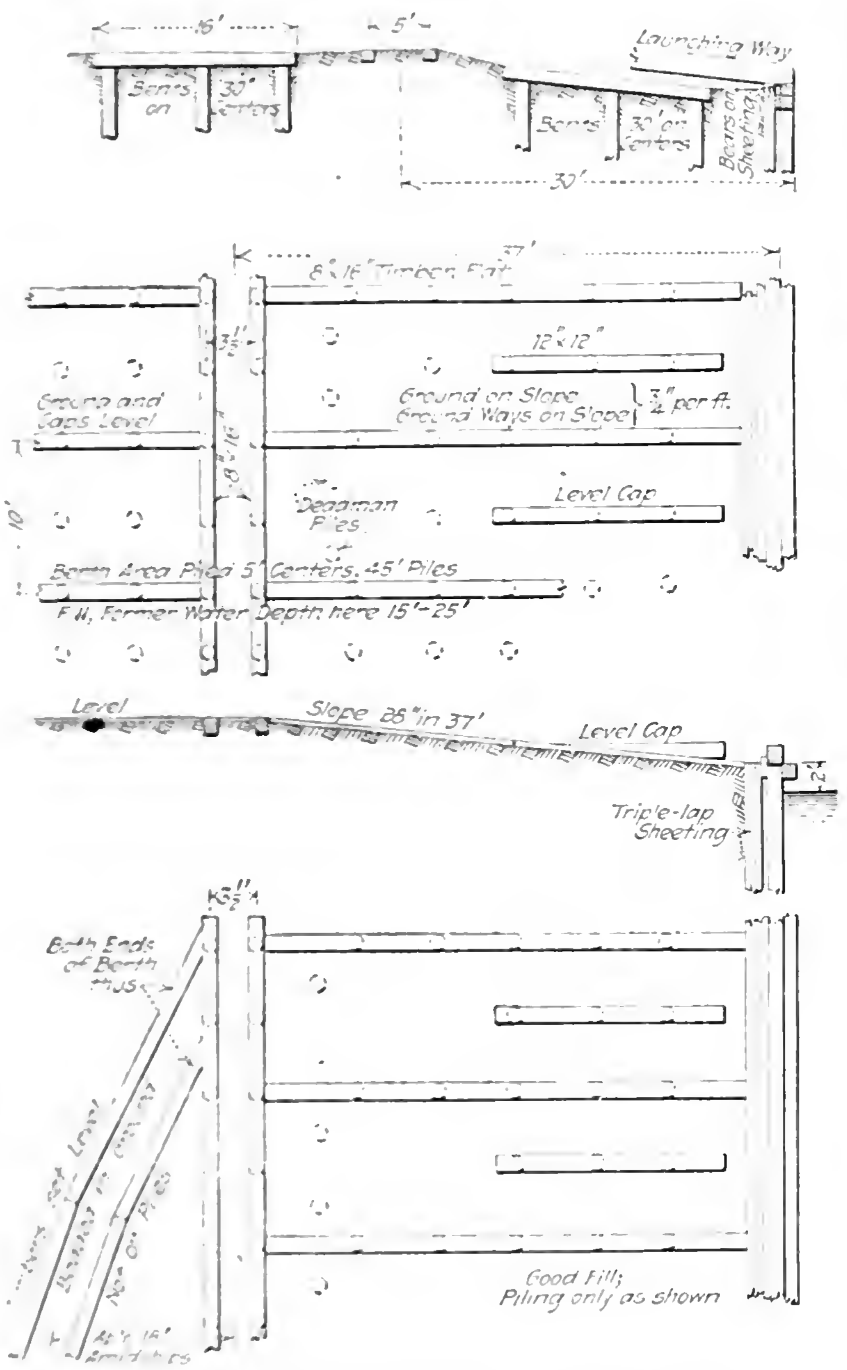
Several new berths of the Manitowoc Shipbuilding Co. at Manitowoc, Wis., are of the very simple type sketched in Fig. 2. A keel-block foundation consisting of two longitudinal stringers supported on piles runs down the center of the berth, and pile bents at right angles to the dock line give support for cribs or ways. The bents on the water side are set on a slope somewhat less than the launching slope of 1½ in. per foot, while those on the land side are level. The berth as a whole is not piled.

Somewhat more extensive foundation work, providing supports at 5-ft. intervals, was used in the four old berths, and was adopted again in building the new berths 5-9 of the American Shipbuilding Co.'s yard at Wyandotte, Mich., sketched in Fig. 3. Piles were driven 5 ft. on centers all over the berths; there was 20 ft. of water on the site of berths 7-9 only a year ago. The main bents are 10 ft. apart, and those on the water side have only half the launching slope, to give more room under the ship at the keel-block foundation level. Intermediate between the sloping caps are shorter level caps.

Stringer construction of a special kind is used on the land side of berth 10, the last one built at Wyandotte; its arrangement is sketched in Fig. 4. The water side of the berth is identical with that just described, except for the omission of intermediate piling, because of older and firmer fill. In the land half the ground is so firm that the stringers were laid without pile foundation. Direct bearing on the stringers of all main supports of the ship during construction is to be furnished by the arc-shaped pair of stringers. For supporting the launching ways, which carry load only an hour or two, blocking direct on the ground appears to be satisfactory.

McDougall and Toledo Have Concrete Berths—By substituting reinforced-concrete caps for timbers in some of the berths, the McDougall-Duluth Co. has produced a simple form of permanent foundation. It follows the stringer system on both land and water sides. Fig. 6 shows the layout and main dimensions. These concrete berths are the ones intended to be continued in service after the emergency shipbuilding is over.

More elaborate concrete berths are used by the Toledo Shipbuilding Co., Toledo, Ohio. They were built ten years ago, but are still practically in new condition, in spite of constant service. They consist of a complete gridiron of way bents and stringers or struts, arranged around a backbone formed by a heavy longitudinal girder under the keel-blocks. The waterside work is sloped to the inclination of the launching ways, and permanent 6 x 18-in. oak ways are bolted to the concrete caps of the transverse bents from this side. On the land side the concrete structure is level;



FIGS. 2 TO 4. VARIOUS FORMS OF TIMBER BERTH CONSTRUCTION USED IN GREAT LAKES YARDS

Fig. 2—Timber berth construction at Manitowoc. Fig. 3—Piled substructure of berths 7, 8 and 9, Wyandotte Yard. Fig. 4—Combined transverse and stringer type used at berth 10 at Wyandotte

hinged launching-way sections here can be raised up to the way slope. After a launch, they are dropped down to give free working room for setting keel-blocks and laying a new keel. Later they are taken out, at leisure, to leave the berth space clear, being easily replaced when preparations for the next launching are to be made.

Protection covers are provided for the fixed way timbers (on the water side), but they are rarely used. Lugs for launching-trip supports are formed in all the transverse concrete caps, so that the trip shores used in releasing a ship at the time of launch can be set anywhere.

Firm support is afforded by the concrete structure for the outboard rail of the gantry cranes with which the Toledo berths are equipped. This rail can be removed or replaced in a few minutes' time, and by reason of the firm foundation no time is lost in lining it up.

Wedge Keel-Blocks Save Time in Launching—While building, the ship is supported by keel-blocks (Fig. 1)

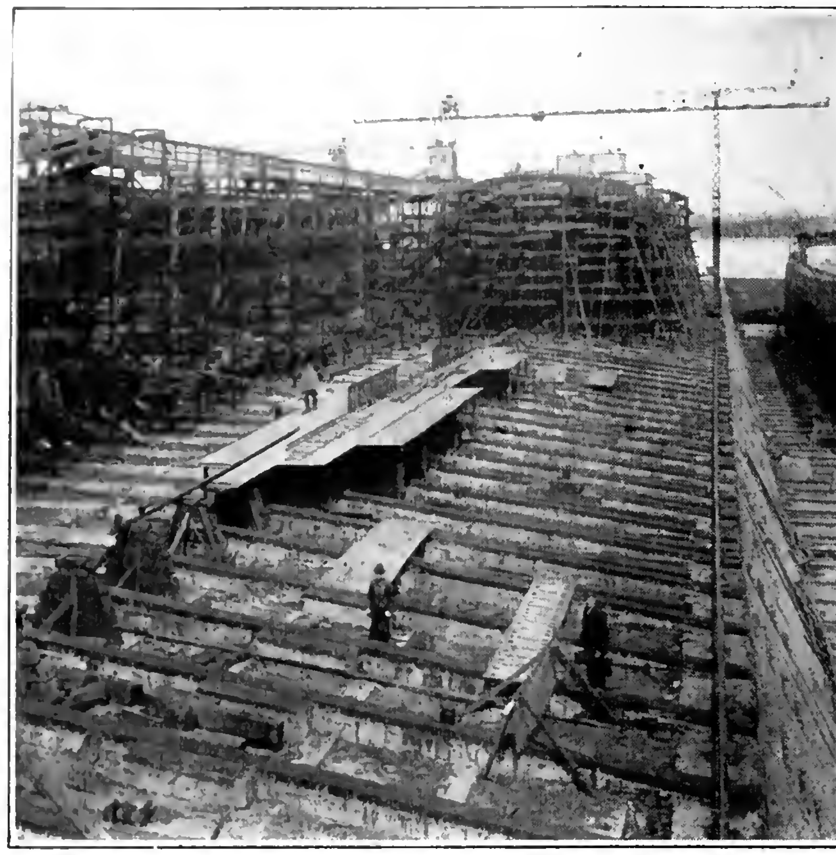


FIG. 5. TOLEDO YARD HAS FIXED LAUNCHING WAYS ON CONCRETE BERTH FOUNDATION

and props or shores just as in end-launching practice, except that it is level in both directions. Safety cribs are built up near the bilges as the ship grows, to give it stability independent of the shores. In the Cleveland yard of the American Shipbuilding Co. cribs are used on the water side only—three cribs, each 4 or 5 ft. square. Most other yards place cribs on both sides, and use eight to twelve in all.

As all the fixed supports must be taken out for launching, and their load transferred to the sliding blocks or cradles resting on the ways, special devices for releasing their load are used in many yards. The shores carry each only a small amount of load, and they are therefore easily knocked out after the ship has been wedged up on the cradles. The keel-blocks, however, which carry most of the load, are so held between foundation and ship that they cannot be knocked out. At Cleveland the top block, on which the flat keel rests, is a piece of 12 x 12 about 18 in. long, and in order to take the load off the keel-block at launching time this upper block is split out by steel wedges. For 30 keel-blocks the operation of splitting out—working at two simultaneously, so that there are 15 operations—takes the better part of an hour and keeps a large crew busy. Quick-release wedges have, therefore, been devised in several forms and are widely used.

Wedge blocks of the type shown by Fig. 10 are used in many of the yards either on the end blocks only or on all the keel-blocks. At Cleveland they are used only on the four end keel-blocks at stem and stern and (after the link is unbolted) they are knocked

out with a ram after the other blocks under the ship have been cut out—this being the final step in transferring the ship's weight to the cradles and putting strain on the trip-shore ropes so that the ship will start when the ropes are cut. The McDougall-Duluth yard uses these wedges on all keel-blocks, and so saves the work and delay of splitting out blocks; it also uses them on the safety cribs, as sketched in Fig. 11.

An ingenious double-wedge block, the Thompson keel-block, has been adopted at Manitowoc. This was originated by one of the company's carpenters and patented by him. It provides not only for quick release, but also for easy adjustment to proper height at the time of laying the keel, or later in replacing a keel-block after it is taken out for riveting the keel directly above. As sketched in Fig. 12, it consists of a bottom wedge whose upper sloping face is roof-shaped with longitudinal ridge, and two upper blocks bearing on the side slopes of the roof surface. The upper blocks are bolted together, but for releasing, after the bolts are taken out, they can be knocked away easily. When in place and bolted up they may be shifted lengthwise on the lower wedge for height adjustment. An important saving in launching time has been realized through the use of this block, as explained farther on.

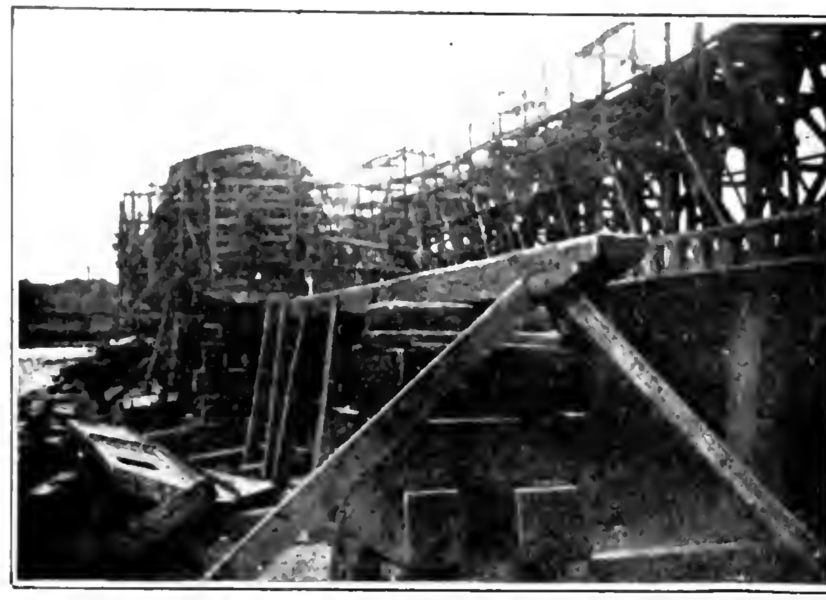

FIG. 8. TEMPORARY SILL LAID ON SAFETY CRIBS TO CARRY BOTTOM SHELL

Simple wedge blocks are used at the South Chicago yard of the Chicago Shipbuilding Co., as may be seen in Fig. 15. They are sketched in Fig. 13.

Toledo also uses blocks wedged on both sides, as can be seen also in the view, Fig. 5.

Launching Ways and Cradles—Twice as steep a launching slope is used in side launching as in end launching—$1\frac{1}{4}$ to $1\frac{1}{2}$ in. per foot, as compared with $\frac{5}{8}$ in. to $\frac{3}{4}$ in. The ship must acquire a considerable velocity to make its drop at the end of the ways properly, in view of the retardation produced by the ship's outer bilge entering the water just before the final drop (Fig. 16). Fig. 9 shows the general declivity of the launching ways as set for a 600-ft. ore steamer at Ecorse. A nearer view of the way surface as pre-

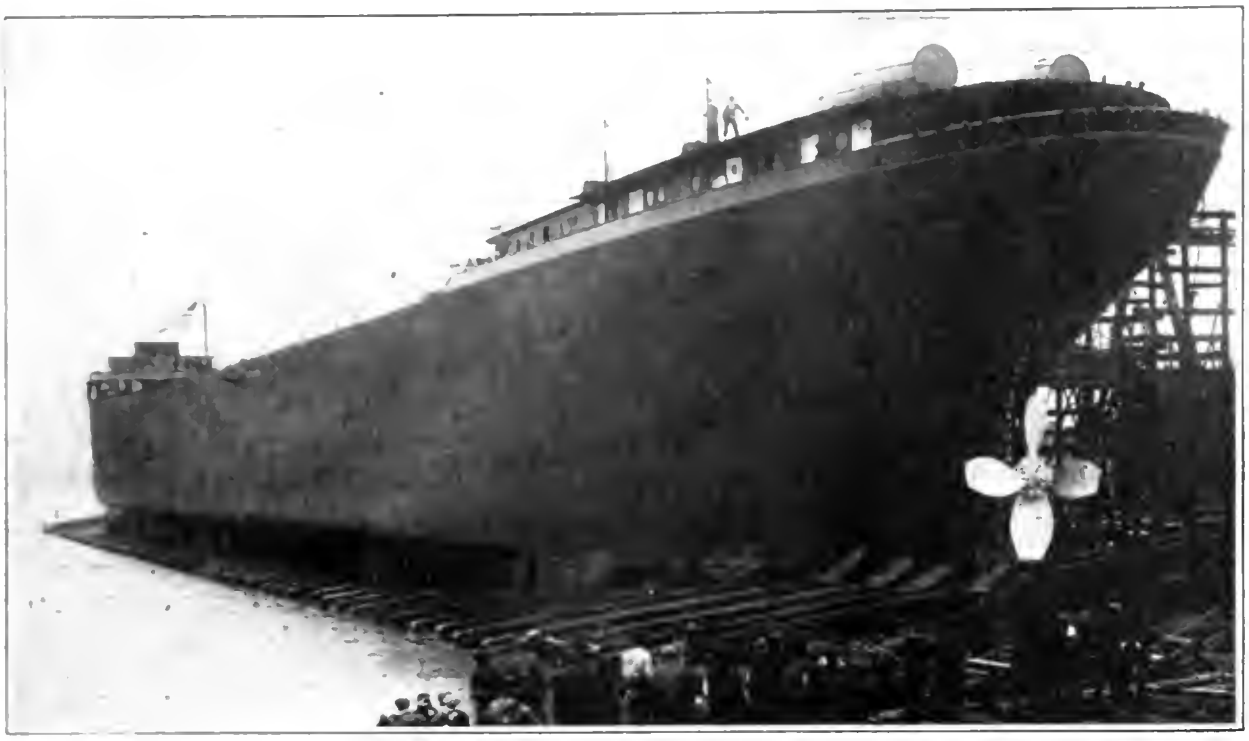

FIG. 9. TEN TRIP SHORES USED FOR 600-FOOT LAKE STEAMERS; EMERGENCY FLEET VESSELS REQUIRE ONLY FOUR

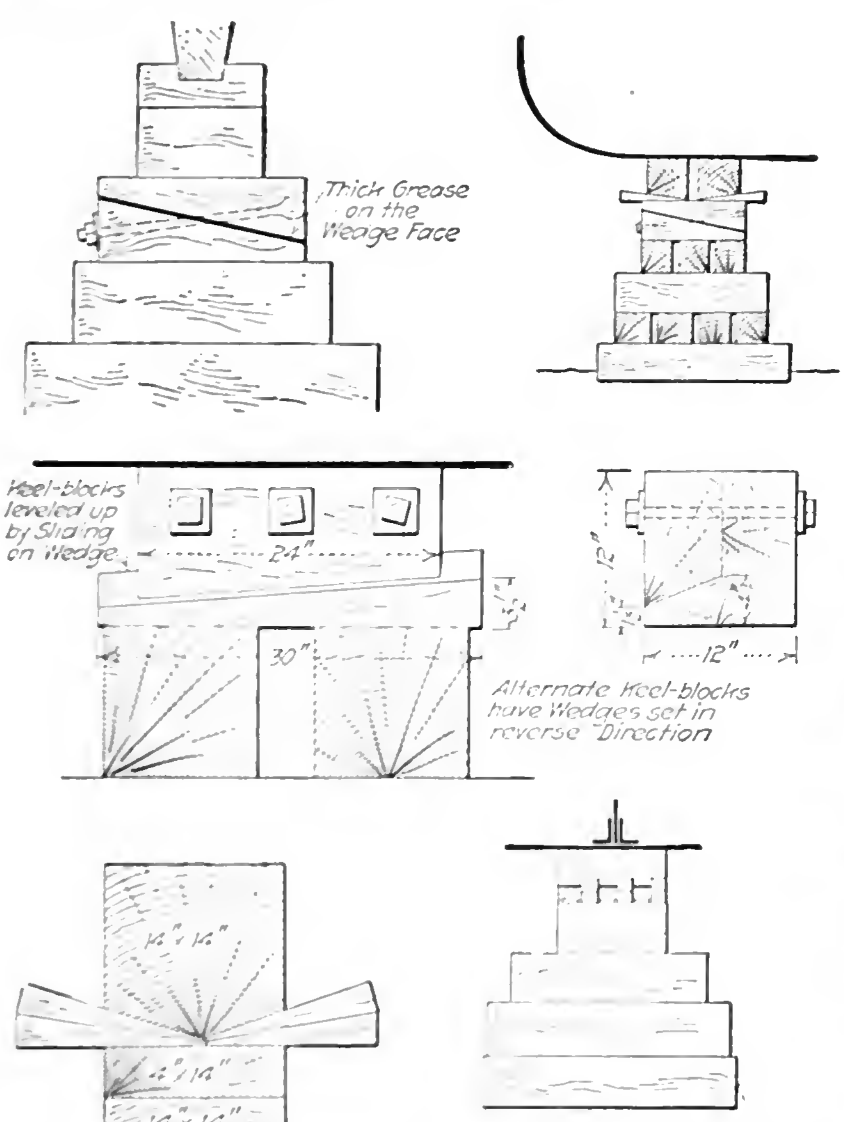
pared for one of the short Emergency Fleet ships appears in Fig. 17.

Timbers 18 x 24 to 20 x 20 or 24 x 24 are used for launching ways (Fig. 18). They are spaced 10 to 12 ft. apart (for example, 12 ft. at Cleveland, 10 ft. at Toledo and Wyandotte), in uniformly spaced arrangement, except at Duluth, where the interesting twin-way arrangement shown by Fig. 19 is used.



FIGS. 10 TO 13. WEDGE KEEL BLOCKS USED AT CLEVELAND, MANITOWOC, SOUTH CHICAGO AND TOLEDO

Fig. 10—Wedge block with locking link used on end keel-blocks (Cleveland). Fig. 11—Safety crib with quick-release wedge block (McDougall-Duluth). Fig. 12—Manitowoc duplex wedge keel-block. Fig. 13—Arrangement of wedges in keel-blocks at South Chicago.

Blocking under the way timbers, directly on the ground, forms their foundation. The forward end of the ways is usually supported on the bulkhead wall of the dock. The regular practice is to let the forward end of the timber bear on the main 12 x 12 pile cap of the dock front. At Manitowoc the timber is made to bear on the sheetpiling of the bulkhead and is kept clear of the pile caps (Fig. 2), as the former is considered better able to take the extra load as the ship passes over. At Ecorse, however, the ways are not allowed to bear on any part of the bulkhead, but are placed to clear the cap timber by about 3 in. (Fig. 20), the support being given wholly by blocking on the ground. Relatively light bearing pressures are developed between the sliding cradles and the ways. With the Emergency Fleet ships, weighing not over 1200 tons at launching, the total area of sliding surface is 250 to 400 square feet, giving three to four tons pressure on the sliding surface. With long Lake ships the pressure may be 9 to 10 tons per square foot. The American Shipbuilding Co.'s standard arrangement of ways and cradles, used with minor modifications at each of the company's six yards and representing fairly closely the general Lakes practice, is shown in Fig. 18, which exhibits the relation of ways and cradles to the ship and the edge of the dock. The ways do not extend down into the water so as to give support to the ship until it is floated off the cradle (as in end launching), but stop short at the edge of the dock. Launching involves a tipping of the ship just before the vessel finally leaves the ways, as the view Fig. 16 clearly portrays. The action is as sketched in Fig. 21, representing a

FIG. 15. WEDGE BLOCKS AT CHICAGO USED AT EVERY KEEL SUPPORT

FIG. 16. LAUNCHING WITH LOW DROP AT LORAIN; THE "LAKE DEVAL" WAS BUILT IN 24 WORKING DAYS

diagrammatic transverse section through the ship at the time of launch. Supported on its five lines of cradles, the ship when released moves down the ways from position A to positions B and C. By the time position C is reached the two lines of cradle

FIG. 17. SHIP TRANSFERRED TO CRADLES READY FOR LAUNCH (CLEVELAND)

on the water side, 1 and 2, have already passed over the ends of the ways and dropped out. At position C, the center line cradle K also drops out; the vessel then is unbalanced and pivots on cradle 3. While tipping to position D and beyond, it continues to move forward and strikes the water in position E. Forward movement continues, and the resistance of the water applied at the bilge increases the tipping moment and tends to relieve the load on the rear cradles. When cradle 4 drops out, the vessel soon settles to an even keel.

Ordinarily, the end of the ways is only a foot or two above the water surface, so that conditions are fairly represented by the sketch, Fig. 21. Much higher drops, however, occur at South Chicago (4 to 5 ft.) and at Buffalo. A new berth at Buffalo has a dock front about 7 ft. high, so that the keel of the ship is 10 to 12 ft. above water at the moment when the drop begins. At low water in the extreme case the drop is about 12½ ft., and this was the condition at the time the "Lake Delancey" was launched, on July 4. Fig. 23 shows how the ship took the water.

The cradles on which the ship moves down the ways are relatively simple arrangements of blocking in the flat-bottomed ship now being built. A row of center-line cradles the full length of the ship and two shorter rows of cradles on either side of the center line constitute the common arrangement. Six cradles are used at Duluth (Fig. 19). Wedges in the upper tiers of each cradle (see cross-section in Fig. 18) are the means for lifting the ship to transfer the weight from the shores and keel-blocks to the cradles. At Cleveland the cradle on the land side, which comes just inboard of the turn of the bilge, is blocked solid from way-timber to ship, and the wedges are set under the way-timber.

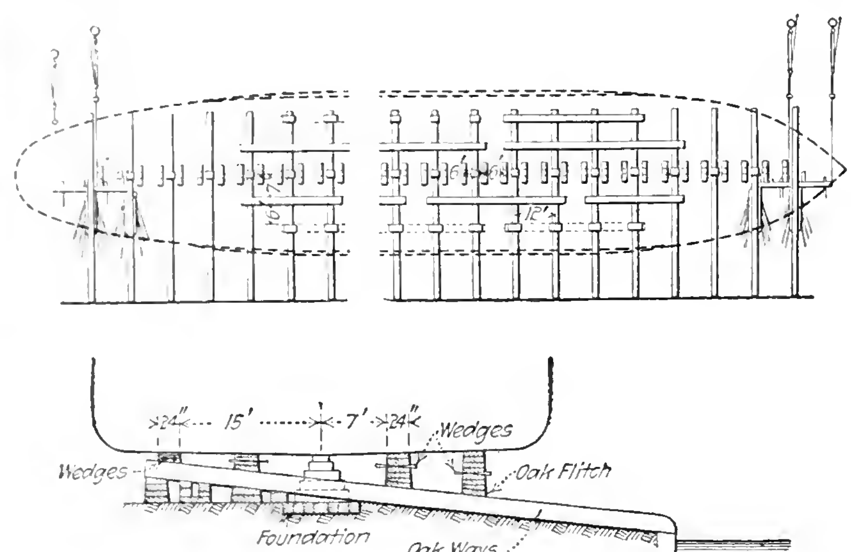

FIG. 18. TYPICAL ARRANGEMENT OF KEEL-BLOCKS AND CRADLES, AMERICAN SHIPBUILDING COMPANY

This is done partly because when put under the way, the wedges tend to lift its upper end.

More common practice has all the wedges above the ways, (sketched in Fig. 24) as at the Wyandotte yard. Single wedges are used in the cradles, except in the center-line cradle. The two cradles on the water side are tied together transversely by tie planks about mid-height, for greater stability.

Oak or maple sliding blocks are used on the ways, of a length not greatly exceeding the width of the ways

(usually 24 in.). In the twin-way arrangement used at Duluth, the sliding blocks or "butter boards" extend across the two ways of the twin pair. Their length of 8 ft. gives 6 in. of projection over the sides of the ways. Using the long butter boards and having two ways in a pair is believed to offer greater security

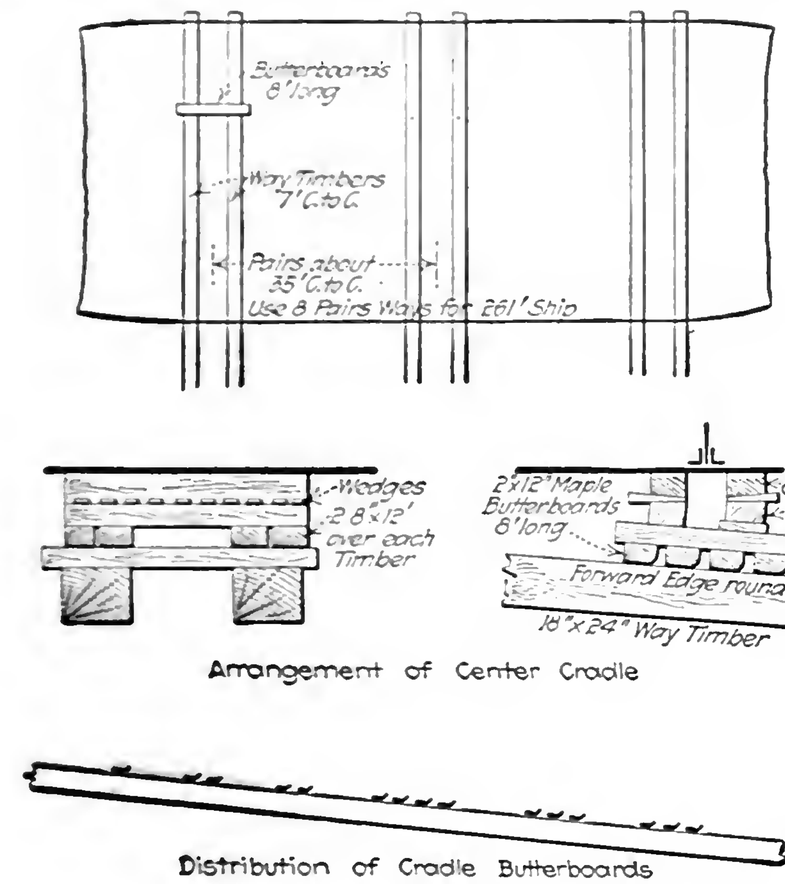

FIG. 19. TWIN WAYS AT DULUTH

against the cradles leaving the ways in case one end of the ship is released before the other and the ship skews during the launch.

Releasing the ship is accomplished by cutting the ropes holding trip shores constructed according to the drawing, Fig. 25. Each trigger consists of a lever parallel to the center line of the ship, one end resting against an abutment arranged on the side of a way timber and the other held by a bight of 1½-in. rope securely anchored inshore. This lever is about 10 ft. long. About a foot from its abutment or fulcrum end

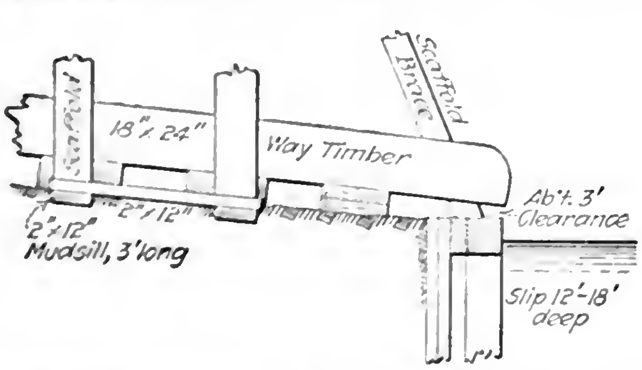

FIG. 20. ECORSE WAYS ARE KEPT CLEAR OF BULKHEAD

a short post footing against the lever bears against the keel of the ship or a ledger-block fastened to the side of the ship. In launching the 600-ft. ore steamers which constitute the main carriers of the Great Lakes, often four trip shores were placed at each end of the vessel and two near the center, making a total of 10 that had to be released simultaneously. The short 261-ft. vessels being built for the Emergency Fleet Corporation are launched with two trip shores at each end, four in all, arranged as sketched. The vessel shown in Fig. 9 is held by ten ropes, the four stern trip

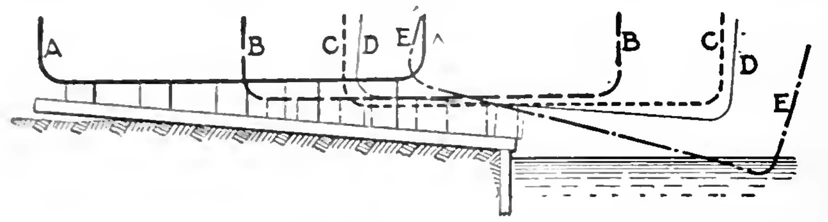

FIG. 21. SIDE-LAUNCHED SHIP TIPS AS THE CENTER-LINE CRADLES GO OFF WAYS

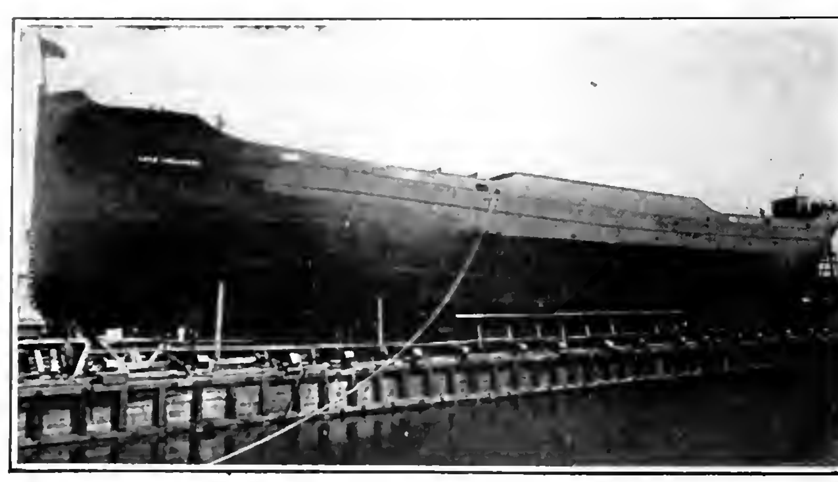
shores being visible in the picture. The two trip shores used for the Emergency Fleet vessels show clearly in Fig. 17, a view of the "Lake Alvada," launched Aug. 18 at the Cleveland yard.

As shown in Fig. 25 (see also Fig. 18), the thrust of the trip shores against the launching ways is absorbed by raking struts bracing the way timber which serves as abutment. An anchorage arrangement used at Wyandotte, shown in Fig. 14, transfers this thrust from the insecure ground at the berth to secure anchorage timbers some distance back. The same timbers serve for holding the ropes by which the long end of the trigger lever is held.

Hydraulic or screw jacks are placed against the side of the ship, one near each end, to start the ship from its static conditions before the ropes are cut. Most yards pump up these jacks in every case, to make sure



FIGS. 22 AND 23. LAUNCHING FROM HIGH DOCK—BUFFALO YARD CONDITIONS INVOLVE DROP OF 10 TO 12 FEET

that no obstruction is present and that the ship will start promptly.

Typical Launching Procedure—Transferring a ship from its fixed blocking to the cradles and launching it is an operation of an hour or an hour and a half. The following description of the procedure is from notes taken during a launching at the Cleveland yard, but the steps are substantially the same in all the

Lakes yards. At the start of the work described, the vessel rests on its keel-blocks, on one or two rows of posts or shores near each bilge, and on three to twelve safety cribs, also located near the bilges. The launching ways are in place, all the cradles are on the ways, with launching tallow between the contact surfaces, and are lightly wedged up against the ship.

Putting the entire launching gang on the water side of the berths, the launching boss clears this side of its fixed supports, as the first step. The men working in pairs, drive in the wedges of both lines of cradles on the water side of the ship; after a first "rally" of two or three minutes, followed by a breathing spell of the same length, a second rally transfers enough load to allow the shores to be knocked out. Simultaneously with removal of the shores, the cribs on this side of the ship are taken out by knocking out the wedges in the blocking. The water side of the ship is then free and on its cradles. Repeating these operations on the

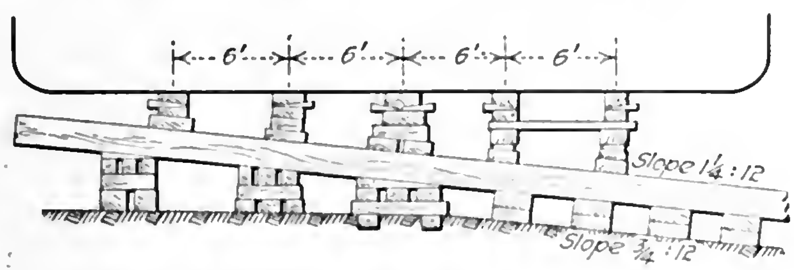


FIG. 24. CRADLE ARRANGEMENT AT WYANDOTTE

land side clears the ship of all fixed supports except the keel-blocks.

Trip shores and releasing ropes were placed on the previous day, and the ropes drawn up by tackle to a good strain. Everything is therefore ready for the removal of the keel-blocks. Beginning at the center, the blocks are split out, in pairs, first the two blocks amidships, then the one forward and the one aft of these, working on successively to the ends of the ships. When all are split out, the four end keel-blocks supported on wedge blocks tied by linke (Fig. 10) still hold the ship. The links are taken out and eight squads of men with heavy planks as battering rams get in position to knock out the eight sets of wedge blocks.

For even launching, the four ropes holding the ship must be cut simultaneously, and the ship must be ready to move. The latter requirement is assured by giving the ship a slight shift by means of the jacks before cutting the ropes. To make sure that the cutting goes on as a single blow, four axemen, one at each rope where the rope passes over a chopping block, work in conjunction with the launching boss and his two assistants in such a way that one signal is carried to all four. Close to each end of the ship is stationed one of the assistants, where he is in plain view of the two axemen at that end. Halfway between them, and in a little, back from the ship, the superintendent stands on a platform or box, in clear view of the assistants. Each of the latter has tacked to a rail in front of him and facing the boss four sticks or semaphore markers.

At a signal, the first ram gang at each end knocks out the wedge keel-block farthest from the end of the ship; the moment it is clear the assistant in charge turns down the first of his four markers. The other wedge blocks are then knocked out in order. As the last supports go out, the cutting ropes should show the strain of the ship's pull, and the last of the four markers is not turned down until the assistant in charge has made sure that this is so—in other words, that the ship is "alive"—otherwise, the jacks are applied to start the ship.

When the turning down of the last marker informs the superintendent that both ends are clear and alive, he slowly raises his outstretched arms, a signal to the axemen to raise their axes. The assistants at the ends follow him in this movement, and the axemen in their turn. After a moment's pause, the launching boss brings down his arms, and the signal goes through the chain to the axemen and results in a simultaneous cut on all the ropes.

Preparation for the launch may be started as soon as the ship's bottom is riveted; after this time there is no more occasion for working under the ship, so that ways and cradles do not interfere with anything. Ordinarily, however, no ways are set until about two weeks before the intended launching date, and if further delay is desirable the work may be started as late as a week before launching.

Launch Ship in Ten Minutes by Help of Wedge Keel-Blocks—Remarkably fast work in launching is accomplished at Manitowoc by a change in procedure which was developed after the adoption of wedge keel-blocks of the type described. The last half dozen launchings

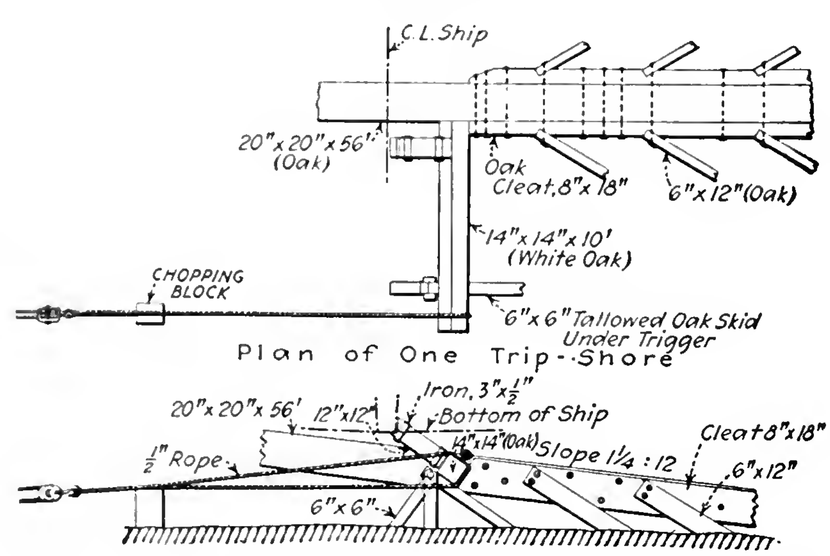

FIG. 25. TWO TRIP SHORES AT EACH END RELEASE THE SHIP; FOUR ROPES CUT SIMULTANEOUSLY ON SIGNAL

at this yard were made in about 10 min. each, from starting time to the moment the ship struck the water. A description of the method is contained in the following memorandum of Elias Gunnell, president of the Manitowoc Shipbuilding Company.

"The launching gang hardens up the upper side of the vessel and removes all shores and cribs on that side, in advance, so that on launching day all that is necessary is to harden up the lower side and remove the lower or river-side cribs and shores. There is no attempt to raise the vessel off the keel-blocks. After taking out the bolts a wedge is driven between the two pieces of the upper block, and the block comes free. Our last six launchings averaged just 10 min. from starting time to water. This time could be cut, but counting on the regular run of launching gangs that we use in these days, bolters and helpers, it is good time."

What the Year Has Taught About the Concrete Ship

Much Learned Regarding Design and Construction—Future Depends on Ability To Build in Cost Competition with Steel—Structurally, Ship Is Success

(Editorial Review)

WHEN the United States entered the war the concrete ship was unknown in this country. When the armistice was signed the Government itself had over a hundred ships and barges under contract, one American vessel had finished a 12,000-mile voyage ending at New York, and millions of dollars had been put into yards where vessels from 7500-ton oceangoing tankers down to 500-ton canal barges were being built. This new industry was developed practically in its entirety by engineers and contractors who had before no experience in ship design or construction. Whatever future it may have will undoubtedly remain in the hands of the concrete constructor who brought to the problem native ability and experience in the general art of concrete construction. Now that the war is over and the immediate critical need which developed the concrete-ship idea has passed, many are asking what has been learned in the past year and what are the chances for the concrete ship as a permanent competitor of the vessel of wood or steel. Even now it is too soon to do more than review certain obvious conditions and developments and to set down briefly some of the things that have been learned.

The history of the concrete ship has been told in these pages during the past year. It suffices now to repeat that the development was, early in the war, taken over by the Concrete Ship Section of the Emergency Fleet Corporation, and that the Shipping Board soon refused to allow any ships to be built for private account. In consequence, though hundreds of engineers interested themselves in the study of the problem, the only ships contracted for were those built under the auspices of the Fleet Corporation, except some small power boats and lighters for the War Department, towboats for the Railroad Administration and the Navy, and a few barges for private owners. The Concrete Ship Section conducted many studies in design and construction and, though handicapped by what at best may be termed a lack of sympathy in some quarters in the Fleet Corporation, is, together with its associated contractors, entitled to the major part of the credit for what has been done.

Design Based on Theory, Not Rules

Many pages might be written on the design of the concrete ship. In fact, many pages have been written recently. They all reduce to the fact that the usual ship-design methods have been used to determine bending moments, although strain studies now under way on actual ships may modify these methods in the future. The difficulty in design comes in proportioning members to meet the assumed moments according to theory rather than according to standardized rules based on past practice and performance, as has been the practice with steel ships. Distribution of shear in the shell has been particularly bothersome, and has been met in some cases by assuming larger unit stresses than have been common, though apparently justified by incomplete tests, and in some ships not yet beyond the design stage by radical rearrangement of the frame so that the shell takes no shear.

Construction Problems Many

Ship lines in the early ships, particularly in the "Faith," were very crude. The opposite extreme was reached in the first Government ship, the "Atlantus" launched last month at Brunswick, Ga., which takes on the appearance of a yacht and which, due to the very extreme fairing, was difficult to build. Between the two extremes lie the latest Government ships which have sufficient curving of the lines to present a good appearance, but which are not particularly complicated in form.

It is in construction of the concrete ship that most has been learned. It can be definitely said, for instance, that the claim of the violent advocates of a year ago, that no skilled workmen would be required on a concrete ship and therefore it could readily be built anywhere with little difficulty, is not true. No one who has gone through the first few months of building one of the large concrete ships will deny that the work requires the highest type of skill, and that even the training gained on reinforced-concrete buildings is inadequate—because, primarily, of the greater accuracy required in placing the steel and forms and of the greater congestion of the steel in the forms. A concrete ship does not require as many kinds of skilled labor as does the steel ship, but the labor that it does require must be of the highest type.

Placing Steel Difficult and Expensive

Difficulties which arose in the construction were mainly those connected with the placing of the steel in the narrow, congested forms. Contrary to many expectations, the construction and erection of the forms themselves have not proved overly difficult. It was, of course, a problem different from that met in building construction in that the whole form structure, inside and out, had to be erected complete before any concrete pouring started. In addition, all of the forms so erected had to be arranged in such manner as to allow free access inside the boat during the pouring, and a ready method of stripping, so as not only not to injure the concrete itself, but to preserve the forms for subsequent use. This has been met quite successfully and, so far as shown by figures given out, quite economically.

Placing the steel has been the critical element in the construction of both barges and ships. Bending itself has been very difficult. The curves are complicated and diverse, so that templets have to be changed frequently. Much of the steel is large in diameter. In none of the boats so far built has the cost of this work been reduced to what it may be ultimately. Placing the curved steel has still further complications, not only on account of the difficulty of fitting it to the curves in the forms, but

also because of the accuracy in its spacing which is required. Undoubtedly, with practice, the bending and placing of steel will be made cheaper. Indeed, it must be made so if the cost of the ships is to be brought down to a competitive basis.

Mechanical Hammering an Innovation

The element of mixing and placing the concrete has not given the trouble that was possibly anticipated. In fact, it has been shown that getting the concrete to the forms themselves is a minor detail, and no great elaboration of plant is required to insure it. The narrowness and the general congestion of the formwork make it difficult to place the concrete in the forms, so that delivery to a nearby point from which shoveling to the forms may be done requires only a moderate speed and quantity of concrete.

The placing of the concrete, however, could hardly be done at all successfully without the use of the air or electric hammer, which has been introduced by the Concrete Ship Section in the making of all of the Government ships. As stated above, all the forms in the ship must be up before the concreting starts. This leaves many bends and turns inside the forms around which the concrete must be led. The ideal consistency attempted by Mr. Edison in his concrete-house project of a decade ago is what the concrete shipbuilder would like. Lacking this so far impossible mixture, the hammer is the next best thing. Several of these hammers battering the inside forms during the pouring of the concrete permit the use of considerably drier mixture than used to be employed in thin, heavily reinforced wall work, and performs almost incredible feats in leading the concrete into the corners of the forms.

Behavior Tested in But One Ship

So far as performance of the concrete ship is concerned, our whole dependence is on the freighter "Faith," which was dry-docked in New York in November after a voyage down the Pacific to South America, up to New Orleans, thence to Havana, and up to New York. Barring the rather serious cracks in the deck where a winch was seated in a place not intended for it, the ship, to all outward appearances, is intact. All rumors to the contrary notwithstanding, her hull is free from anything but minor hair cracks, and the outside surface, which has been subjected to sea-water action for nine months, is in as smooth and unpitted a condition as any concrete in the dry air of the interior of a building.

The "Faith" is as "ugly as original sin." Her structural design, according to those who have investigated it, is susceptible of considerable improvement. She is heavy and therefore undoubtedly uneconomical, but she is an oceangoing concrete vessel which has successfully passed a long sea test.

What is the future of the concrete ship? It is still too early to draw definite conclusions, but the experience of the year seems clearly to indicate that structurally the problem is solved; improvements are bound to come, but the fears of a year ago as to difficulties in erection and dangers in service need not deter progress. The future today is bound up in costs. Competition with steel ships rests on cost per ton of freight carried, which is tied up to original cost plus carrying capacity per ton displacement. The concrete ship will have to be built sufficiently cheaper than the steel ship to counterbalance the extra cost of the dead weight, which is still higher than for the steel ship, despite the advantages of the new light aggregate.

This light aggregate, an artificially burnt clay developed by the Concrete Ship Section, gives promise of being a most important step forward in concrete-ship work. Weighing less than water, it produces in a 1:2 mixture a concrete having a weight of 100 lb. or slightly more, and a strength at 28 days of 4000 lb. By its use it is possible to produce a concrete ship with a carrying capacity to dead-weight ratio only slightly below that of the steel ship—so close, in fact, as to bring the two types in competition.

So far figures for the oceangoing ships have not been produced showing the closeness of this competition, but in towboats they have been made. Barges of identical dimensions, for instance—one of steel carrying 600 tons and one of 150-lb. concrete carrying 500 tons—have operating profits practically equal, using actual contract costs and identical freight charges. A barge built with the 100-lb. concrete would naturally show greater profit.

The costs of the seagoing ships have been confused by a number of things. The "Faith" is a private venture for which costs are not available. The first Government ship, the "Atlantus" will prove to be inordinately expensive. Until official explanations are given out, exact causes cannot be stated, but it seems evident that the slow construction and high cost were due to a combination of inexperience in concrete design and construction, a lack of proper plant equipment due to the fact that only one ship was to be built in the yard, a possibly praiseworthy experimentation with methods and devices, and—so many reports go—shiftless labor.

It is unfortunate that this first Government ship should have taken so long to build and have been so expensive, because it will undoubtedly be used as an argument against future development. Meanwhile, the other Government yards have been built at large expense for eight ships apiece. The big ships being turned out from these yards apparently are being built cheaply enough to permit them to compete fairly with steel vessels, *if the proper proportion of plant charge is assessed against each.* The responsibility for giving out full and authentic cost data on the concrete ship rests squarely on the Emergency Fleet Corporation. Only by knowing these figures can shipowners or prospective builders form their judgment of the practicability of this new kind of vessel.

Concrete shipbuilders are learning their trade in the hardest of schools. They cannot produce as efficiently or as cheaply now as they will after their first few units are turned out. It is going to take the backing of the Government or of courageous spirits such as those who financed the "Faith" to continue the big concrete ship as a commercial proposition, but the future is bright for any such venture. For the small barge, car-float or lighter, on the other hand, the field seems more immediately open. A number of contractors have learned to build such boats, and their experience should be worth much in reducing costs to a competitive basis.

Fabricated-Ship Construction in One Year's Experience

New System Now Thoroughly Tested by Large-Scale Working Has Proved Adaptable And Free from Inherent Difficulties or Elements of Excess Cost

(Editorial Review)

SINCE the "fabricated-ship" enterprise was launched by the Emergency Fleet Corporation as a war-time experiment, 15 months ago, actual hull construction has been in progress for a full year. The system has undergone a thorough, practical trial during this time. Its feasibility has been shown by the launching of a large number of fabricated ships, and the completion and acceptance of half a dozen.

No report on the outcome of this gigantic experiment has been made by the Shipping Board. Since, under the now changed conditions, the value of the ship-fabricating system depends on how it can maintain itself in commercial shipbuilding service, some notes on the practical working of fabricated-ship construction collected by representatives of *Engineering News-Record* are summarized here.

The "fabricating" system is characterized by the fact that the yard sublets to bridge-building shops the punching, shearing, planing, countersinking, scarfing, assembly riveting (so far as practicable within shipping limits), and in some cases the bending or curving of the plates and frames and other parts of the ships' hulls. This means that the work is done at a distance from the yard. It requires sending the necessary construction data from yard to shop by drawings or templets, or both, and obviously demands that the advance information be so precise that the parts will fit together when erected. Extensive changes in ship design, plant layout and construction methods have developed to suit.

Shipping Board Report on Method

So far as the Shipping Board's report (issued Dec. 1, 1918) indicates, the success of this new shipbuilding method is just as problematical as it was a year ago, for the subject is dismissed with the following remarks: "Summarizing the facts in connection with the fabricated ship, we find that the development of the structural steel ship and the enlistment, for the task of shipbuilding, of the engineering experience, the organizing ability, and the mechanical skill of the trades which built our bridges, our great office buildings and other commercial structures, may be counted upon to add from 3,500,000 to 4,000,000 tons of ships each year to our total.

"Three very significant facts should be noted with reference to this plan: First, if the yards had depended on their own fabricating shops and facilities it would have been impossible to develop an equal amount of new shipyard capacity for the manufacture of machinery and equipment, in two or three times the number of months required under the plan adopted. Second, without the ship-fabrication work and the ship equipment orders, hundreds of shops throughout the country might have been closed down, with immense losses to owners and employees. Third, the expense of new shop installations at the yards, if they had been built under the old system, would have run into hundreds of millions, and further concentration of the additional workers in the already overcrowded shipyard districts would have required many additional millions for housing."

Over $200,000,000 of public funds has been invested in the bridge-shop-fabrication system of shipbuilding, besides a large amount of private money. Exclusive of the latter item, the cost to date comprises $100,000,000 expended for shipyard plant and $100,000,000 or more for material and labor used in shipbuilding. The report of the Shipping Board from which these figures are deduced states that the ultimate expenditure for fabricated ships on present contracts will be nearly $500,000,000, so that with the plant cost a total investment of $600,000,000 will be chargeable to the fabrication system.

Quality of Work Excellent

All evidence obtainable testifies to the success of the fabricating method in point of quality of work. "The quality of the work is excellent; the possibility of delay constitutes the only danger of the fabricating system," says one yard manager. The results obtained at another yard are described by the statements of fitters and bolters of many years' service in old-line shipyards, that they have never handled steel that fits as well as the bridge-shop steel. An especially critical judge of shipbuilding matters, who spent many months in intimate daily touch with the work in a fabricating yard, states without reserve that "the work is superior to anything ever done in ordinary shipbuilding."

Curved Work Accurate—In some of the cases only the straight part of the ship is fabricated in the bridge shop, while in others molded and curved work also is done away from the yard. The quality of work appears to be independent of the large differences in system between the various yards, whose bridge-shop allotments range from 70 per cent. of the entire hull to 100 per cent.

The amount of altering or scrapping of bridge-shop-fabricated material has been negligible. As described by an experienced steel man now in shipyard work, the material does not contain many more field errors than ordinary viaduct work. One yard reports that during the construction of several ships not a piece was scrapped except for mistakes made in the yard itself.

Effect of Distance—Under present shipbuilding conditions fabrication is done at distances ranging from 5 to 1500 miles from the shipyard, yet there appears to be no effect of distance. Remote fabrication has been fully as successful as that done nearby. One yard had some of its best results, both in quality and deliveries, from the most distant shop of the several which fabricate its material. A concise summary of the effect of distance is found in the remark, "Fabrication at a distance is exactly the same thing as fabrication at the yard, except that the shop is 300 miles from the ways instead of 300 feet."

Distant Fabrication Does Not Complicate Erection—While many difficulties have developed in ship erection in the large fabricating yards during the year, it does not appear that these are chargeable to the system itself. It is, in fact, stated specifically that outside fabrication involves no greater erection difficulties or necessary costs than ordinary shipyard methods. Actual operations during 1918 have been affected by troubles of sequence of material and shortage of skilled labor to an extent that makes the erection performances no criterion of reasonable possibilities.

Conclusions on Cost Not Yet Possible

No present basis exists for comparing the cost of ships built under the outside-fabrication system with those built under ordinary methods. Main factors for comparison are the shop, transportation, handling and erection costs. Under the wholly abnormal cost, labor and urgency conditions of the past year, available figures are valueless for the necessary comparisons.

Concerning transportation costs: Some fabricated-ship contracts, let to shops located near steel mills, were based on fabrication in transit, so that the fabricated material arriving at the shipyard has no higher railway charge than raw steel shipped to the yard direct. In other cases the cost of shipment of steel to the bridge shop and thence to the shipyard has been several dollars per ton above that of direct shipment from mill to yard. It seems likely that under normal conditions the excess transportation charge, if any, would be negligible. Handling charges also should not differ materially.

Shop Costs Probably Favor Bridge Shop—So many factors bear on any comparison made between fabrication in a bridge shop and in a yard shop, that present contract prices throw little light on the matter. The fundamental element is the relative efficiency of the two kinds of plant. The past year's work has afforded opportunity for comparative judgments. Experienced shop managers state as a result of such comparisons that bridge shops are unquestionably able to work more economically than shipyard shops. For their normal production, bridge shops have been developed to a high degree of efficiency under keen competition, while no similar direct influence toward efficiency has been active in the case of shipyard shops. Men who have had occasion to study yard punch shops since the Emergency Fleet Corporation took over control of shipbuilding report that most of the shops could be greatly improved in efficiency by revising their layout, equipment, arrangement and operating systems.

Under present conditions, therefore, it appears probable that bridge-shop fabrication is about on even terms with yard-shop fabrication, taking into account the differences in shop efficiency and in amount of handling. It is assumed that the bridge shop is at the time in a position to do the shipwork without unbalancing its shop program or seriously lowering the load factor on part of its equipment, in view of the fact that shipwork makes use of only part of the equipment of a bridge shop.

The advantage of bridge shops having multiple and other automatic or semi-automatic punches, capable of doing most economical fabrication if the ship design permits their use, has been a factor in the past year's work. Its influence may be modified in future by the introduction in shipyards of multiple punches and semi-automatic punch tables, on an extensive scale.

Difficulties of Sequence in Getting Hull Material Due to Size of Operations

Serious difficulties have beset all the fabricating yards during 1918 with regard to the speed of building ships. These difficulties appear to have resulted partly from labor shortage and partly from irregularity in the receipt of fabricated material—in other words, the impossibility of getting hull material in sequence.

Though in the large yards steel has been piling up in storage since midsummer, yet in general the shipways have always been ahead of the steel supply. This meant not merely delay, but all the lack of system that hand-to-mouth living implies—and this under the worst kind of pressure for speed, the yard men explain. "The impossibility of getting material in sequence has brought a series of misfortunes in its train that no one who speaks plainly will deny," it is said. In part, perhaps, the sequence difficulties arose from the steel shortage, and in part from shop difficulties chargeable to the new character of the work. The abnormal scale on which the operations were conducted was the chief source of trouble, however. No reason has appeared for attributing the lack of sequence to the fabricating system itself. Under normal conditions and with the system worked on a normal scale, the difficulties should vanish.

Modifications of Ship Design

Practically all the fabricating yards have worked with simplified designs of ships. Simplification was thought necessary because of doubt as to whether bridge shops could do shipwork successfully. Allowance for the limitations, actual and fancied, of the existing shop equipment was therefore made by more or less radical simplification of lines and of structural details.

As a result of the past year's experience, many fabricated-ship men are coming to the belief that such simplification is not an indispensable thing with regard to feasibility or quality of work or its cost. Similarly, some of the large yards have virtually concluded that a large part of the templet making should be left to the bridge shop, and that detail drawings carefully developed in the drafting room are a satisfactory basis for fabrication.

Difficulties have arisen in the case of two yards through necessity for distributing their work among a very large number of individual fabricating shops. Uncoördinated deliveries have resulted from the distribution adopted, in a measure. It is now acknowledged that allotment to many fabricating shops offers a difficult problem.

Concentration of fabrication in a few big shops, to each of which large sections of a ship or entire ships could be allotted, has been decided upon in one case. Four inland ship-fabricating shops are being erected by the Emergency Fleet Corporation, of capacity 10,000 tons per month each, for this purpose. These shops will constitute an important basis for future ship-fabrication work.

Fourteen Points Essential to Establishing a Sound Railway Policy

By L. C. Fritch
Vice-President and Chief Engineer, Chicago, Rock Island and Pacific Railway Company, Chicago

1. *Incorporation of Interstate Common Carriers under a Federal Act*
2. *Private Ownership and Operation*
3. *Federal Regulations and Control*
4. *Pooling of Traffic*
5. *Unification and Common Use of Facilities and Equipment*
6. *Regulation of Transportation Rates, Wages and Working Conditions of Employment by Interstate Commerce Commission*
7. *Uniform Accounting and Statistical Methods to be Prescribed by Interstate Commerce Commission*
8. *Federal Guarantee of a "Standard Return" to Meet Fixed Charges, Dividends and Surplus for Improvements*
9. *Representation on Board of Directors of the Federal Government*
10. *Elimination of State Regulation and Control in Interstate Commerce*
11. *Federal Control and Regulation of Capital Issues and Financing*
12. *Valuation of Property by Boards of Arbitration*
13. *Regional Directors to Supervise Operations*
14. *Standardization of Method and Practice in Railway Operation and Management*

Transportation is the most important item of all the various economic problems confronting the nation. In direct proportion to the wise solution of this problem will be our future progress.

The "fourteen points" enumerated above, if intelligently and rationally applied to this question, will solve the problem in the interest of the public, the owners and the employees, the three most vitally interested parties. Any settlement which does not protect these interests equitably and fully will retard national progress and adversely affect the welfare of the people.

1. *Federal Incorporation*—The first essential to enable common carriers to perform their public functions is an allegiance to one master, the Federal Government, which makes necessary incorporation under Federal statutes. Experience has conclusively shown that the 49 regulating bodies existing at the present time have neither the inclination nor the ability to adopt a uniform and rational set of regulations. It is not possible for a corporation or an individual to serve two masters, particularly when each master prescribes conflicting rules, a compliance in one case being an offense in the other. Under such chaotic conditions no satisfactory results can be obtained, and the proper solution can only be found in Federal incorporation.

2. *Private Ownership and Operation*—This is to be preferred to Government assumption of these functions, for the reason that a government has in the majority of instances completely failed to operate any enterprise efficiently, unless it may be a political machine. The nation at this time is not prepared to assume the financial burden which acquisition of ownership of some twenty billions of property would impose upon the people, in addition to the war debt, and if the operation of the railways is placed in the hands of the owners, and proper and sound public regulation is enforced, the results will be more satisfactory than could possibly be secured under Government ownership and operation. Proof of this fact is abundantly available. To be convinced of this truth it is only necessary to investigate the mistakes Canada has made in its railway policy.

3. *Federal Regulation and Control*—These are most essential elements in the proper solution of the future railway policy. The assumption of the control of railways during war time has demonstrated the necessity and wisdom of such action. While many things are done under war emergency measures which, in peace times, would not be necessary, yet the peculiar interests of the owners must be directed and controlled, and this can only be done by the supreme authority of the Government, which should rule for the benefit of the public as a whole and control the selfish purposes of the individual, be it a person or a community. Federal regulation and control will act as a governor to private ownership and operation, but it must be absolutely divorced from all political affiliations.

4. *Traffic Pooling*—The pooling of the traffic of the country among the railways will produce the most economical results and efficient service. It will move the traffic over the shortest and most economical routes, will prevent congestion and insure each carrier a fair proportion of traffic, resulting in a scientific use of the railways in the interests of the best service at the lowest cost. The most pernicious and destructive competition will be thereby eliminated, through cutting out unnecessary and duplicate service, resulting in reduction in cost and improved service otherwise unattainable. The repeal of laws now prohibiting the pooling of traffic is, of course, necessary. In effect, this law has been suspended during Federal control of the railways, with most excellent results. Under future Federal regulations the law should be repealed, if the public is to de-

rive the benefits of the economies already secured in this respect during Federal control. Service will still be the controlling competitive feature, which will be an incentive for efficiency in operation, and the best service at the lowest cost will inevitably result. The weaker lines must be compensated fairly in the division of traffic to enable them to give adequate service to the territories which they traverse. This is not a difficult matter and can be equitably adjusted.

5. *Unification and Common Use*—Federal control of the railroads has accomplished excellent results in the unification of terminals and common use of tracks, equipment and other facilities. Such results were impossible under private control, due to the selfishness of the individual roads, regardless of the benefits such use might be to the public. The duplication of expensive terminals, trackage, equipment, etc., has resulted in capital expenditures of millions which might have been avoided under a sane policy of regulation and common use. There is no field in the operation of railways more fertile of results—economical and beneficial alike to owners of the railways and the public—than the unification of terminal facilities, trackage and equipment and their common use under fair regulation, but it will require the supreme authority of the Government to make it effective and overcome the prejudice of the individual owners, which has been the means of preventing such consummation under private control.

6. *Regulation by Interstate Commerce Commission*—It is eminently unfair to hold that the Interstate Commerce Commission has entirely failed to perform its functions. As a regulating body it has performed eminent service to the public in the prevention of discriminations and favors to certain classes of shippers, and by these very means has performed the valuable service to the carriers in "protecting them against themselves." The carrier retained the revenues which before the days of the Interstate Commerce Commission were largely dissipated in refunds and rebates to favored shippers. The commission, by its regulation of rates, has given the public the lowest cost of transportation of any country in the world, and has thus fully justified itself as a public body. On the other hand, it may be claimed that the result of this extreme policy has reached its limit, and must be reflected in decreased transportation facilities and impaired service, due to the inadequacy of these rates to produce sufficient revenue to enable the carriers to perform their public function properly.

The duties and responsibilities of the commission should be enlarged to cover, not only the income, but the outgo of the carriers as well, to the end that sufficient revenue will be derived to meet the necessary expenditures of fixed charges, reasonable return on investment, operating expenses, and a surplus to provide necessary improvements and extensions. Granted these enlarged duties and powers, the commission will be alike responsible to the public, the owners, and the employees, and it will be in a position to demonstrate its usefulness and, if properly constituted, will amply justify its existence. The commission cannot be held responsible for its inability to secure results which it was powerless to secure under the laws regulating its duties. The proper solution lies in granting it the necessary legal powers to perform its various functions and then in holding it accountable for the results. If thus constituted, it will not be found wanting. The fixing of wages and working conditions of employees engaged in transportation should be controlled by the same body that prescribes the revenues of the carriers. The highly specialized departments of the commission should have charge of these important matters and alike protect the interests of the employees, the public and the owner of and investor in railway securities. Under present conditions, the operating heads of railways devote a large part of their time to negotiations with labor organizations over wage schedules, working conditions and grievances, leaving little time to be devoted to the legitimate duty of running their business. This should be corrected and the matter handled by a competent technical body, skilled in such matters, with time to devote to them and reach equitable conclusions which will be stable and satisfactory to the interests involved.

7. *Uniform Accounting*—The Interstate Commerce Commission has performed a valuable duty in prescribing a uniform system of accounting for common carriers, and while modifications of the existing system are desirable, it has produced greater reliability in operation and more confidence in the carriers, and has in this respect performed a service of inestimable value to both the public and the carriers. In addition to the system of uniform accounting, there should be prescribed by the commission a uniform method of reporting statistics covering the various operations. This is a necessary adjunct to the accounting system to enable the true results of operation to be reflected.

8. *Federal Guarantees*—The Government operation of railways under war-time conditions has been the means of saving from bankruptcy the majority of the companies taken over. It would have been impossible for many of these companies to pay the high costs of wages and material entering into operations during the war, and meet their financial obligations. The Government has performed a great public service in thus protecting the roads against the calamity which confronted them, and its duty will be fully met if the roads are retained under Government control until the proper adjustments in economic conditions have been made to enable them to carry their own burdens. A return of the roads to private control before that time would be a public calamity.

Under Federal control, the law provides that the carrier shall receive as compensation a "standard return" equal to the average annual operating income during the three years which ended June 30, 1917. In the case of the strong roads, this amount is generally sufficient to meet fixed charges, a reasonable dividend, and a surplus to finance necessary improvements and extensions. In the case of the weaker roads, however, this standard return is not sufficient to meet financial obligations. Some of the so-called "weaker" lines have made requests for additional compensation which have good and reasonable grounds for consideration, and in the interests of the public should be allowed, to enable these roads to discharge their financial obligations. It would be disastrous to have a number of these roads default in their payments at this time, and the Government owes it as a public duty to the communities served by these lines that they shall remain solvent corporations.

The proper policy to protect the transportation industry must make provision for the so-called "weaker" roads; they serve various communities which depend upon them for their existence. It is a Governmental duty to preserve these properties and aid them in such a manner as will enable them to exist and perform their functions properly. This can be done by guaranteeing a standard return to such companies sufficient to enable them to meet their financial obligations, paying the operating expenses, fixed charges, a reasonable return on the investment, and expenditures for improvements and extensions, all to be done under full Government regulation and control. The stronger lines might by an equitable plan assist the Government in meeting such obligations.

9. Government Directors—Government regulation and control makes necessary a voice in the management of the properties, and to this end adequate representations on the boards of directors is essential. The policy of selecting able representative business men to act for the Government in such capacity would result in business management of the railways in the interests of the public and would have a wholesome effect in railway administration.

10. No State Regulation of Interstate Matters—The regulation of common carriers by the various state commissions has resulted in confusion and increased cost of transportation, without any direct benefit to the public. There are certain functions which must be regulated by the communities, such as police powers, health regulation and questions of purely local character. These should be delegated to municipal and state authorities, but the broader powers, which affect interstate commerce, should be regulated by the Federal Government alone. At present there are 49 regulating bodies having jurisdiction over railway operation, and in no two states are the regulations the same. Indeed, the rules in some states conflict with those of an adjoining state, and in many instances what may be required in one state may be strictly prohibited in another. This could be regulated in a uniform manner by one authority—the Federal Government—with equal justice to all. There is scarcely a state-made rate which does not affect interstate rates—therefore it is the function of the Government to regulate interstate commerce without discrimination or favor to any community or person. This cannot be accomplished under state regulation. The first essential, therefore, to a uniform policy of Government regulation and control is to abolish state regulation and concentrate this power in the Federal Government, for the benefit of the whole people.

11. Federal Control of Financing—There may have been cases of flagrant violation of the rules of propriety in the issuance of railway securities in the past. There is no defense for such action and no apology can be made for it, but, because isolated cases have existed in the past, and because a limited amount may have been irregularly issued, is it fair to condemn the entire railway security issues? The proper solution of this problem is so to regulate railway financing and capital issues in the future that it will be impossible to continue the abuses of the past. This would restore public confidence in such investments and enable the roads to secure capital for improvements and extensions.

12. Valuation by Arbitration—The proper Government regulation and control of common carriers makes necessary a consideration of the value of the respective properties. It may be desirable to consolidate certain properties or operate them in common, which calls for data as to the value of the properties involved. The physical valuation of the railways being made by the Interstate Commerce Commission is promised in 1920 or 1921. This may, in many cases, be too late for the purpose of carrying out a general railway policy. Much doubt is expressed by railway owners as to the valuation which the commission will finally place on their property. This will result in lengthy litigation, to which the roads will resort, unless an agreement is reached. It would seem more desirable to submit the question of valuation to impartial boards of arbitration, which would reach results more quickly and with justice to all concerned.

13. Regional Operating Directors—Numerous suggestions have been made to apply the experience gained in the organization of the Federal reserve banking system to the regional control of railways. Seven regions have been created, each in charge of a regional director. The objection to this system is that it results in a centralized control, from which authority must be obtained governing the details of operation. Such a system will not produce the most efficient results, as it takes away from the direct operating heads of the various properties the initiative resultant from complete authority over the details of operation.

A system of regional boards of governors similar to those in the Federal reserve banking system would produce better results than the present scheme of centralized control over operations. The boards should act in an advisory and supervisory capacity only, leaving the details of operation and responsibility in the hands of the active managers of the respective properties.

The transportation business requires prompt action and will not brook the delay incident to appealing for authority to a central source, except in matters of policy. The man on the ground should have the authority to act on his own responsibility. With it he will secure results.

14. Standardization—Transportation is of a similar nature all over the country, and while the conditions under which the operations are conducted vary in different sections there are numerous and various practices and methods followed to obtain the same results within the same territory.

There is one method of obtaining a certain result which is better than every other plan, and on almost any railway system there are certain methods and practices used to obtain certain results, which methods and practices are better than those used on other roads. Experiments are costly, and much time, money and energy are needlessly expended. This could be avoided by utilizing the experience of others.

A committee or committees on the standardization of methods and practices in railway operation and management could save millions of dollars annually in the operation of our railroads, if the standards formulated were put into practical effect. These results can be secured through the means of regional boards having broad powers over the railways, all working to a common purpose, "The best service at minimum cost."

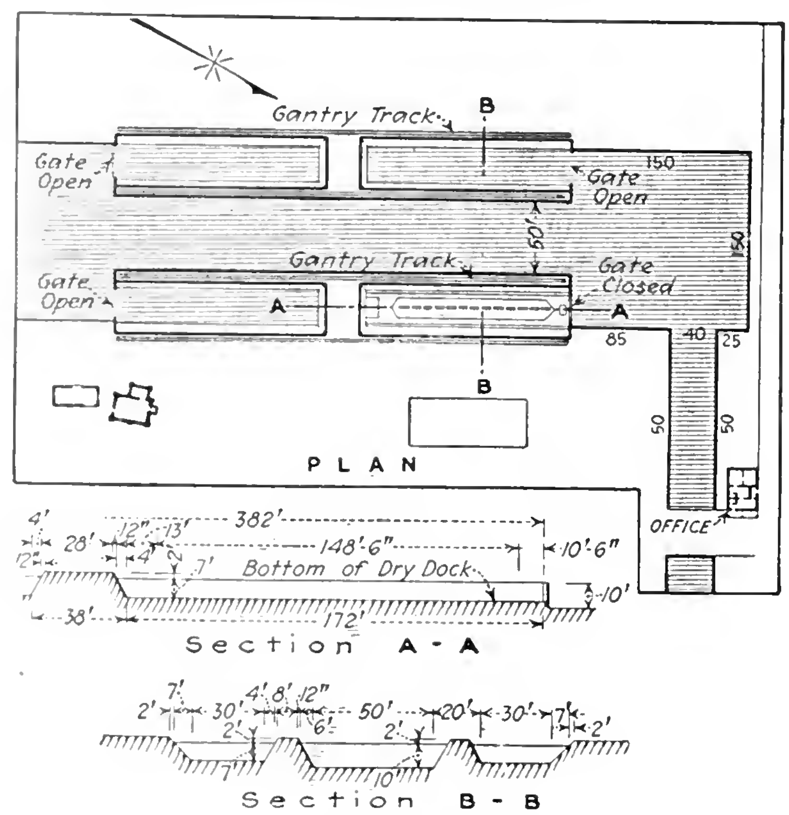
Build Boats in Dry Docks at New Yard in Detroit

Concrete Barges Under Construction on Concrete Floors Inside Dikes Which Will Be Flooded for Launching—Lighters Carry Construction Machinery Alongside Dry Docks

CONCRETE barges for the New York State Barge Canal are being built at the new yard of the Grayhaven Shipbuilding Co., on the Detroit River, Detroit, Mich., in a yard which contains many original features, the most important of which is the use of dry docks in which to build the barges. There are at least two building docks in this country for large ships, but the design of an entire shipyard around a series of dry docks is entirely new, so far as the records show. The yard is intended to be a permanent undertaking, though at present it is being devoted entirely to the construction of five concrete barges for the United States Railroad Administration.

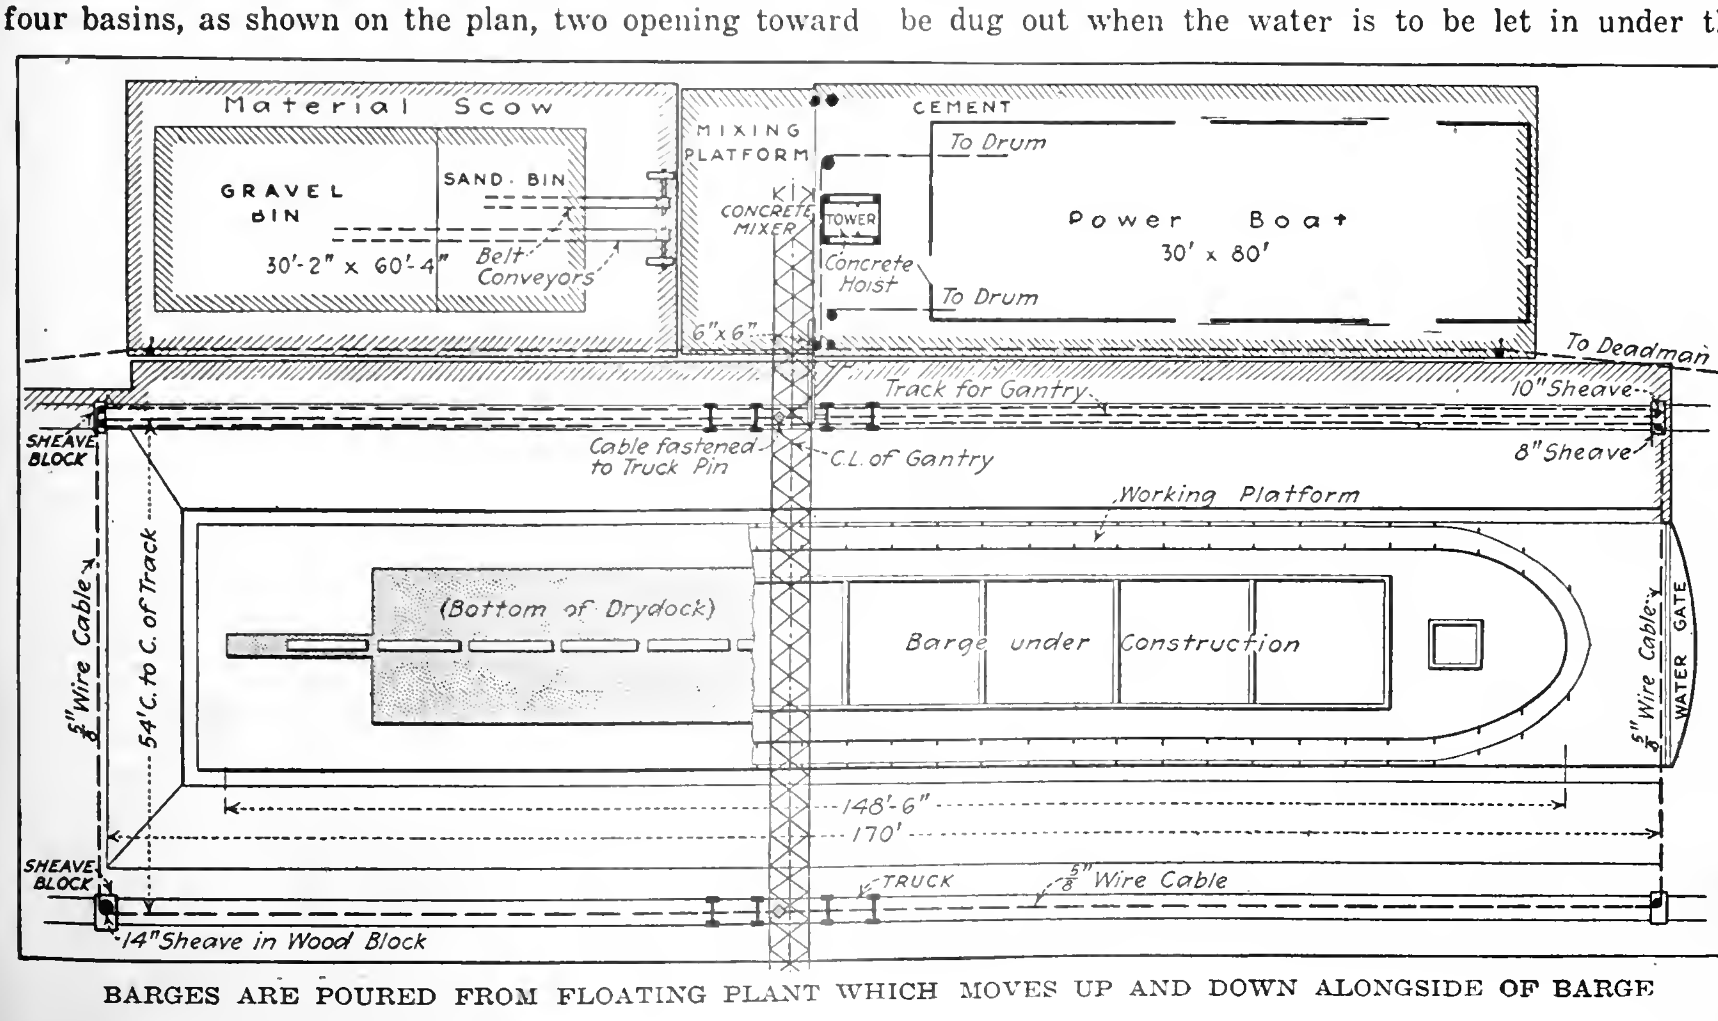
The site of the yard was a real-estate development, the main feature of which was a lagoon 150 ft. wide extending up from the Detroit River, which is about 2000 ft. away. This lagoon was connected by a cross canal to a similar lagoon also extending to the river, it being the intention to sell building lots with water frontage on the whole site. No houses had been built at the time it was taken over last July. The dry docks of the new yard have been built out into the lagoon, and the waters of the lagoon will be used not only to float the completed barges out to the river, but also to carry lighters and barges bearing the construction material and plant. Connection is also established over a bridge across the connecting canal between the lagoons, so that the yard may be reached by trucks and wagons.

The first step toward constructing the dry docks was to throw up a continuous dike about 382 ft. long at a distance of some 50 ft. from the shore of each lagoon, and then to cut in two the basin so formed on each side, with a cross dike extending to the shore. This formed four basins, as shown on the plan, two opening toward the shore and two toward the river. The bottom of each basin was then paved with a 5-in. thickness of concrete; the side slopes of the dikes were smoothed off but left unpaved, and gates were placed across the opening of each of the basins. Four dry docks were thus formed,

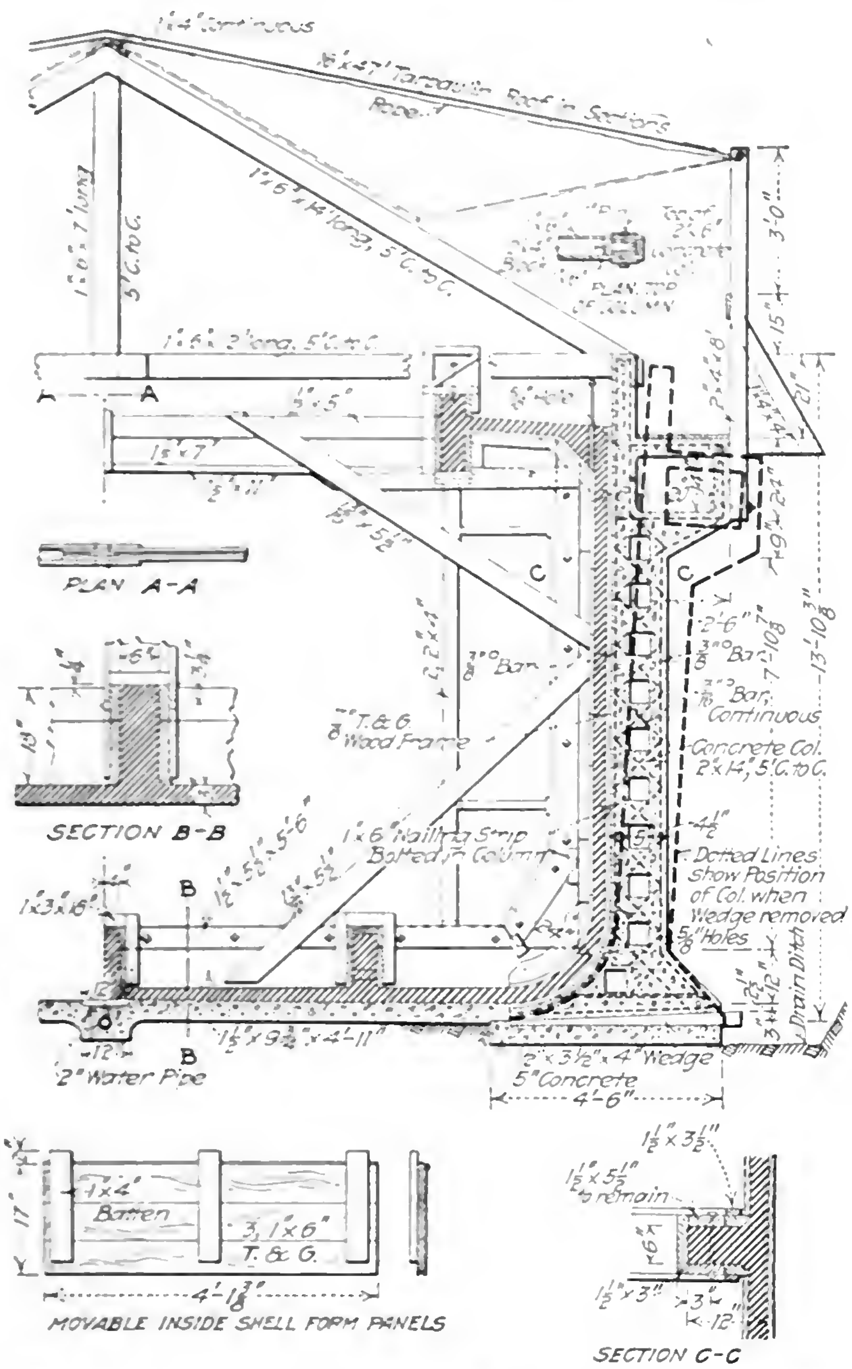


FOUR DRY DOCKS ON LAGOON MAKING IN FROM DETROIT RIVER ARE WAYS FOR BARGES

having a depth of 7 ft., a total inside bottom length of 172 ft., and a bottom width of 30 ft. The main lagoon was then dredged to a depth of 10 ft. For the time being the gates consist merely of earth dikes which will be dug out when the water is to be let in under the



BARGES ARE POURED FROM FLOATING PLANT WHICH MOVES UP AND DOWN ALONGSIDE OF BARGE



CROSS SECTION SHOWING FORM DETAILS IN BUILDING CONCRETE BARGE

boats to be launched, but it is intended to have permanent gates, of stop logs, which can be readily removed and replaced.

The concrete barges now being built in the yard were described in *Engineering News-Record* of Aug. 8, 1918, p. 271. Each boat is 150 ft. long, of 21-ft. beam, and 12 ft. deep. It is of simple type, with frames 5 ft. on centers, a 3-in. shell and an open hatchway crossed with deck beams every 15 ft. The bottom is flat, except for a 2-ft. quadrant curve at the bilge, but both bow and stern have framed lines.

Many innovations have been introduced in the construction of the barges. The principal points of interest are the use of precast concrete frames to carry the outside forms, a hydraulic pump device to give the completed barge an initial lift so that water can get under it for launching, the gantry crane control for the ways, and the use of floating equipment for the concrete mixing and placing.

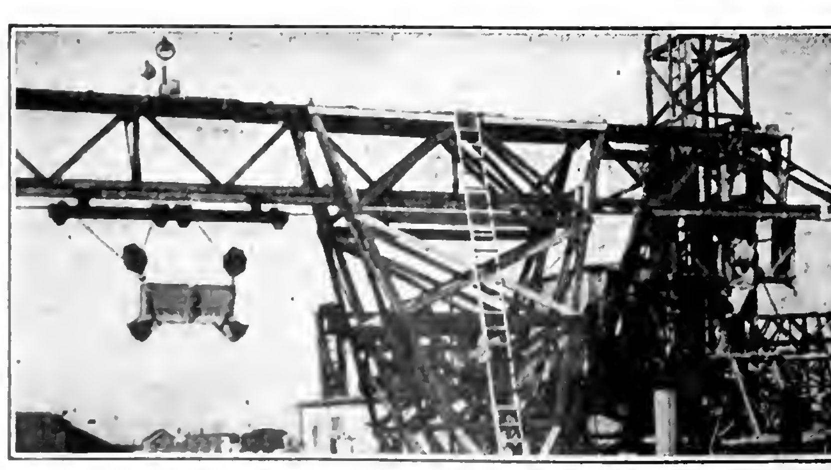
As shown in one of the drawings, the outside forms of the straight section of the barge, which compose the greater portion of its length, are made up of tongue-and-groove lagging which spans concrete jack columns spaced 5 ft. center to center and fastened with removable hooks to eyes let into the depressed concrete floor running along the outer edge of the dock. These jack frames are of precast concrete, with openings to save weight and also to provide spaces for trestle beams. They are 2 x 14 in. in normal cross-section, and are reinforced with $\frac{3}{8}$- and $\frac{3}{16}$-in. steel, as shown. Each frame has an extension at the top to carry the working platform, and has also a sloping bottom which is wedged up from the dock base. The outside forms—that is, the tongue-and-groove lagging—are carried as a continuous section for the entire straight length of the barge, about 120 ft.

This lagging is tacked to a 4-in. wood strip held to the concrete frame by bolts through holes left there for that purpose. Spaced on 1 ft. 8 in. centers between the frames are vertical intermediate 2 x 4's, supported directly on the dock bottom and intended to give additional bracing to the outside forms. The outside form of the bilge curve is made up of small slats laid longitudinally and coming flush at the lower end with the top of the concrete floor of the dock. The bottom of the barge is poured directly on this concrete base, which is oiled or soaped to insure easy removal after the concrete has set.

The outside jack frames also carry at their top a light truss which serves the double purpose of cross-bracing the frames and of carrying the inside forms. From the outside of the working platform there rise posts which carry, with the aid of the center post of the cross-truss, the tarpaulin roof which must be ready, according to the specifications, in case of wet or extra cold weather during the continuous pouring of the barge.

The outside forms between the beginning of the end curves are removed as one piece by the knocking out of the wedges under the jack frames. Thereby each frame is let drop 2 in. at its outer support, which means about 7 in. away from the concrete at the top of the shell. Once away from the shell, the whole side form is slid back along the concrete floor of the dock, until it is well out of the way. When a new barge is built the whole thing is wedged up again and pushed into proper position.

The end forms for the barge are of mortar molds. The stern, which is of somewhat complicated curvature, is in three sections divided along vertical lines. These three sections were set up in a shop with the frames

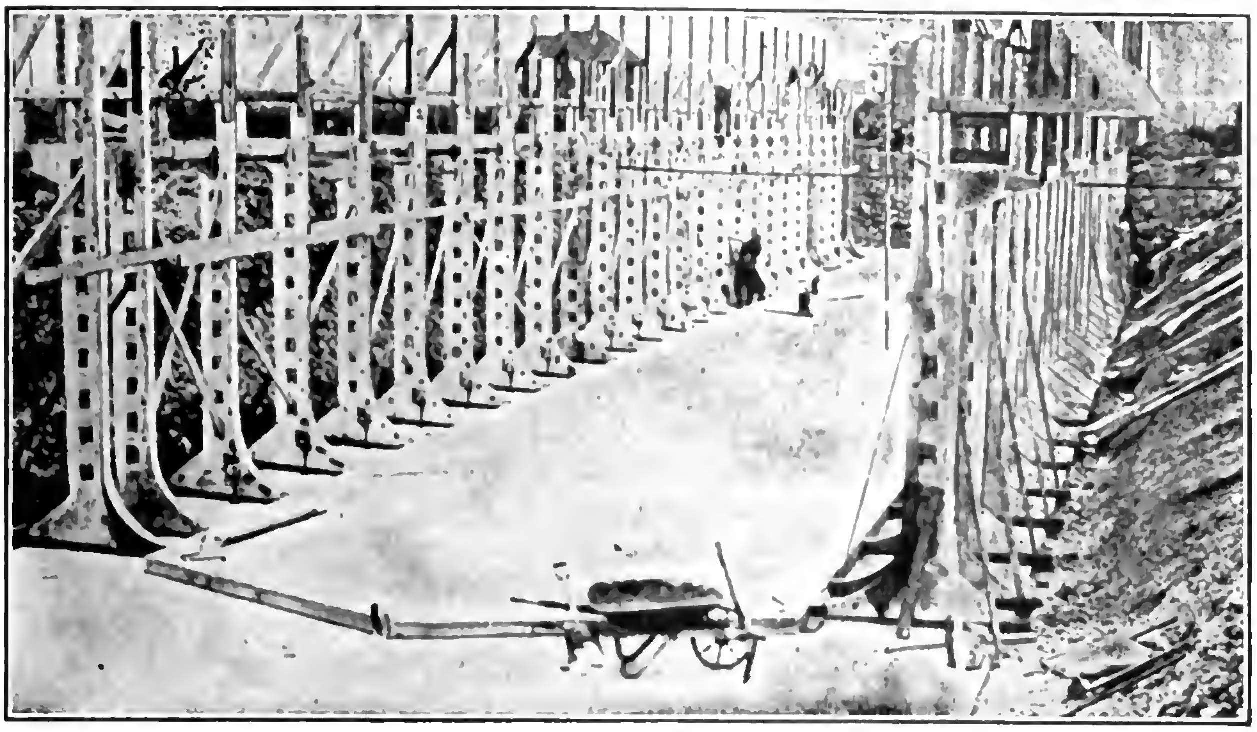


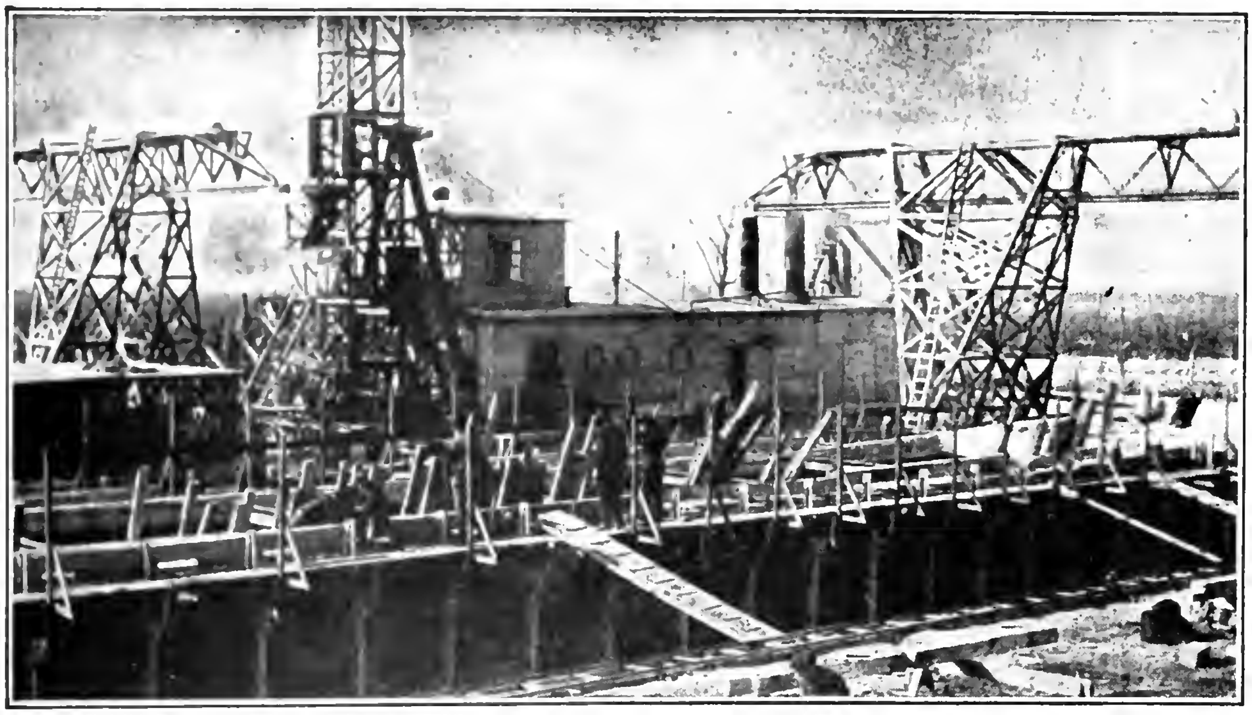
TWO-ENDED BUCKET DEPOSITS CONCRETE IN BOXES INSIDE BARGE

of timber cut to templets and a sheeting of wire mesh tacked to the proper curvature in each section. An interior and an exterior layer of mortar were then plastered onto the metal, forming a perfect mold for the curve. These forms were then blocked up on the con-

crete bottom of the dock and slid into proper place. When the section is cast they are dropped with wedges and slid out in three sections. The bow has a one-way curvature above the bilge curve, and this upper section was formed with the regular ⅞-in. tongue-and-groove material bent around wooden frames cut by templet to proper curve. Below the bilge curve, where there is double curvature, due to the turn of the stern and of the bilge, a mortar form similar to that employed at the stern was used.

The inside forms are thoroughly cross-braced, but are supported by small concrete pieces blocked up on the steel of the floor. The floor has no top form, of course, a proper thickness being screeded off level. The floor frames—that is, the keelsons and the cross-frames—are in boxes between the keelsons and the frames, and the connecting joints are nailed to the keelson box and screwed to the frame box, so that in dismantling wood screws can be readily taken out and the whole box slipped out. The forms for the side frames are heavy 1½-in. timbers held in place by cross-bracing attached to the bottom frame and to the hatch girders. The design of the barge calls for a wooden strip alongside of each frame, to be used as a nailing strip for the wooden sheathing of the barge. In the design of the forms for the Detroit yard the frame forms are in two pieces—the outer piece, 1½ x 5½ in. in section, being bolted clear through and left in place as the nailing strip for the sheathing. The inner piece, which is 1½ x 3½ in., forms a piece of the inside shell form and is removed when forms are dismantled.





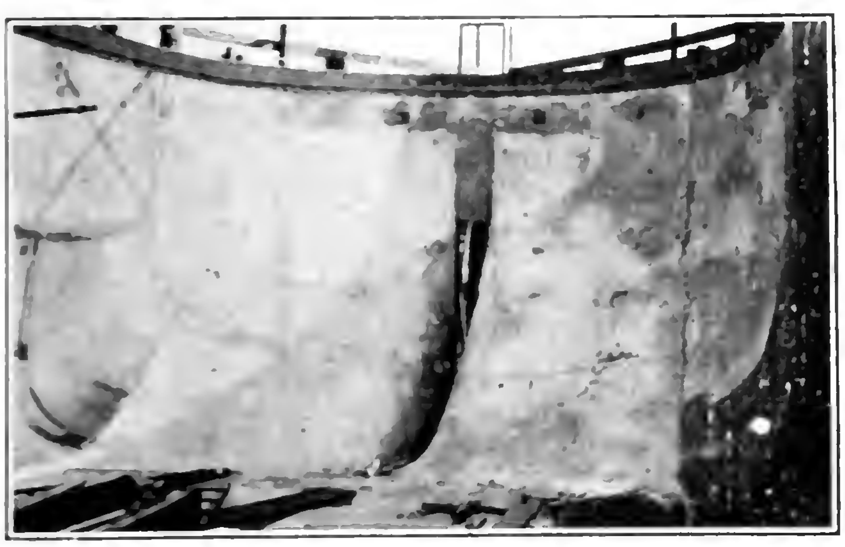
CONCRETE JACK FRAMES ARE FIRST SET UP ON CONCRETE FLOOR OF DOCK TO CARRY FORMS FOR CONCRETE BARGES — WOODEN GANTRY CRANES RUN OVER BARGES UNDER CONSTRUCTION AND DEPOSIT CONCRETE FROM ADJOINING FLOATING PLANT

Provision is made for concreting each of the barges from a dump bucket carried on a gantry crane traveling up and down over the barge. As shown on the drawings, on the top of each dike there is a 2-ft. industrial track. Traveling on this track, continuous along both docks on the same side of the central lagoon, is a timber gantry crane, one for each side of the lagoon. One of the views gives an idea of the appearance of this crane. It has an extending cantilever arm which reaches out over the water side of the dock. When the barge is to be poured the floating mixer plant, consisting of a power boat and a material scow, is brought immediately alongside of the dry dock and is fastened to the outside truck of the gantry crane by a heavy timber frame, so that any movement of the boat parallel to the dock communicates a similar movement to the gantry crane. In order to insure the parallel motion of the crane during any such movement, there is a continuous ⅝-in. cable running along the center of each track and around sheaves across the end of the dock. By the same mechanical motion which controls the well known drafting machine devices, the crane is thus kept moving parallel up and down the track over the barge whenever the material boats are moved up and down alongside of the dock, by hauling on lines to dead men at either end of the floating equipment.

In concreting, then, the operation is as follows: The

material scow, which is a wooden scow with bins let down into the deck, and has belt conveyors running under these bins to the end of the scow, is first filled with enough material to make the run and is lashed tight to the power boat. This, besides carrying the heavy engine equipment for all removing and mixing operations, has an apron with the concrete mixer extending out toward the material scow. Just inside the mixer is a concrete tower with an elevator bucket taking material from the mixer. The mixer and material scows are then fastened alongside of the dock with the gantry crane so that its traveling cross buckets can run on the extended arm directly under the spout of the elevated hopper. Material is fed to the mixer through the belt conveyor, and is mixed and carried up to be dumped into a double-mouth bucket which traverses the beam of the gantry and, controlled by the engineman on the power boat, is lowered into the barge.

Concreting is carried on from two ends of the boat simultaneously. After enough concrete has been dumped

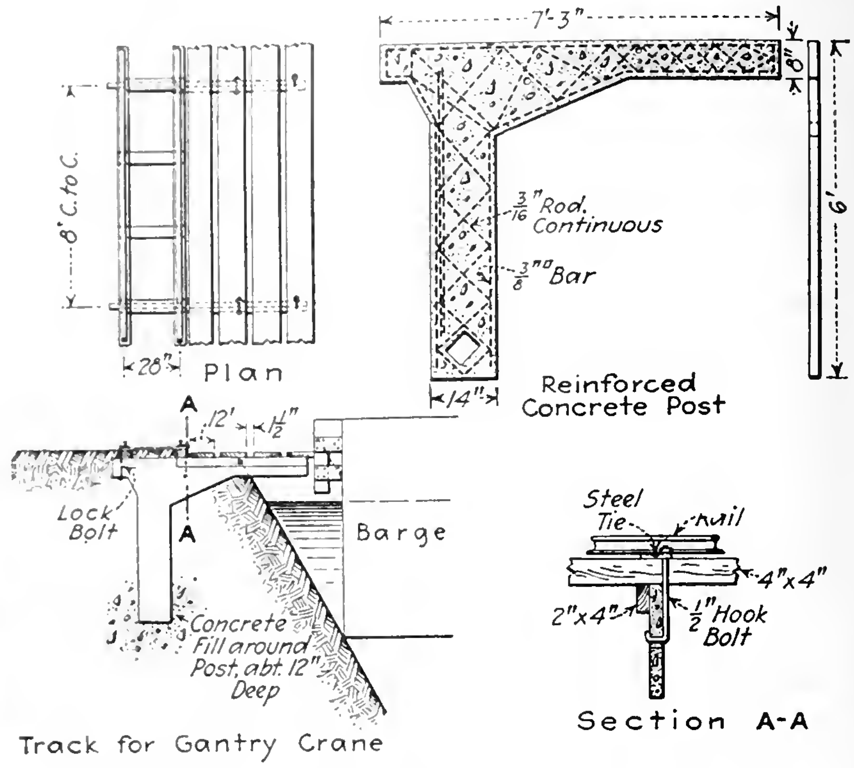


MORTAR MOLD FOR STERN FRAME IS IN THREE PIECES

BASE OF BOW FORM IS MORTAR MOLD

in the boxes at one end of the boat to keep the placers busy, the whole equipment—that is, the scow, the power boat and the gantry—is moved back to the other end of the boat, and the concrete is deposited there. Mixing the concrete and getting it to the boat are not the controlling operations in concreting a barge. The prime difficulty lies in getting the concrete into the narrow forms so that there is ample opportunity for the moving operations, without delaying the placing at either end of the boat.

An interesting detail in connection with the gantry crane is the small precast concrete frames which carry the track for the crane on the dike side. On the inside, it will be noticed, the tracks are on the original ground and do not require additional support, but over



GANTRY TRACKS ARE SUPPORTED ON PRECAST CONCRETE POSTS

the dike it was thought better to provide some extra base.

This has been taken care of by the use of inverted L concrete frames 14 in. wide in the shaft and 2 in. thick, with an extending arm carrying the wooden plank runway which extends out to the concreting barges. These frames are footed in concrete piled around the base and are spaced 8 ft. on centers. They carry longitudinal 4 x 4's on which the steel ties rest.

The final novel device is the lifting arrangement of the barge. It will be seen from the cross-section that the only buoyancy the completed barge will get when the water is let in is the lift under the bilge curve. This is not sufficient to float the boat. There is, therefore, provided along the center line a groove 2 x 12 in. in dimensions in which are set wood planks 9 ft. long, with slot spaces between. Under this groove is a continuous pipe with ¾-in. nipples rising up under the plank every 10 feet.

When the boat is to be launched water pressure is put on this pipe, which lifts the plank, and thereby raises the barge a sufficient height to allow the water to run under the barge and give flotation to the vessel.

The Grayhaven Shipbuilding Co., which built this novel yard and has the contract for the five New York State canal barges, has for its principal members Thomas E. Currie, a well known Detroit concrete contractor, and Edward Gray, engineer. Mr. Gray has recently been connected with the Ford Motor Co. in the capacity of construction engineer.

Other details of the concreting operations at the plant will appear in an early article which will compare the methods in use at four yards building the New York Canal barge.

Routing of Fabricated Ship Material at Bristol

Hull Construction Operated on Basis of Shop-to-Storage-to-Ship System Requires Accurate Timing of Material Supply, Shop Work, and Assembly—Routing Handled by Production Department

MAINTAINING coördination of material supply and shipbuilding, which has proved to be one of the key problems in high-speed shipyard work, is effected at the Bristol, Penn., yard of the Merchant Shipbuilding Corporation by a storage and routing system worked out to suit the plant operation. It is administered by a production department, separate from the technical and operating branches of the yard organization. The machinery of the system is simple, but it works effectively.

With material fabricated in distant shops, it has been found impossible to assure precise sequence of delivery at the yard. Incoming fabricated ship parts cannot be sent directly to the shipways, and therefore coördination of supply and consumption must be obtained by storage intermediate between shop and ship. The advantages of working through storage are so marked, moreover, that this system is applied at Bristol to the entire operation of the yard, including the punch shop and the steam engineering and equipment departments. In other words, the shop-to-ship system favored in the conventional yard practice of former days is eliminated throughout, just as it has been eliminated in all shipyards during the past two years so far as miscellaneous ship equipment is concerned.

Large storage yards for hull material, and storehouses for machinery and equipment, have been provided at Bristol to act as equalizing reservoirs. These, with a system of ordering, routing and handling between shop storage and ways, control the flow of material. The system as used for hull material is described herein, but substantially the same procedure is applied to the other parts of the yard work, as the handling of machinery, rigging and equipment.

Special pre-assembly facilities and space for finished storage have been found necessary to the best working of the Bristol yard. They aid in placing all operations preceding the hull erection upon a manufacturing basis in which the several units can work without mutual interference and delay.

Functional Conditions—Half a dozen different classes of material involved in the shipbuilding work had to be provided for in the operating system.

1. Fabricated material arrives from distant bridge shops, ten or more in number. These shops punch, scarf, countersink—and, to a certain limited extent, assemble and rivet—about 83% of the tonnage of the hull. Much of this material is ready for erection, but some must undergo further working in the yard shop. None of the material can go direct to the shipways, as it does not arrive at the exact moment when it is required and as the incoming cars contain material for several different ships. Therefore it must be delivered to storage—for unloading, sorting and marking with the proper erection marks—and piled where it will be instantly available.

2. Bridge-shop material requiring further work in the yard shop includes such parts as shell plates for the molded body, which must be rolled, and floor frames for placing forward and aft of the middle body, which require the shaping and riveting on of bent bottom angles. This material, drawn from main storage as the shop routine requires, must return to storage after final fabrication, as the work in the shop does not coordinate with that on the building berths.

3. A large amount of raw steel is required for the yard fabricating shop. This is stored close to the shop, and kept apart from storage for fabricated material.

4. Most of the yard shop production is made from templets, and is fabricated on stock so that erection need never be held up by shop delays. When fabricated, the material is in the same relation to the yard as incoming bridge-shop material, and, like the latter, goes to the main storage.

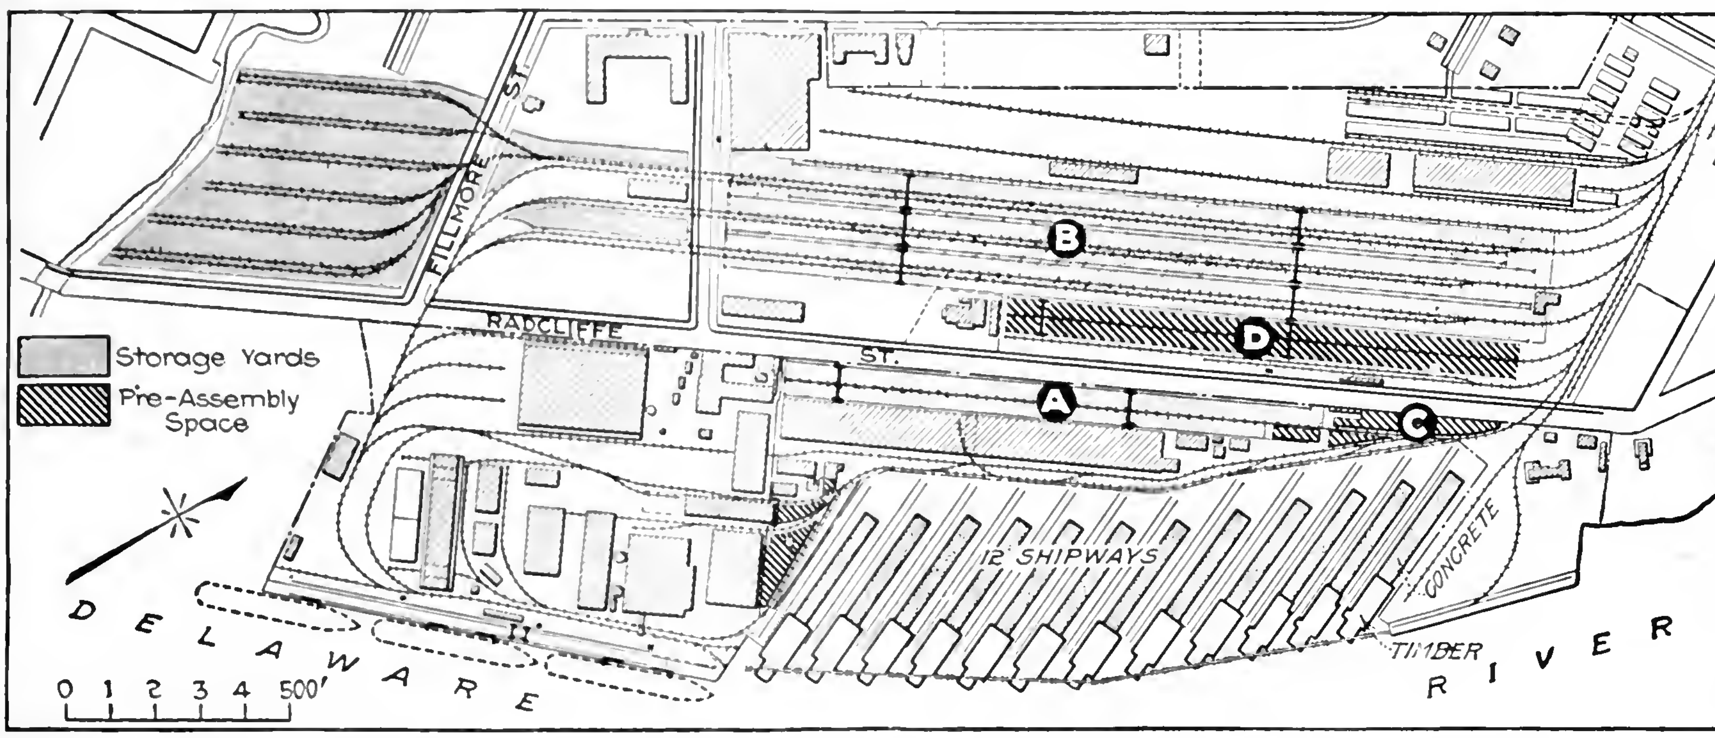


FIG. 1. LOCATION OF STORAGE AND ASSEMBLY FOR HULL MATERIAL AT MERCHANT YARD

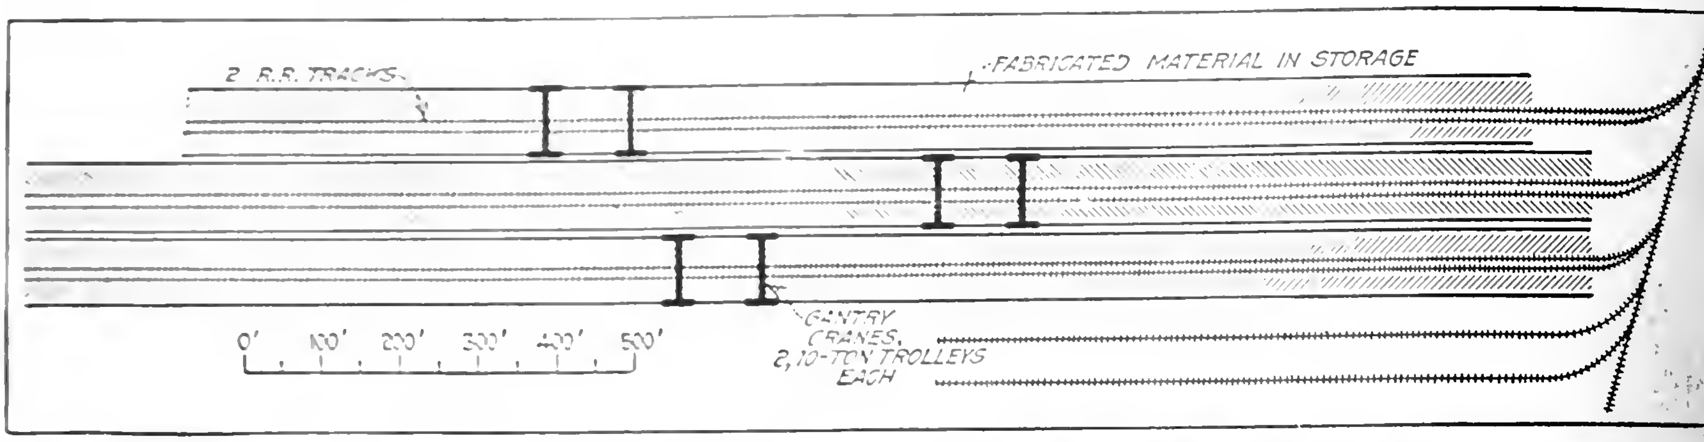

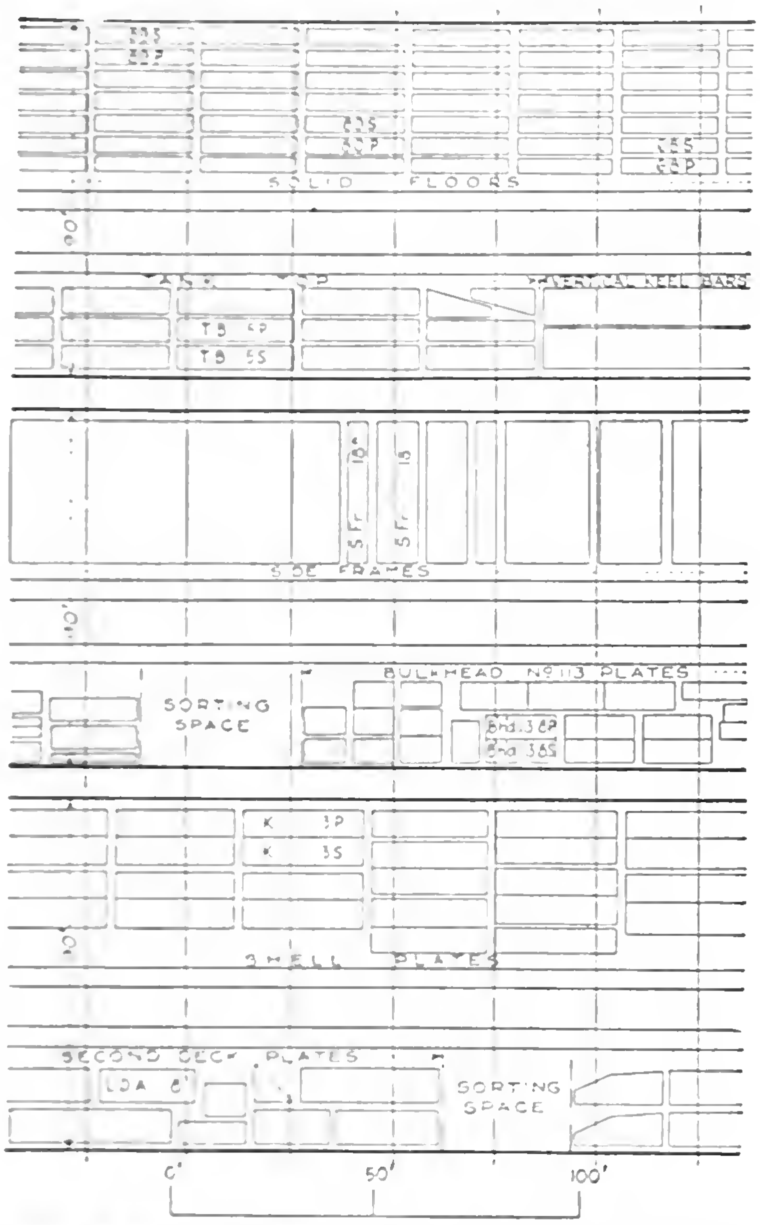

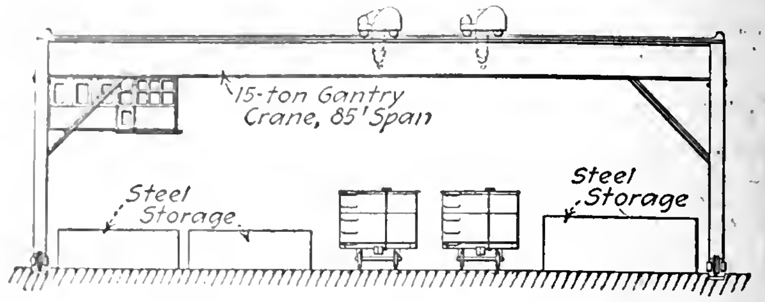

FIG. 2. CROSS-SECTION AND PART PLAN OF STORAGE FOR FABRICATED STEEL

5. A certain number of parts must be "lifted" from the ship. These, of course, require to be put through the shop without delay when the berth requires them. Storage is not involved.

6. Pre-assembly of fabricated material has undergone very great development at Bristol during the past year. It now includes possibly 25% of the total weight of the hull. Assembly of parts such as web frames, floors, stringers, girders, etc., has been carried on from the beginning, but in the expansion of the work deck houses and bulkheads were assembled complete, and assembly has been applied to the entire keel, the fantail, and some special groups such as the bow section of the keel with its frame. The material to be assembled must be drawn from storage, in order to keep the assembly work independent of the shop routine. The smaller assembled parts return to storage, while the larger units are held in the assembly space until needed by the ship.

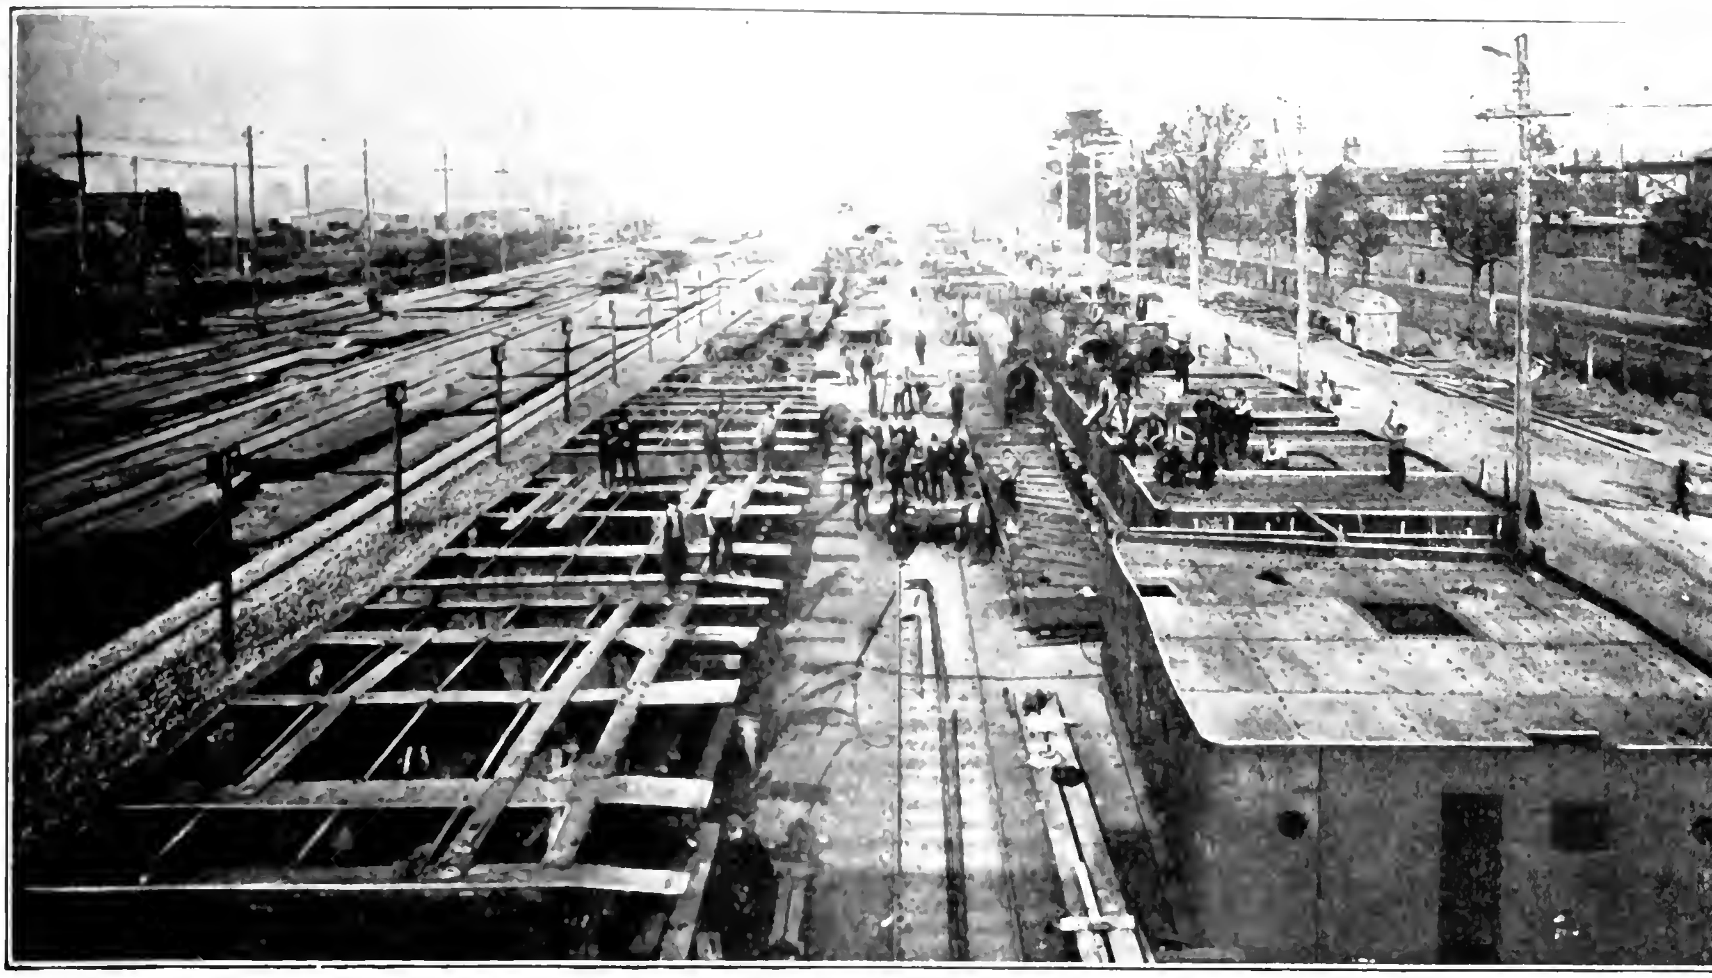
Storage and Assembly Yards—The main elements of the storage system are a raw-material yard directly adjacent to the plate and angle shop, and a large main storage yard for fabricated material. The latter has recently been extended southward, and a section for storage of pre-assembled parts thereby provided. The two main yards are located as indicated by the letters A and B in the sketch plan, Fig. 1. In each, material is handled by traveling gantry cranes, and the yards are therefore arranged as narrow, long bays corresponding to the craneways, 95 ft. wide. The raw-material storage consists of a single bay, while the fabricated-material storage has three bays side by side. Two railway tracks extend down the middle of each bay.

Flat piling is used in the main storage yard. The arrangement of this yard is indicated by the section and part plan, Fig. 2. A separate piling space is allotted to each special piece in the ship; these spaces measure about 20 ft. along the bay and 30 ft. transversely. The storage for assembled material, at the south end, is arranged like that in the northerly part of the yard.

Timber sills laid on the ground are the foundation for the piles of steel. In the plate portion of the yard a few racks have been set up, but in general the rack system was distinctly discarded when the yard was planned. The raw-steel yard is arranged in the same way.

A governing feature in the arrangement of the piling sections in the main yard was the erection schedule of the ship, which fixes the sequence in which the pieces are erected. The piling sections, beginning at one end of the yard, were arranged approximately in accordance with this erection schedule, so that picking up pieces and sending them to the shipway could be done as nearly as possible by a slow, progressive movement of the crane along the length of the yard during the shipbuilding period. The six cranes of the three storage-yard bays correspond to the 12 shipways, with two ways at the same stage of erection.

An important element in the working system is a space for working storage at the head of each shipway. This space is about 50 ft. square, and racks and sills have been placed in it. Originally, the intention was to do some pre-assembly work in this space; parts delivered from storage to the ship were to be stowed under the crane trestles between the shipways. But stowage



MAIN PRE-ASSEMBLY YARD AT BRISTOL IS COVERED BY GANTRY AND SERVED BY TWO RAILWAY TRACKS

under the trestles has been found less convenient than using the head of the way for the purpose.

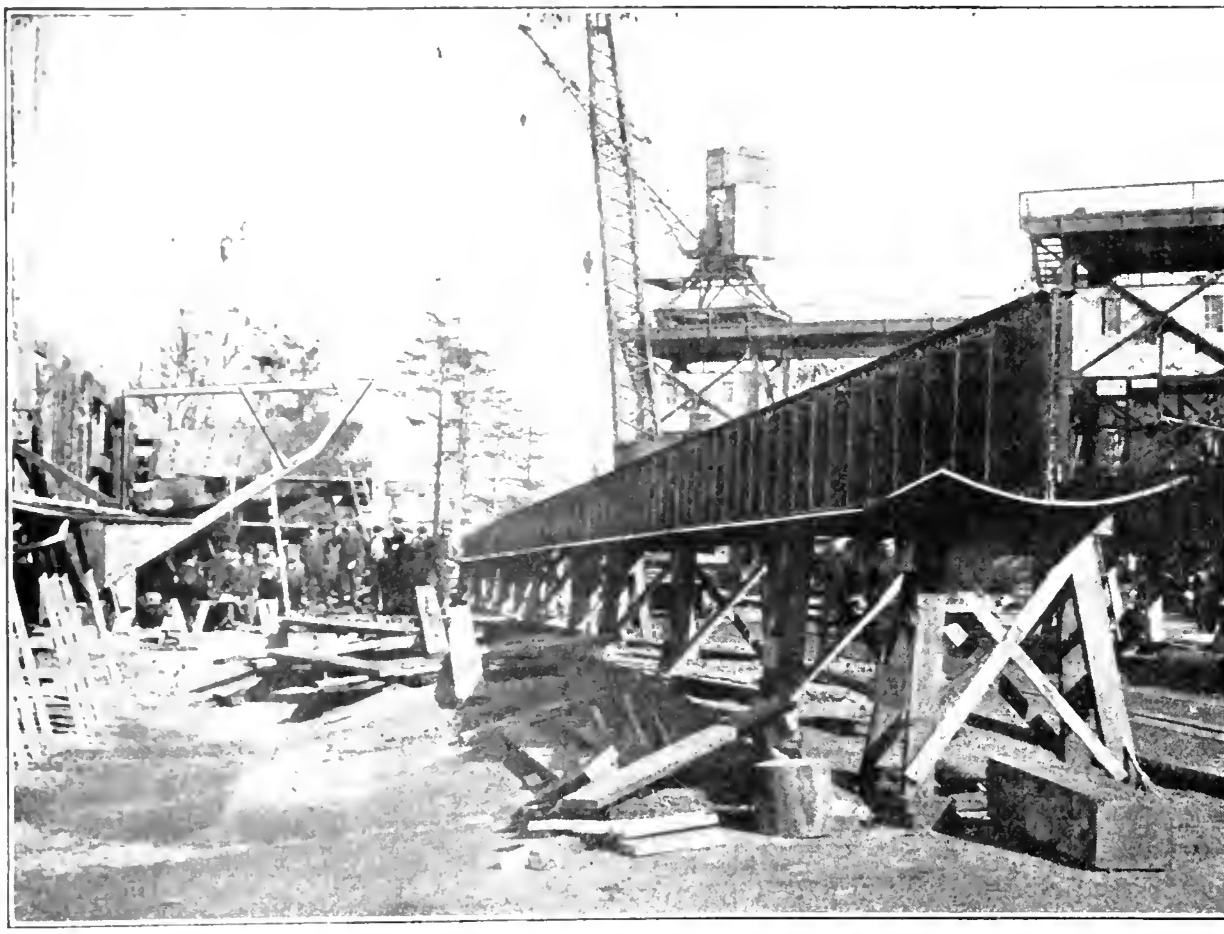
Assembly work was at first provided for by turning over to it a triangular space north of the raw-steel storage, marked C in the sketch plan, Fig. 1. Subsequently it was found necessary to turn over to this work a large area forming the continuation of one of the bays in the main storage yard, as marked by the letter D in the plan. A view of this space is shown by Fig. 4. Crane service is provided by a gantry like those of the storage yard. Compressed-air outlets are arranged along the sides of the supply tracks along the middle of the bay. Assembly of small parts is facilitated by the provision of two Hanna compression riveters under a shelter roof near mid-length of the yard. Other assembly riveting is performed by air hammers.

Deck-houses and bulkheads are assembled entire. The most distinctive novelty of pre-assembly at Bristol is the riveting up of keelson and flat keel plates in continuous lengths of 70 to 100 ft., these lengths further being fitted together and the splices reamed before the sections are taken to the shipway. This is done in the assembly space marked C.

Here also the bow section of the ship is assembled with eleven pairs of frames to form one erection piece.

Erection Schedule Governs—Planning the sequence and timing of all parts of the work, on the shipways and in the shop, was governed by an erection schedule to which the berth work is required to conform. The schedule was made out early during the past year, in conference between the different departments concerned. Thereafter all orders for the bridge shops were timed correspondingly, the storage yard was laid out in the erection sequence, and all work in the shops and on the berths was made subject to the same schedule. A small part of the schedule diagram is reproduced in Fig. 5.

As this diagram indicates, the units of the schedule



FULL-LENGTH KEELSON AND FLAT KEEL ASSEMBLED ON HORSES

are not individual pieces, but "erection groups." These are lots of material equivalent to approximately a carload each, required at substantially the same time. These erection groups are the items by which the shipway places orders for steel with the storage yard.

Adjoining each shipway is a production clerk's office. Here is kept on file a complete set of Material Order sheets (Fig. 2), covering the successive erection groups

rection groups in the entire hull, the average amount f material per group is about 40 tons, representing ather more than a day's consumption.

When the clerk issues an order to the storage deartment, the latter fills the order as detailed on the

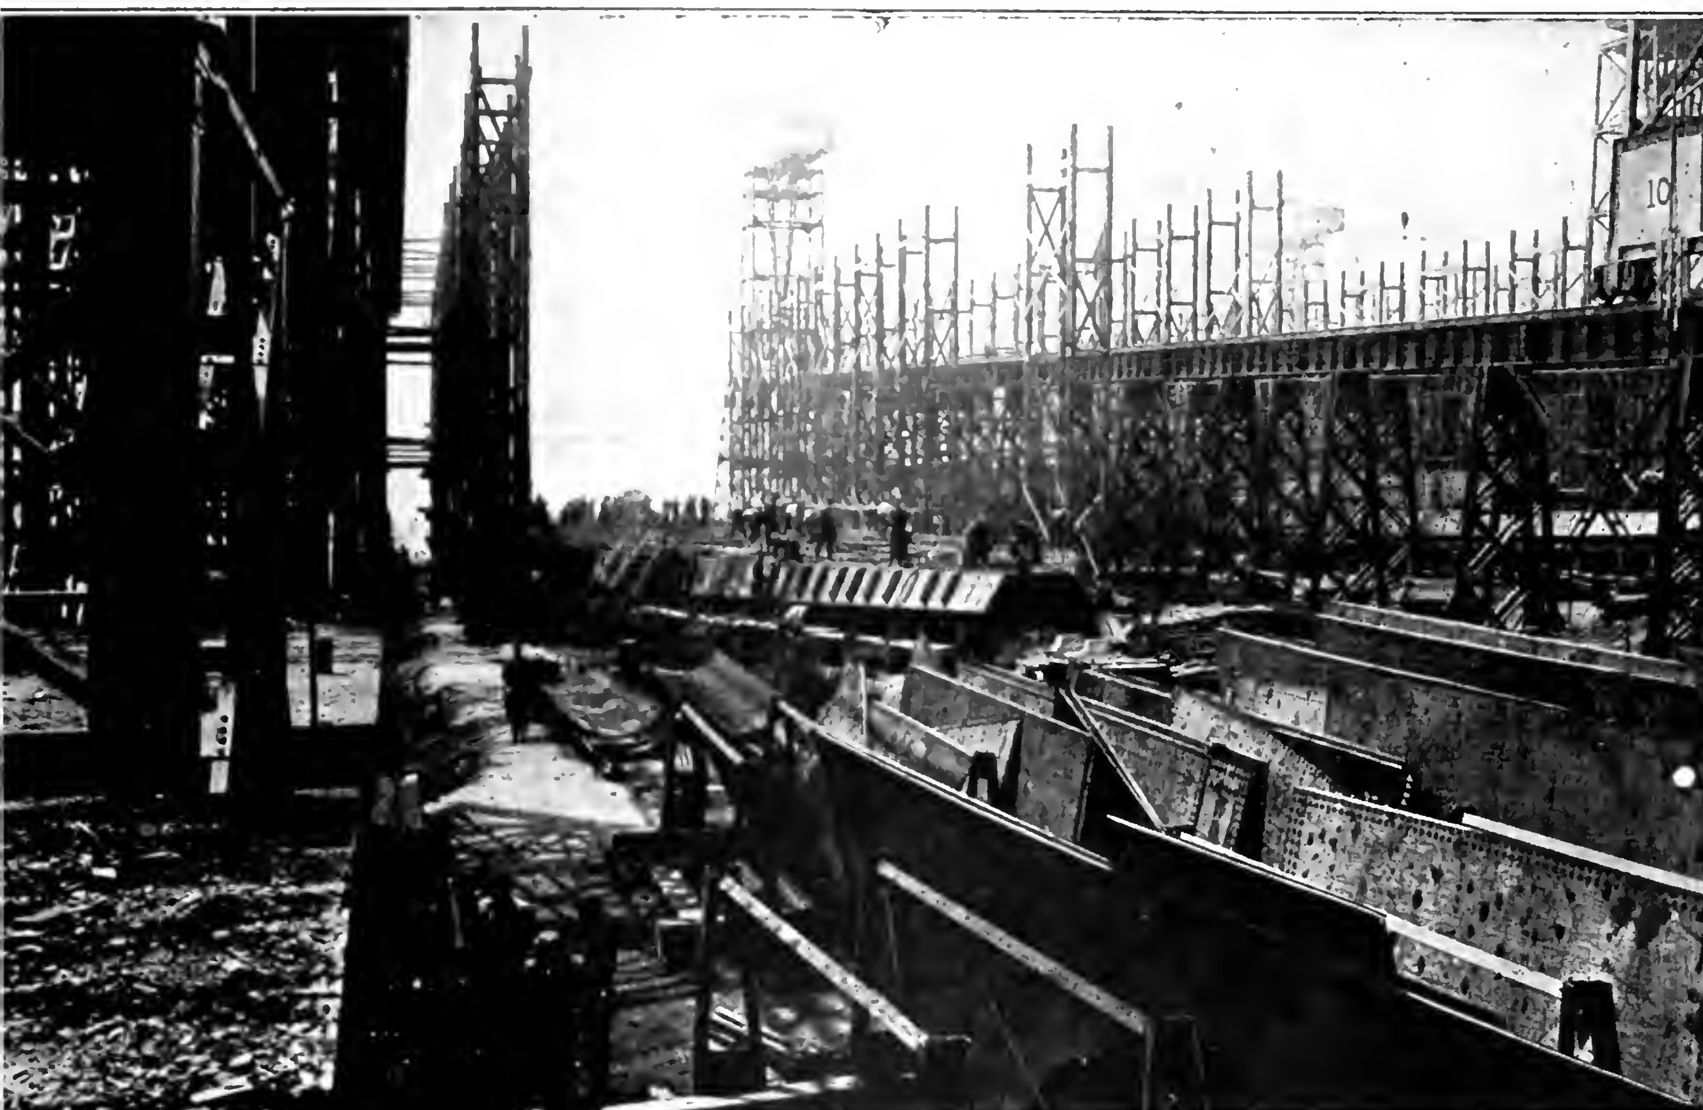

FIG. 9. SHIP ERECTION WORKED FROM WAY-HEAD STORAGE GIVING TWO OR THREE DAYS' SUPPLY

heet (no partial shipments are allowed), and at the ame time makes out a Manifest (see the form, Fig. 6). The material is delivered into custody of the boat foreman, who thereafter erects it as the requirements of his vorking force dictate. The manifest goes to the way lerk and is made the basis for the subsequent erection ecords.

Each piece entered on the manifest is transferred by he clerk to a Steel Requisition card, represented by Fig. . Horizontal numbering along the upper edge of this ard, 1 to 31, guides the attachment of a tickler tab ndicating the approximate date on which the piece hould be erected. These steel requisition cards, placed n a file case, form the clerk's check on the erection operation, and are the basis for the final cost sheet. A card s taken out of this file when the foreman's daily erection report shows that the corresponding piece has been erected in the ship; it is dated with the date of erection, and the piece mark and weight are entered on a Master Bill of Material, Fig. 8, which, when complete, goes to the cost department.

A check on the foreman's erection reports is had by noting when any steel requisition card remains in the file for some time after the estimated date of erection. The clerk can then take this card, locate the piece on the ship or in the way storage racks, and make corrections accordingly in his bill of material.

Advance notification, interleaved with the way orders as already described, are so placed as to allow about 10 days before date of erection for lifted material, and 18 days for assembly sections. The clerk sends these orders forward to the shop and assembly departments, each of which has an independent organization. The assembly department is organized in effect as a hull, with a foreman in charge. More elaborate organization is represented in the shop.

A clerk of the production department is located in the

shop, for handling the orders by which all work is initiated and routed. The shippers of the shop also are under control of the production department, and govern their reports and correspondence accordingly. Incoming orders arrive either from the way clerks (for lifted material) or from the dispatching office of the production department (for templeted material). In either event, the routing of the material through the shop is set forth on a standard form for the piece in question, on which are noted the successive operations required for its fabrication.

The ship erection schedule (Fig. 5) serves not only for control of the yard operations, but also for scheduling the bridge-shop orders. Basing the calculation on the time when a given piece will be required on the shipway, according to the erection schedule, successive allowances are made for storage (three days minimum), transportation from the bridge shop, time of fabrication in the bridge shop, transportation from mill, and time in mill.

These calculations are all recorded graphically on a series of charts, and the mill and bridge-shop orders are made out to correspond. Prints of these charts are allotted to each hull, and the actual mill and shop shipment and receipt times are marked in red on these charts, thus giving a graphical comparison with the scheduled or order time. One of the interesting results of an examination of these charts at Bristol is their showing the lag of mill and shop fabrication behind schedule time in spring and early summer of the current year, and the rapid improvement of these conditions, up to a marked lead over the schedule at present.

System Similar for Other Departments

All other departments of the yard—machinery, rigging, fitting-out, and the like—are controlled by systems which are similar to that described for the hull construction, and modified to suit the needs of the particular service. This is true not only of the installation of these parts in the ship, but also of the shop and store elements.

Orders for certain parts of the work of the equipment departments are interleaved with the hull construction orders, in the way clerk's order file. Thus, most of the ship tank piping is installed during the erection of the hull, and a certain amount of other equipment is put in. In addition, a distinctive practice of the Bristol yard is to install boilers and turbines in the hull before launching. This practice was followed for the first four ships built and will be continued, except in case of delay in the delivery of machinery. The parts in question can all be handled by the ship erection cranes, which, with an individual capacity of 15 tons, can handle 30-ton loads when two cranes are worked together. The added weight of the machinery is considered an advantage in launching, besides which a great amount of time is saved at the fitting-out dock.

A. H. Cooke, production manager, is in charge of the scheduling and routing work briefly sketched in the preceding. The principal officials of the company in active charge of shipbuilding operations are R. H. M. Robinson, president; W. T. Smith, vice-president; G. C. Thayer, general manager, and D. D. Smith, assistant general manager. H. E. Frick is authorized representative at the plant for the Emergency Fleet Corporation, representing Admiral Francis T. Bowles, assistant general manager of the Emergency Fleet Corporation, who is in charge of the fabricating yards and has general supervision also of the Delaware River district.

Conveyor Handles Freight at River Port

A FREIGHT-HANDLING conveyor for transferring freight between boats and cars at the Mississippi River port of Alton, Ill., is shown in the accompanying view. The carriage or frame travels on a track at right angles to the freight tracks, and carries a 45-ft. conveyor boom, which can be adjusted to the level of the deck or cargo hatch of the barge or steamer. At the head of this conveyor is a 20-ft. horizontal conveyor extending to the freight cars, and the farther end of this can be raised so as to load the car to its full capacity. A third 15-ft. section, not shown in the view, forms an extension for reaching cars on another track. When the carriage is run to the outer end of its track the boom can reach a barge or steamer outside the one moored to the dock.

Two classes of freight are handled by the conveyor, half of its width forming a continuous flat traveling apron or platform for boxes and other packages, while the other half has crossbars bent in concave form to receive barrels. The conveyors travel at a speed of 80 ft. per minute, and are all operated from a 15-hp. motor on the carriage. This conveyor was built by the Brown Portable Conveying Machine Co., Chicago. It is installed at the new waterfront dock and terminal, of the Illinois Terminal R.R., which was described in *Engineering News-Record* of March 7, 1918, p. 448.

FREIGHT CONVEYOR FOR TRANSFER BETWEEN BOATS AND CARS ON MISSISSIPPI RIVER AT ALTON, ILL.

Are American Engineers and Contractors Wanted in France?

Reports from French and Belgian Sources Show That Preference Will Be Given to Native Organizations and Men

AMERICAN engineers and contractors are asking to what extent they will be called upon to help reconstruct France and Belgium. Inquiries made by *Engineering News-Record* at all the official sources in the United States indicate that, although a large amount of American and foreign construction machinery will undoubtedly be used, participation on the ground by American engineers and contractors will probably not be encouraged by the two countries. The purchase of raw materials and semi-finished products, will, it appears, be confined as far as possible to home markets. Large-scale production of certain construction materials has already begun in Belgium.

Engineers on the staff of the French High Commission are unable to say what the reconstruction policy of France will be, because the recently organized Ministry of Reconstruction has not had time to forward plans. The impression prevails in both the New York and Washington offices of the commission that the ministry is awaiting some indication of the trend of the peace conference. The Washington office states that, although American engineers would be welcome in France as citizens of a country with which the warmest ties of friendship existed, French engineers, on account of their long service and great sacrifices in the war, will naturally receive preference. It is believed, however, that the supply of engineers will be ample, because of the comparatively short time during which it was necessary to use engineer regiments in front of the fighting lines.

Same Conditions in Belgium

The same conditions exist in Belgium. The Belgian information bureau in Washington states that the services of those engineers only who possess extraordinary ability or highly specialized talent will be needed, but both the French and Belgian officials say that there will probably be a call for engineers familiar with such American construction machinery as may be bought. But American engineers as well as machinery are desired by Belgium in the development of her African possessions.

The United States Bureau of Foreign and Domestic Commerce says that the question is largely one of credit. Purchases will be made in those countries holding the largest credits, and since it is probable that the United States will be the leading country in this respect it will also be the leading country supplying machinery and materials. As mentioned above, however, the local supply of raw materials in France and Belgium will probably be ample. Figures quoted by a German investigator in the Berliner *Tageblatt* recently, in discussing the Lorraine iron supply, give an index of the amount of iron available to France due to the recovery of that territory. The German writer stated that in 1913 the Lorraine and Luxemburg mines (the two industries being closely related) supplied 28,500,000 tons out of a total of 35,000,000 tons of iron ore used in the whole of Germany. He pointed out, however, that in the utilization of this large amount of raw material the French are handicapped by lack of furnaces and mills, they having been more concerned in selling the raw ores to foreign countries than in reducing it to the finished or semi-finished state themselves. He also stated that lack of available coke in France, (Germany having obtained it from her own sources) was another obstacle. These conditions, it is pointed out in Washington, will require a large amount of machinery and plant of a highly engineering character.

In commenting on the problem Richard L. Humphreys, chairman of the Construction Material Section of the War Industries Board, pointed out that before any extensive purchases could be made or work done a revision of credits would be necessary. The present war credits will cease to exist when peace is finally established. Measures will also be necessary to revive the purchasing power of the various European monetary units, Mr. Humphreys said.

Congo and Home Country

A student of Belgian home and colonial affairs, who resides in Washington, states that the finances of Belgium were in an anomalous condition in that although the home country is in financial difficulties, the colonies on the Congo have immense reserves of money and wealth. The Congo Free State was originally the personal property of the late King Leopold of Belgium, who, he explained, bequeathed it to the state at his death. The country, however, accepted the bequest in such a way that the revenue could not be used directly by the state, and although there are ample funds in the colonies they are not available for use in reconstruction work. The accumulation of this revenue, he stated, is very large, and the Government is working on a solution of the problem, through parliamentary or other action. It will therefore be some time before the work can be commenced on a nation-wide scale.

Other factors that will delay the final rehabilitation of the industrial life of Belgium are indicated in a recent United States commerce report. Industrial rehabilitation is vital, it states, yet the repair of the damaged ports, railways, highways and canals will be necessary before industrial reconstruction can be started. The railway equipment and rolling stock saved from the German invasion have been worn out from continuous military use on the French railways, and the network of canals will be out of use until it is repaired and the barges are replaced. The Belgian ports capable of accommodating seagoing vessels are not yet available for commerce, and the shipping itself has either been destroyed or diverted to other routes. Port equipment has been badly damaged or completely destroyed by the Germans, and the bridges and roads connecting the ports with the interior have been wrecked—so that even if sufficent shipping facilities were to be had the means for discharging and distributing cargoes is not available. The problem of the reconstruction of Belgium, the report points out, does not mean solely the furnishing of goods which she will need, but the complete rehabilitation of trade, industry and agriculture, as well as the actual rebuilding of devastated cities, towns and villages and rural regions.

It is also reported that extensive preparations for the further development of the Belgian Congo have been in progress for some time. A hydro-electric plant has already been erected, and the electrolytic reduction of copper commenced. The dumps of the copper workings that have been in existence for thousands of years are being worked over, and in the first four months of the plant's operation 40,000 tons of copper were shipped to England. It was found that the copper content in these dumps averages from 40 to 50 per cent.

Edmund Laplae, professor in the University of Louvain, and director general of the colonial ministry of Belgium, has been in the United States studying American methods and machinery. He has returned to Belgium to make his report, but will come back soon to engage American engineers and to purchase American machinery to be used in the development of the Congo colonies. It is also stated that he will not make any effort to interest capital. The development of the Congo had already been started before the end of the war, and as much equipment as could be gotten through the various embargoes has been sent over. A steamboat, similar to those used on the rivers of the Western United States, was needed for the upper Congo. M. Laplae found one in Pittsburgh ready to be shipped on a South American order, but held up on account of lack of cargo space. He bought it from the original consignees and managed to have it shipped to the Atlantic coast, where he obtained cargo space for it by an agreement with the Federal Government to ship a cargo of rubber in return. The steamboat is now in operation on the Congo.

Representatives of the Department of Commerce who have been studying the problem state that the people of France and Belgium hope and expect that preparations for the forwarding of needed supplies will begin promptly, especially since the invaded portions of the two countries have been reoccupied and it is possible to get definite particulars as to their requirements. The Belgian consul at New York states that information regarding his country may be had from the *Comptoir National pour la Réconstruction de la Belgique*, 15 Rue Louis le Grand, Paris, France, and that it has requested duplicate catalogues. Information regarding France may be had from the French High Commission, Washington, D. C., and catalogues should be sent in duplicate, in care of Lieut. Maurice Boyer, of the commission.

Four Methods of Sewage Treatment Studied at New Haven Testing Station

Miles Acid Process Advised for First of Four Permanent Works Rather Than Fine Screens, Imhoff Tanks (Each with Chlorination) or Activated Sludge—Results of Analysis, and Cost Estimates

By C.-E. A. Winslow
Professor of Public Health
Yale School of Medicine

AND

Dr. F. W. Mohlman
Chemist, Connecticut State
Department of Health

Eleven months' experiments at the sewage-experiment station established by the City of New Haven, Conn., have led to the conclusion that for the particular and somewhat unusual local conditions there prevailing the Miles acid process of sewage precipitation, with recovery of grease and fertilizer, is the best available method for one of the four plants necessary, and may prove advisable for the other three. The reason for the tests, the results obtained and the conclusions drawn are here presented, except that the Miles acid process is not taken up in detail because it was treated separately and at length in *Engineering News-Record* of Dec. 5, 1918, p. 1034.

New Haven has a population of approximately 160,000, and is sewered on the combined plan. The water consumption is very high, and the total sewage flow is estimated at about 35,000,000 gal. per day. Thirty million gallons are discharged from the main sewers of the city at five different points about the harbor. The present outfalls are all above low-water mark; the upper harbor is shallow (averaging less than 5 ft. in depth outside of the main channels), and the sewage as it spreads over the flats and deposits sludge upon them produces in many places a condition of gross nuisance. The pollution of bathing beaches and shellfish layings constitutes a very real danger to public health. The United States Bureau of Chemistry in 1915 forbade the shipment in interstate commerce of oysters taken from large areas in the harbor "unless such oysters were purified by transplanting them in nonpolluted water for at least seven days before shipment." In the following year the United States Public Health Service made an exhaustive study of harbor conditions. This resulted in the conclusions that the harbor was grossly polluted, that shellfish taken therefrom are filthy, dangerous and unfit to be eaten as taken from the area, and that bathing and swimming in the upper harbor are unsafe.

As a result of these conditions, an aldermanic and citizens' committee was organized in the spring of 1916 to study the problem. The committee consisted of Prof. C.- E. A. Winslow as chairman, Prof. S. E. Barney, A. B. Hill, H. B. Sargent and Aldermen J. W. Murphy and F. S. Nelson. It was assumed on the testimony of those most familiar with the local situation that it would not be economically advisable to attempt to intercept the sewage from the various outfalls and treat it at a single point, but that at least four different treatment plants must be contemplated, all discharging into the inner harbor. It appeared essential, however, to provide for outfall sewers to carry the sewage to submerged outlets in the main channels. The digestive capacity of the harbor waters is such as to render the production of a nitrified effluent unnecessary; but it was felt that a substantial removal of suspended solids and of sewage bacteria was demanded in order to avoid sludging up of channels or pollution of bathing beaches and shellfish layings.

To determine what methods of treatment were best

adapted to the solution of the local problem, as outlined above, an experiment station was operated for 11 months—June, 1917, to April, 1918. The total cost of the investigation was slightly less than $18,000. The immediate direction of the experiments was in the hands of the chairman of the committee, with Dr. F. W. Mohlman as chemist in charge and W. S. Sturges, Jr., as bacteriologist.

The experiment station was located at the outfall of the East St. sewer, which is not only the principal sewer of the city (flow of approximately 15,000,000 gal. a day), but also the most important one to study on account of its high content of industrial wastes. Special studies of certain processes were also made during the spring of 1918 at an outfall serving a residential district.

The processes studied were (1) fine screening; (2) Imhoff treatment; (3) activated-sludge treatment, and (4) Miles acid precipitation—all but the last followed by chlorine disinfection. The sewage for the experiments was obtained in a somewhat original manner, in order to avoid the breaking up of sludge solids by pumping. A considerable part of the flow in the sewer was diverted through a forebay from which the sewage needed for the experiments was withdrawn by means of a bucket elevator. This device proved highly successful and yielded an entirely normal fraction of the sewage flow suitable for accurate screening tests.

The sewage was distributed to the various devices over movable notch and rectangular weirs from a weir box in which the head was controlled by a Wallace & Tiernan regulator, operating a butterfly valve in the raw-sewage flume.

Peculiarities of the Raw Sewage

The sewage of the East St. sewer proved to be highly abnormal in several respects. It was very dilute, averaging for the 11 months 4.4 ppm. of ammonia nitrogen, 97 of total suspended solids, and 63 ppm. of volatile suspended solids. It contained during the first seven months of operation over 1000 ppm. of chlorine, which condition was traced to a million gallons a day of sea water used as condenser water in an industrial plant. Its bacterial condition was most peculiar. Samples collected on Sundays, Saturday afternoons and at 8 a. m. on certain week days gave normal results (1,470,000 bacteria and 143,200 colon bacilli per cubic centimeter); but samples collected during the industrial day showed only 160,200 bacteria and only 9600 colon bacilli per cubic centimeter. This condition we found to be due to the antiseptic action of copper salts derived from the washing of shells in a large munition factory Such a phenomenon appears not to have been previously recognized in the literature of sewage disposal, although recent studies by the Connecticut State Department of Health indicate that it is by no means unique, and that certain peculiar results noted in the Waterbury experiments in 1909 must have been due to the same factors. The effect of antiseptic wastes of this kind upon biological processes is of course a profoundly important one. The raw sewage showed an average "relative stability," or pseudo-stability, as we preferred to call it, of 58, when measured in the usual manner.

Screening studies were made with stationary screens 2 ft. wide by 3 ft. long, placed on cleats inclined downstream at an angle of 45° in a screen chamber 8 ft. 10 in. long by 2½ ft. wide and 2½ ft. deep. Two types of screen were tested, one of 30-mesh monel-metal wire cloth, and the other of galvanized-iron plates perforated with slots 1¼ in. long and $\frac{1}{16}$ in. wide. Sewage was in all cases passed through the screen under test at an initial rate of 100,000 gal. per day. As the screen clogged, the sewage gradually built up behind it, and in from 15 min. to one-half hour, when the loss of head had reached 2 ft., a second screen of the same type was placed in the chamber, resting on cleats 2 ft. below those on which the first was placed. After the second was in position, the first was pulled out of the chamber and allowed to drain. The second screen was kept in position until the loss of head had again reached 2 ft., when the sewage was bypassed, and the sewage remaining in the screen chamber was removed by the opening of vents in the side of the tank. After the sewage had been drawn down to within ½ in. of the bottom of the tank the second screen was removed and drained. The amount of sewage passed through the two screens in each experiment averaged about 3000 gallons.

TABLE I.—AVERAGE RESULTS OF SCREENING EXPERIMENTS

Sewer	Screen	Wet Screenings, Lb. per M.G.	Solids in Screenings, Lb. per M.G.	Solids, Per Cent. Volatile	Suspended Solids ppm Influent	Suspended Solids ppm Effluent	Suspended Solids Per Cent. Reduction	Settleable Solids, Per Cent. Reduction
East ..	Wire mesh	1,367	178	71	145	123	15	41
	Plate. .	665	86	82	137	126	8	29
Boulevard	Wire mesh	1,347	138	78	134	117	12	43
	Plate	386	28	82	135	132	3	29

After draining, the screenings were brushed off the screen and weighed, and the moisture content was determined. The effluent was sampled frequently during screening, and the suspended solids in the composite sample determined. Knowing the quantity of the sewage screened and the weight of the dry screenings, the parts per million of suspended solids removed and the per cent. of removal could be calculated.

Such studies of screening by the use of stationary screens is open to criticism on the ground that it permits a much greater clogging than would occur in practice with a revolving screen cleaned automatically during the process. The clogged screen will of course effect a greater purification than one that is kept clean. If the head were allowed to increase beyond a certain point, the pressure would operate in the opposite sense by forcing an undue proportion of solid matter through the meshes. With a loss of head never rising above 2 ft. this criticism cannot be made, since this is a range within which commercial screens are supposed to operate Our method of experimentation was therefore exceedingly favorable to fine screening, and working with an unusually fresh sewage we expected to obtain good results. As indicated in Table I, however, even the wire-mesh screens effected only 15% removal of suspended solids in the case of the East St. sewer, while the Boulevard domestic sewage (in which the solids were in a more finely divided state) gave an even lower degree of purification, the plate screens proving in each case inferior to those of wire mesh.

Altogether, it seems evident that fine screening, with

either wire screens (30 meshes to the inch) or plate screens ($1\frac{3}{4}$ x $\frac{1}{16}$-in. slots) cannot be expected to accomplish any important degree of purification with either of the sewages studied. Such screens will, of course, remove the grosser and more obvious floating solids and, where it is only necessary to avoid visual offense, they may be of great value. Where a substantial removal of suspended matter is desired, such as is accomplished by tank treatment, fine screens will not serve.

Our results are in accord with the general conclusions of conservative sanitary engineers. George W. Fuller, who is a firm believer in fine screening for situations to which it is adapted, estimates a removal of only 10% of suspended solids by such treatment. It is quite certain that a full-size installation of moving screens would accomplish less than the purification indicated by our tests. At Cleveland, several years ago, preliminary studies, made like our own with stationary hand-operated screens, gave a removal of 25 to 28%, while an actual Reinsch-Wurl installation (on another outfall sewer of the city) took out only 4% of the suspended solids present. Any such degree of purification as was indicated by our studies, or by the Cleveland experience, would, in our judgment, be inadequate for an effluent to be discharged into a shallow harbor with a narrow dredged channel, like that at New Haven.

Results of Imhoff Treatment

The Imhoff tank used in our experiments was constructed of tongue-and-groove spruce, with calked seams. It was 16 ft. long, $4\frac{1}{2}$ ft. wide and $11\frac{1}{2}$ ft. deep. The flow chamber extended for the full length of the tank, with gas vents 8 in. wide on each side. The flow chamber was constructed of heavy galvanized iron, with a triangular beam below the vent. The vent was 8 in. wide, and the seal overlapped each side 2 in. The sides of the flow chamber sloped at 60°, so that no difficulty was encountered from solid matters clinging to the slope. The capacity of the flow chamber was 840 gal. The detention period was theoretically 2 hours when treating 10,000 gal. of sewage per day. The linear velocity of the sewage was 0.15 ft. per minute.

The sludge compartment was out of proportion to the flow chamber, being relatively much larger than would be designed for a full-size plant. It was assumed that a large sludge compartment might be needed on account of the shallowness of the tank. The bottom of the tank was built in the form of two inverted pyramids with the sludge draw-off pipes just above the apices. When the tank was first filled with sewage it leaked badly. It was made tight only after many trials and was finally placed in service in November, 1917. It was unfortunate that operation should have been begun in winter, but by the end of April the increasing warmth of the season should have brought about normal conditions. Yet the results were at no period satisfactory, and they became worse as time went on. The average removal of total suspended solids for the six months' period was only 43 per cent., of volatile suspended solids only 38 per cent., and of settleable solids only 69 per cent. Sludge drawn from the tank at the close of the experiments was reddish-brown in color and highly offensive and dewatered badly, having in no respects the characteristics of a normal Imhoff sludge.

It seemed evident that with so weak a sewage as that studied sedimentation would not yield a very high degree of purification (this was confirmed by one month's study of plain sedimentation, which showed only 41% removal of total suspended solids) and that some factor, presumably the presence of the antiseptic industrial wastes, prevented the normal digestive action of the Imhoff tank. In view of the latter fact, it seems inadvisable to recommend this method of treatment for a disposal plant in a thickly settled district, on account of the danger that the operation of the tank and the removal of sludge therefrom, with a sewage of so abnormal a character, might be productive of local nuisances.

Activated-Sludge Treatment

Our activated-sludge experiments were made on the continuous-flow basis. The aërating tank was 16 ft. long, 4 ft. wide and 8 ft. deep. At the bottom of the tank the sides sloped at 45° to a trough 1 ft. wide, running the full length of the tank. An iron frame in which were cemented 15 filtros plates was cemented into this trough. The air was admitted at the inlet end of the trough, and the water which filtered through the plates could be drawn off at the outlet end. The air was compressed to 3.5 lb. pressure by a hydro-turbine having a capacity of 20 cu.ft. of free air per minute, the flow being measured by means of a venturi tube.

The settling tank was 4 x 4 ft. in plan, and 12 ft. deep to the bottom of the hopper. This hopper sloped at 60° to a sump in which was cemented a 3-in. ell connected to the suction of an air-lift pump. The sludge deposited here could be pumped back to the aërating tank, being measured on the way in an orifice box. A baffle $7\frac{1}{2}$ ft. deep extended across the center of the settling tank. This baffle was first placed 3 ft. from the inlet weir and 1 ft. from the outlet weir, but the upward velocity of the effluent was too strong and carried particles of sludge over the outlet weir. After the baffle was placed in the center of the tank no sludge was lost in this way, the theoretical upward velocity being decreased by this change from 4.8 in. to 2.4 in. per per minute. The capacity of the aërating tank was 3100 gal., that of the settling tank 1150 gal. While treating 17,000 gal. of sewage per day with 50% returned sludge the aëration period was 3 hours, the settling period 66 minutes.

The activated-sludge process was studied less as an oxidizing than as a clarifying process, in the same way in which it was used at Cleveland. It was thought that activated-sludge treatment and chlorination might compete with Imhoff treatment and chlorination if the air and tank space required for the former process could be cut down considerably, and if the amount of chlorine required for disinfection were much less in the former case than in the latter. For this reason small amounts of air and short periods of aëration were used and no attempt was made to obtain full nitrification of the effluent.

The process was at first studied with an aëration

period of 2.5 hours, a mixture of 73 parts of very dilute sludge per 100 volumes of sewage, an air supply of 1.3 cu.ft. per gallon of sewage, and a sedimentation period of 55 min. All of these variables were modified at different times, the aëration period being varied between 2.5 and 10 hours, the proportion of sludge from 50 to 73 volumes per 100 volumes of sewage, the air supply from 1.1 to 2 cu.ft. per gallon of sewage, and the sedimentation period from 30 to 78 min. At no time and under no conditions could really satisfactory results be obtained. The sludge accumulated slowly, was rarely well flocculated and did not settle well. The effluents never showed a normal clarity. The removal of total suspended solids averaged only 55 per cent., and of settleable solids only 74 per cent. The nitrogen content of the sludge averaged only 3.23 per cent. The failure of the process no doubt was due in part to the design of the settling tank, the small size of the sludge pipes and the lack of a separate sludge-aërating tank; but we are satisfied that the primary reason for the poor results obtained was the presence in the sewage of the antiseptic industrial wastes which would render hazardous and uncertain the use with this sewage of any process depending on biological activities.

Experiments on Chlorination

The effluents from the screen chamber, the Imhoff tank and the activated-sludge process were conducted by wooden flumes to small baffled tanks, giving detention periods of 2 to 5 min. in which they were treated with liquid chlorine delivered from a special Wallace & Tiernan solution-feed apparatus. The samples of chlorinated effluent were held in the sample bottles for 30 min. before plating, to reproduce the action of the small storage tanks that would be required in an operating plant.

To interpret our results, it was necessary to fix on some tentative standard which might be considered adequate and satisfactory. For this purpose we have assumed as the ideal to be attained that the final disinfected effluent should contain not over 10,000 bacteria per cubic centimeter, and not over 1000 colon bacilli per cubic centimeter, as a general average. This represents a purification of over 99% for the normal sewage and about 90% for the day sewage at East St. containing the copper wastes. Activated-sludge effluent required 3 ppm. of chlorine to produce this result, and screened sewage, five parts, while Imhoff effluent showed average counts somewhat above the standard even after treatment with six parts, and crude sewage after treatment with 8 ppm. In making estimates as to the cost of chlorination of screen and Imhoff effluents, we have assumed that five parts of chlorine would produce a fairly satisfactory degree of purification, basing this assumption chiefly on the results of the colon test, which is of greater significance than the count of total bacteria. This amount might very probably have to be increased in practice, however, particularly in the case of the Imhoff effluent.

The process of precipitation with sulphurous acid, patented by George W. Miles, and reported on so favorably by Prof. R. S. Weston of the Massachusetts Institute of Technology (*American Journal of Public Health*, 1916, VI, p. 334) seemed deserving of special attention in our experiments, in view of the fact that such a process would not be interfered with by antiseptic wastes and would be favored by the low alkalinity of the East St. sewage, and also because it yields a clarified and disinfected effluent such as was desired in view of local conditions. [These tests were detailed at length in an abstract of a paper by Professor Winslow and Dr. Mohlman, printed in *Engineering News-Record* of Dec. 5, 1918, p. 1034.—Editor.]

Comparison of Various Processes Studied

The general average results of the various processes studied are indicated in summary form in Table II.

Of the various processes available for the treatment of city sewage, it is obvious that any form of filtration would be out of the question for a disposal plant located at the East St. outfall. Our studies have indicated that activated-sludge treatment cannot be considered, on account of the presence of industrial wastes which prevent the bacterial activities upon which this method of treatment depends. In order to secure the results desired, a substantial removal of suspended solids and a reasonably high degree of bacterial purification, there remain three possibilities: (1) Fine screening followed by chlorination; (2) Imhoff tank treatment followed by chlorination, and (3) the Miles acid process. It has been pointed out above that fine screening gave us a removal of suspended solids which we did not consider adequate for the protection of the harbor, and that the character of the sludge formed in the Imhoff tank was so abnormal as to threaten the possible production of a local nuisance. We have nevertheless given careful consideration to all three of these processes and have prepared for each of them preliminary cost estimates which are shown in Table III. (See next page.)

TABLE II.—COMPARATIVE RESULTS OF VARIOUS PROCESSES: GENERAL AVERAGES OF PER CENT. OF PURIFICATION

	Ammonia (N)	Turbidity	Solids: Total Suspended	Solids: Volatile Suspended	Solids: Settleable
Wire-mesh screens	..	...	15	...	41
Plain sedimentation	—30	23	41	34	86
Imhoff treatment	—12	14	43	38	69
Activated-sludge treatment	13	44	55	50	74
Miles acid treatment	0	36	61	54	90

The estimates are based on the production of SO_2 gas by burning sulphur (assumed to cost $36 a long ton) and on drying from 85 to 10% moisture (coal assumed at $7.50 per ton). We have estimated a very high cost for the construction of Imhoff tanks ($20,000 per 1,000,000 gal.) on account of peculiar local conditions of the outfall, since the tanks would have to be built for the most part below tide water. The cost of chlorination is based on the use of five parts of available chlorine per million parts of sewage, an amount which we have found essential for the treatment of either screened or clarified sewage. It is very probable that in actual practice more than five parts might be necessary.

It appears from these estimates that the acid treatment of the sewage from the East St. outlet should

be materially cheaper than either Imhoff treatment or fine screening, under existing local conditions. With a fall in the price of grease after the war the outlook would be less favorable. Even if all revenue from the sale of grease and fertilizer were eliminated, however, the cost would not be very much greater for acid than for Imhoff treatment. Other conditions make the case for the Miles process at this outfall almost irresistible. Our studies have shown that fine screens will remove only a small proportion of the suspended matter from either the East St. or the Boulevard sewers, and we are of the opinion that the purification so effected would not be adequate to prevent sludging in the dredged channel into which the effluent must be discharged. On the other hand, our experiments with Imhoff treatment of the East St. sewage have been most unpromising, as noted above, on account of the antiseptic action of the copper present in the sewage.

Above all however, the thing that counts most heavily in favor of the Miles process under the conditions obtaining at New Haven is its freedom from nuisance. If heavy costs for interceptors and pumping are to be avoided, the sewage of the city must be disposed of at four different points, all of them in thickly settled areas where offensive odors must be prevented at all costs. Furthermore, the problem of disposal of sludge and screenings would present peculiar difficulties. A process of treatment which should be free from local nuisance and which wholly eliminates the problem of sludge disposal is ideal for such a local condition.

Normal Sewage at New Haven

Aside from a short series of screening tests and a month's operation of the Miles acid process on the Boulevard sewer, we have conducted no experimental work on the sewage discharged from the other main outfalls of the city. We know, however, from the United States Public Health Service survey and from analyses of sewage from the other outfalls made under the direction of Prof. S. E. Barney, that the sewers of New Haven, aside from that at East St., carry a fairly normal flow of domestic sewage. From the conditions of the case the processes likely to prove successful are limited to the same three combinations tested at East St.; and we know pretty well what fine screening and Imhoff treatment are likely to accomplish with an average American domestic sewage. Activated-sludge treatment could no doubt be applied successfully to such sewages as those in question, but the operation of four small units of this type would certainly be expensive, since the cost of power in New Haven is high and the sewage of the city is in general so weak that a relatively small revenue could be estimated from the recovery of nitrogen in the sludge.

To obtain an idea of the relative cost of the three processes which seem most suitable for local conditions, we prepared preliminary estimates for the treatment of the sewage of the Sea St. outfall, based on our studies of its principal tributary, the Boulevard sewer. These figures [$9.60 for Miles acid, $12.14 for Imhoff tanks and chlorination, and $12.35 per 1,000,000 gal. for fine screening and chlorination—Editor], which should be fairly typical for the other New Haven outfalls, show that the Miles process in this case is considerably more expensive than at East St.—first, because of the higher alkalinity of the sewage, and, second, because of the fact that the plant would be smaller (6,000,000 gal.) and costs per unit volume therefore larger. In particular, the cost of superintendence rises to a high figure, since we are convinced that a chemical industry of this nature cannot be carried out without expert guidance. Imhoff treatment is slightly dearer, for the same reason, in spite of lower construction costs.

TABLE III.—ESTIMATED COST OF TREATMENT OF EAST STREET SEWAGE PER MILLION GALLONS

	Miles Acid Process	Imhoff Tanks and Chlorination	Fine Screens and Chlorination
Tanks and buildings (interest and depreciation)	$2.47	$5.28	$4.50
Acid treatment	6.93	.....	.....
Drying sludge	2.09	.....	.....
Degreasing sludge	1.78	.....	.....
Redrying tankage	.17	.....	.....
Superintendence	1.06	.46	.46
Labor on tanks and screens	1.00	1.20	1.42
Disposal of sludge or screenings	.....	1.00	.50
Chlorination	.....	4.05	4.05
Gross cost	15.50	11.99	11.03
Revenue	7.09	.....	.....
Net cost	8.41	11.99	11.03

No allowance has been made in these estimates for royalties on the Miles acid process, which is a patented one. Before definite plans are made proper assurance should be obtained that such charges would be reasonable. In the case of Imhoff treatment, royalties in the past have been small as compared with the total cost of treatment.

The same objections which militate against screens at East St. limit the promising possibilities at the Sea St. sewer to Imhoff and acid treatment.

The gross cost of the Miles process is very high, and with a new procedure of this sort, never yet applied to purely domestic sewage on a practical scale, it must be recognized that many factors, such as the difficulties in distillation and the deoxidation of diluting water caused by the contained chemicals, may cut heavily into the assumed revenue.

If the problem of the Sea St. sewer stood by itself, we should be somewhat in doubt whether to favor Imhoff or acid treatment, with the facts in mind. Since, however, the case for acid treatment seems so clear for the East St. sewer, we are of the opinion that it would be wise to delay construction at other New Haven outfalls until the acid process has been tried out on a practical scale at the point where it promises best results. If an acid treatment plant at East St. is successful, the drying and degreasing of the sludge from this and other plants could be conducted at one central location, the costs estimated for Sea St. would be materially reduced, and acid treatment might well prove economical for all the main outfalls of the city.

Lincoln Highway Maintenance in Pennsylvania

Pennsylvania has expended $747,505.78, during the past year in maintaining the Lincoln Highway, according to a statement prepared for the Lincoln Highway Association by J. Denny O'Neil, state highway commissioner. The main items of maintenance covered by this expenditure are: Surface treatment, 248 miles; reconstruction, 22½ miles; building of seven modern concrete bridges, and the necessary oiling. The report adds that this large sum was made necessary in great part by the thousands of United States Army trucks which used this highway during the year.

Aërial Cableways Successful in Northwest Shipyards

Similar to Loggers' Cableways—Ability To Get Men Expert In Handling Them Is One Secret of Success—Well-Planned Installations Are Fast and Flexible

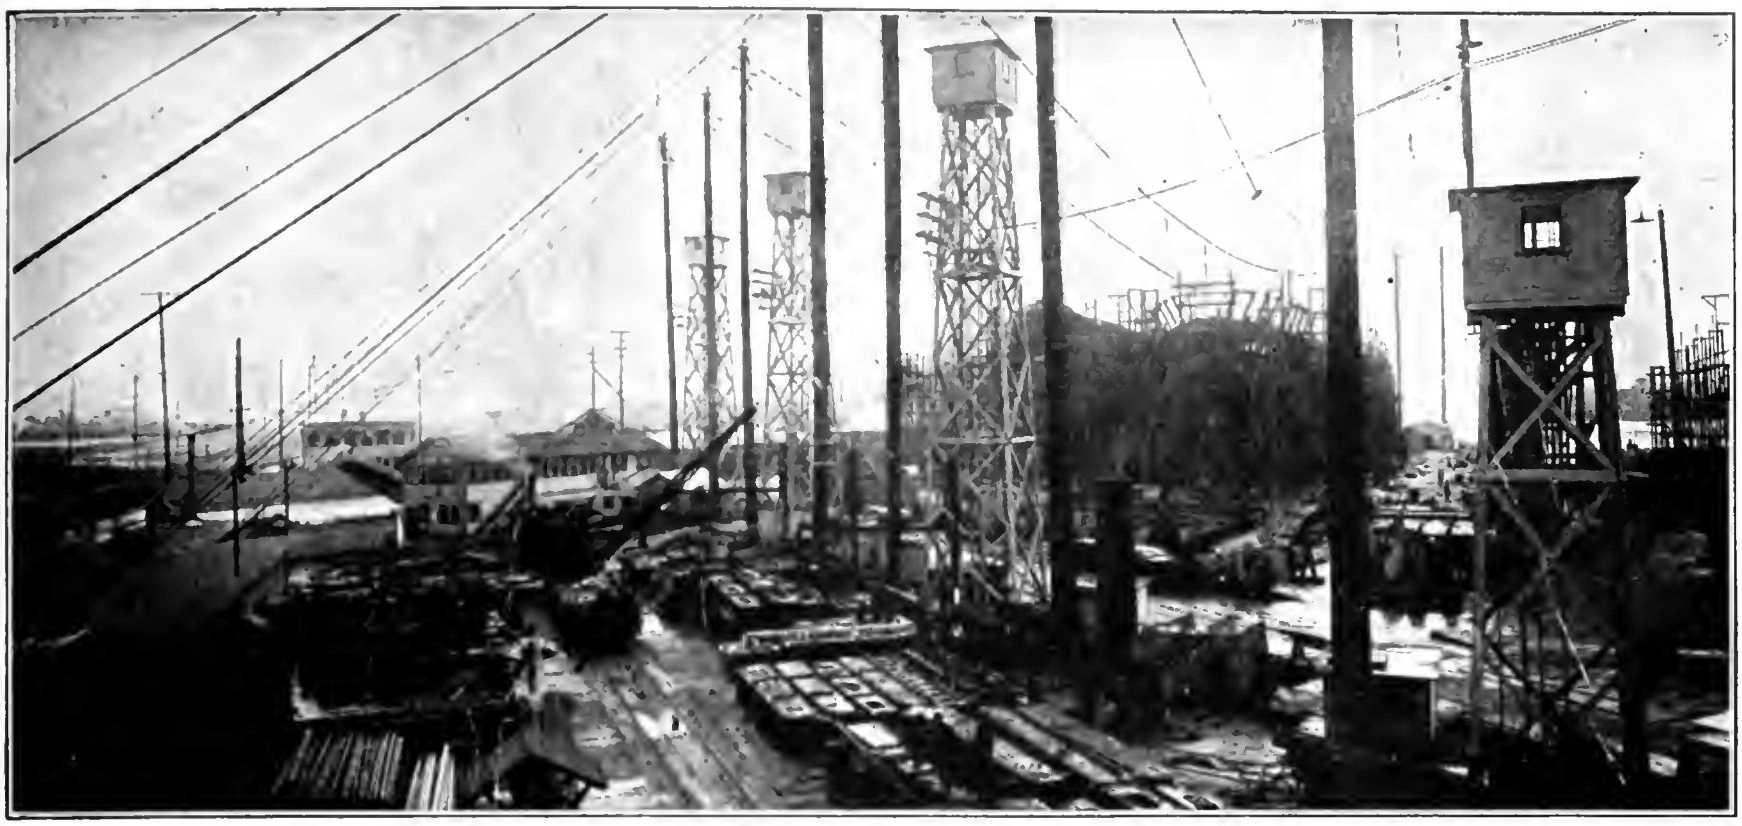

FIG. 1. THESE 125-FOOT TOWERS AT THE AMES YARD IN SEATTLE ARE FOR THE HOIST OPERATORS ONLY; THE WINCHES ARE ON THE GROUND

WORLD records in ship construction have been broken on the Pacific coast by yards handling materials with aërial cableways, a method which many shipbuilders do not regard with favor. Disfavor may be justified by the installations in some yards, but the good records of some of the well designed cableway systems and the high speed attained in placing steel speak for themselves. For example, the Skinner & Eddy yard at Seattle has recently launched fifteen 8800-ton boats in an average of 54.4 working days, and delivered them ready for service in an average total of 72.3 working days.

Moreover, the strong preference for cableways shown by managers of several successful steel shipyards indicates that the method will be for some time a factor in shipyard design. In fact, cableways are now being used in nine of the ten steel yards in the northern Pacific district of the Emergency Fleet Corporation. The first cost of an aërial cableway system is only a small fraction of the cost of overhead cranes, and the former can be built with materials quickly available on the Pacific Coast.

The aërial cableway idea was first applied in the Northwest early in 1915. When the Skinner & Eddy plant at Seattle was laid out in 1916 the system was installed on a comprehensive basis. Members of this firm had previously used cableways extensively in logging operations, and the methods employed in the woods were adapted to shipyard service. Expert riggers and operators were available from logging crews. Since that time the idea has been adopted by many of the new yards. Of course, the use of cableways presupposes the endwise delivery of material—that is, the cableway systems pick up material from storage inshore of the shipway and move it parallel to the keel. Thus, the system is best suited to yards in which the ways have to be built close together, and no storage alongside is available.

The layout and detail of design of the cableway systems vary greatly, but throughout the Northwest, in the more successful yards, there is a notable uniformity of main features. The most common arrangement is to have two cableways for each shipway, with bow and stern masts about 650 ft. apart. The bow and stern rows of masts are each tied together by cables at masthead, and are steadied by backstays and guys, as required. A three- or four-sheave tackle is usually put in the backstays to take up the slack in the main cables. The bow masts are usually set plumb, and the backstays are run out as far as anchorages can be conveniently placed. Where the ways front on deep water and it is inconvenient to use long guy lines astern, the stern masts are inclined outward, to increase the stability that may be obtained from short backstays and to keep the anchorages in shallow water.

It is the common practice to use counterweights on the dead end of the hoisting line and also on the carrier line, instead of making them fast to the masthead. This automatically prevents overloading the trolleys, and takes up slack in the carrier line. About one ton is used as the carrier-line counterweight; the hoisting-line counterweight equals the maximum load, usually about 2½ tons. The main cables are kept pulled up taut, with a sag not to exceed 3% or 4% of their length.

In one of the Northwest plants a temporary guy line was removed during construction before the permanent connection had been effected, and, as these ways were on an acute angle with the shore line, the entire row of bow masts fell over, doing considerable damage. In another plant the bow masts collapsed when one of the

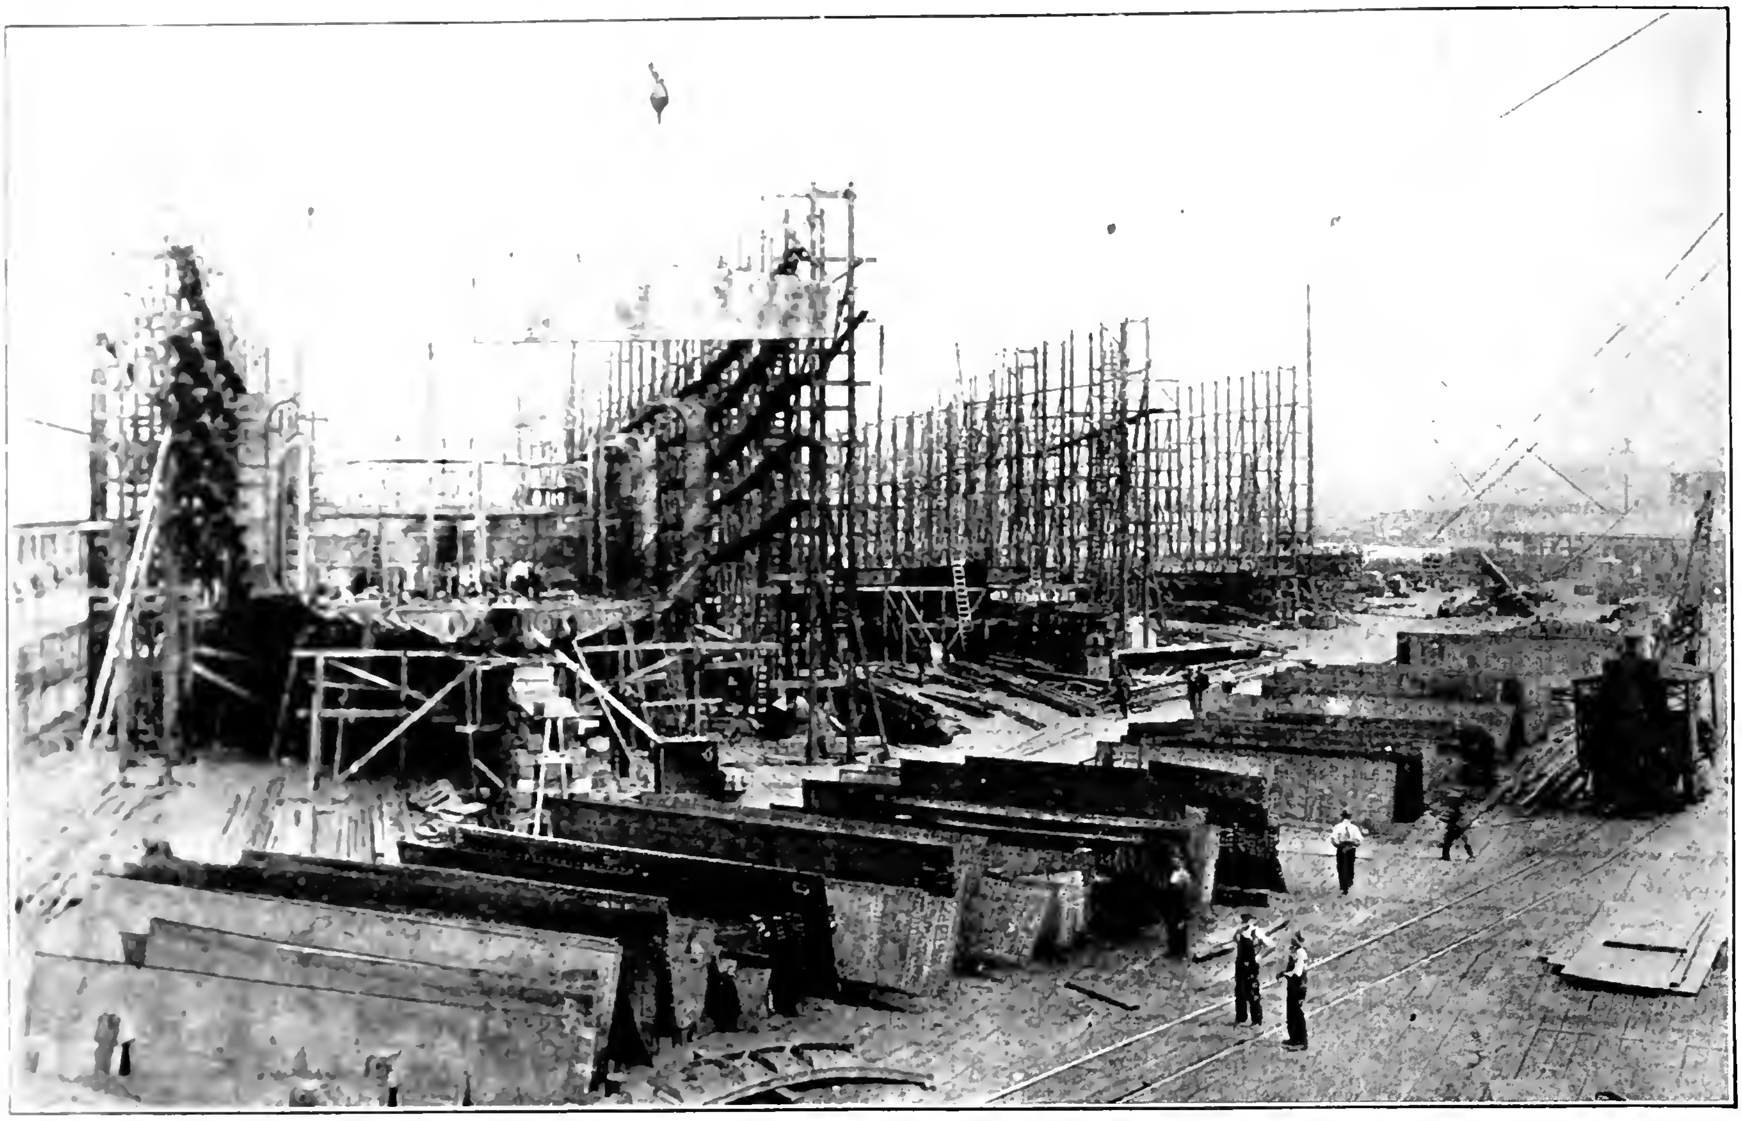

FIG. 2. TWO CABLEWAYS PER SHIPWAY USUALLY WORKED TOGETHER IN PLACING STEEL

main cables parted. This occurred, however, within a few weeks after the system had been installed, and is regarded as a failure to exercise sufficient care in design and inspection, rather than as a reflection on the cableway system.

The masts used vary from 105 to 125 ft. in height. The bow masts are usually 5 ft. higher than the stern masts, so loads are handled downgrade. The taller masts are conceded to have advantages over the 100- and 105-ft. masts which probably more than offset the additional cost. The 115-ft. masts are 3 to 4 ft. in diameter at the bottom and about 2½ ft. at the top. They cost at tidewater in Portland and Seattle between $300 and $400 apiece. Steel masts for this purpose have not been used in Pacific coast yards. The main cables are almost all 1¾ in. in diameter. A notable exception to this is the system of the Northwest Steel Co. at Portland; this yard, which has been in operation for two years, uses a 1⅜-in. main cable of six strands, with hemp core. When one cableway in this plant had built three 8800-ton vessels, in each of which approximately 2800 tons of steel had been placed, the main cable was found to have been flattened somewhat on top. It was then replaced with a line of the same size having a steel core, thus increasing the strength without necessitating a change of trolleys. These stronger cables last for about six boats, after which the mechanical wear shown warrants their replacement. The ½-in. hauling cables average only three to four boats.

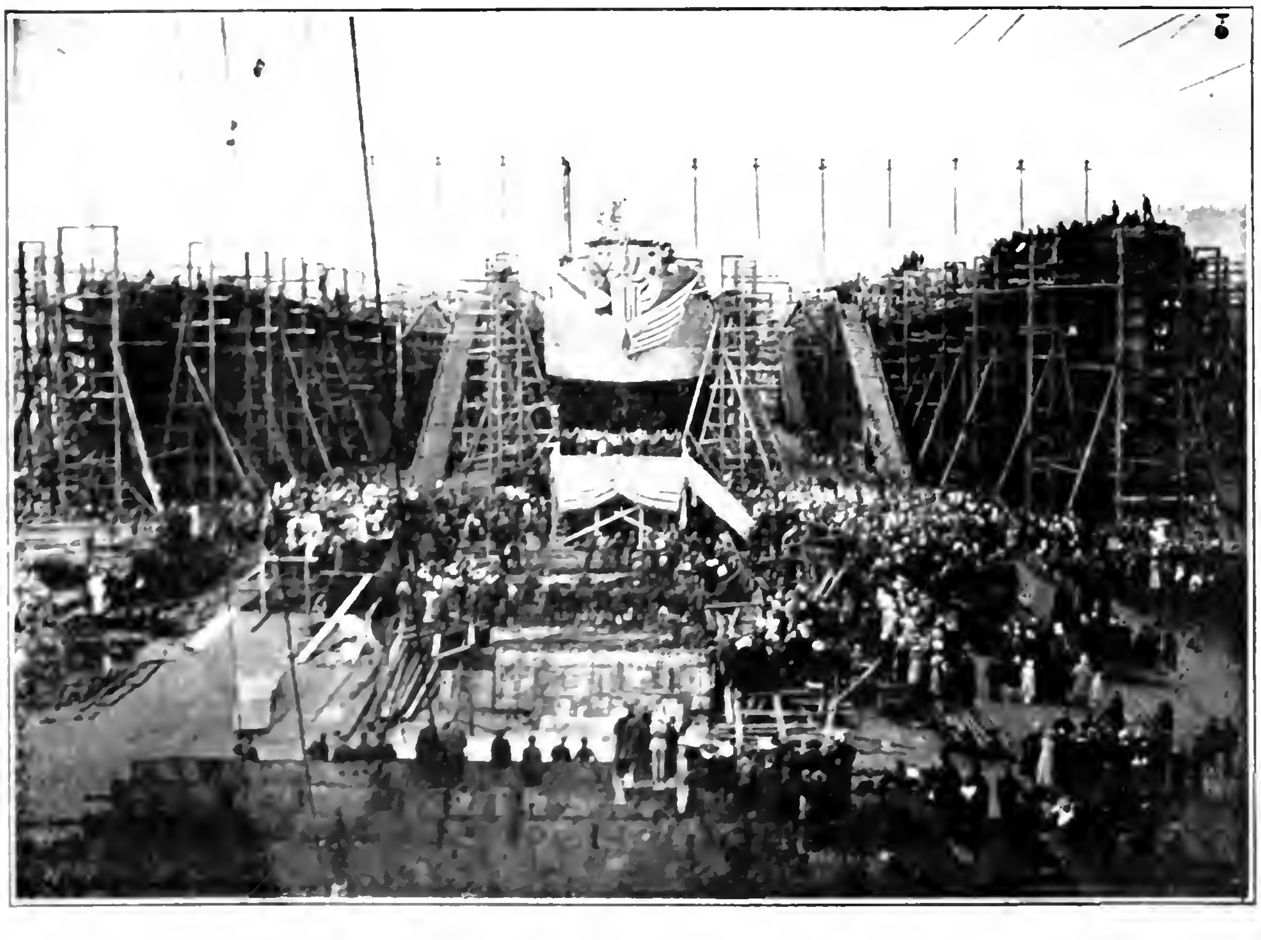

FIG. 3. CABLEWAY SYSTEM SEEN FROM WINCHMAN'S HOUSE ON PLATE SHOP, TODD YARD, TACOMA

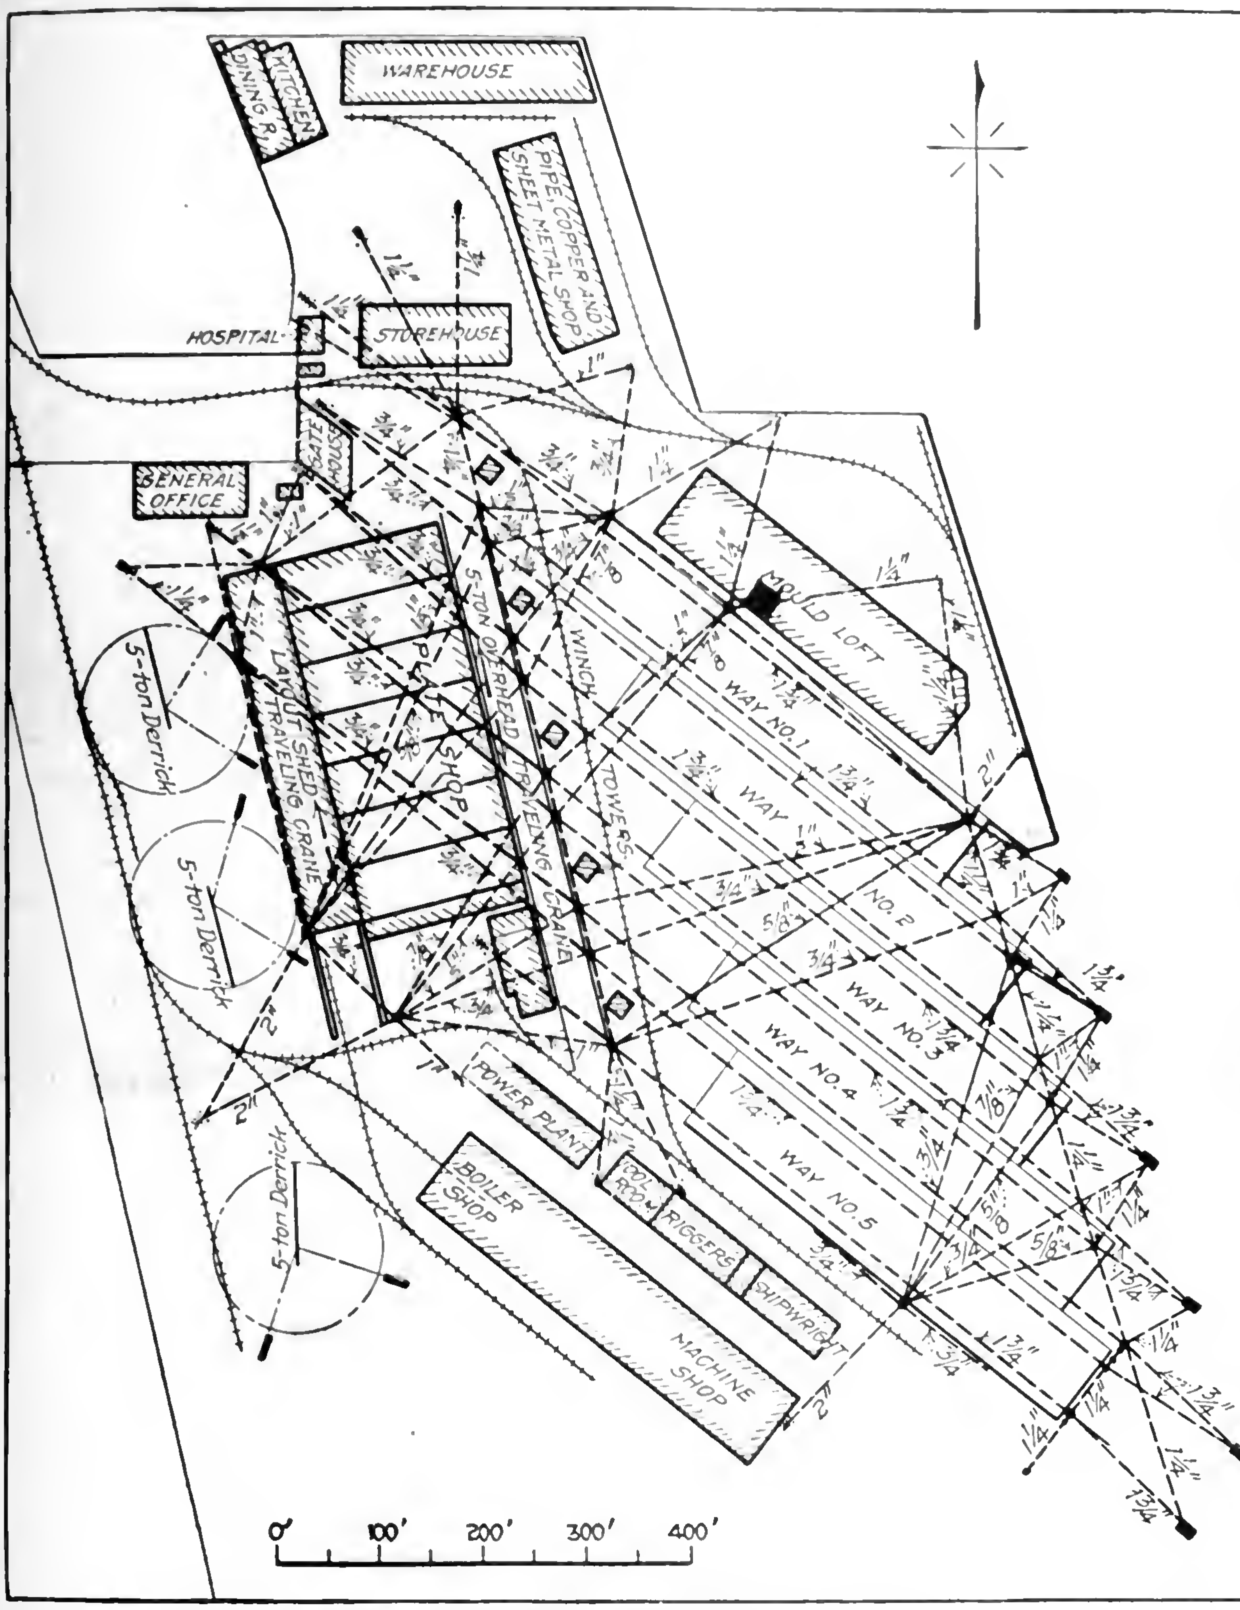

FIG. 4. PLAN OF SKEW CABLEWAY SYSTEM, SEATTLE-NORTH PACIFIC SHIPBUILDING COMPANY

Operating Control—An important operating feature of the cableway design is the location of the hoist controls. Most of the yards deem it essential for best results to have the operator where he has an unobstructed view of the work. Where there are no buildings located so that it would be convenient to set the hoist controls upon them, towers are built specially for this purpose. Most of the yards have the winches also in the towers; the cables run first to the ground and thence to and up the masts. At the Skinner & Eddy plant the winchmen are set on the ground. They are provided, however, with a telephone head-set with which they can hear a bell located well down the way, and which a signalman rings to indicate just how the load is to be moved.

Where a cableway is provided on either side of the way, towers are set on the center line, near the bow masts. Except for one steam-winch plant at Portland the hoists are all electrically operated, a separate motor and pair of drums being provided for each cableway. Where the two hoists for each way are mounted side by side, a single operator only is required. The two hoists in each tower are frequently so arranged that their traveling frictions can be locked together and the two trolleys operated at uniform speed, controlled by a single controller and brake. In this way one operator, handling both lines, can utilize the combined capacity of the two on a single lift or can separate them for independent operation.

Ordinarily, the two hooks are coupled together by a header cable about 14 ft. long, and the carriers are operated together for every load, to give the greatest precision in placing. It is generally reported by yard foremen that the two lines operating as one can deliver the material faster than it can be placed in the ship. The trolley speeds range up to 250 ft. per minute. In one of the Northwest plants the eight-hour operating record stands at 110 lifts with travel averaging 300 feet. The motors range up to 25 or 30 hp. and loads up to four or five tons can be handled by a pair of hooks combined.

Not all of the yards, however, use two cables per way. Some are using three and some four. In these cases one stern mast (on the way center line) has to be removed before each launching. A crew of six men does this in about half a day, without disturbing the other masts, thus leaving the two outer lines free to operate separately or jointly. Where four cables are used the central mast carries two cables separated by a spreader near the mast head. With the four-cable arrangement two winchmen are used in each tower, each man operating two carriers that can be coupled together or operated singly; all four hooks could be combined, but it is seldom done. Where three lines are used the two outer ones are usually worked together, the central cable being used for lighter loads. This three-cable system is commonly installed where oil tankers are to be built, because of the amount of material to go into the holds.

In the Ames yard at Seattle the towers are 125 ft. high and contain only winch controls, the winches themselves being set on the ground at the base of the masts. Under this plan the winches cannot be coupled together, and a separate operator is required for each carrier. Some of the shipways have three cableways each, and three operators are required in each tower constantly.

Although this is expensive in labor cost, it has the advantage of making the winches very accessible, and delays from breakdowns and maintenance costs are reduced.

In the Seattle North Pacific yard, the plan of which is shown, the ways had to be set at an acute angle to provide sufficient space for launching. This called for a more elaborate system of cross-guying than is usually provided, and required high masts so that the cross-cables could clear the main cables. The superintendent in this yard reports that the system is very easy to maintain, and riggers are always available when needed. The responsibility for the maintenance of the cableways is placed upon one man, who is expected to inspect personally all parts of the system as frequently as necessary.

The masts in this yard are particularly fine sticks, ranging up to 4½ ft. in diameter. They rest on a cluster of piles, on top of which a nest of timbers was built up for the foot of the mast. When the J. F. Duthie plant was built, masts of the desired height could not be obtained promptly for all the ways. Shorter and lighter masts were therefore used at the bow, and footings were built up above the planking 8 to 12 ft., as required to give them the desired height. These masts were strengthened by wrought-iron truss rods with turnbuckles for drawing them taut against struts placed at about mid-height.

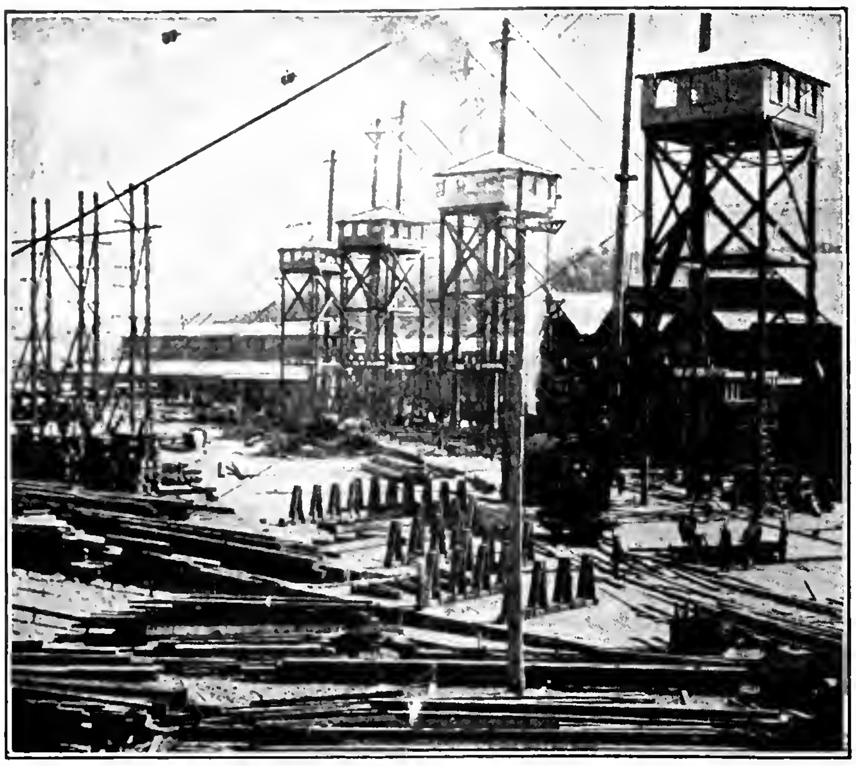

FIG. 5. CABLEWAY WINCHES IN CONTROL TOWERS, SEATTLE-NORTH PACIFIC SHIPBUILDING COMPANY

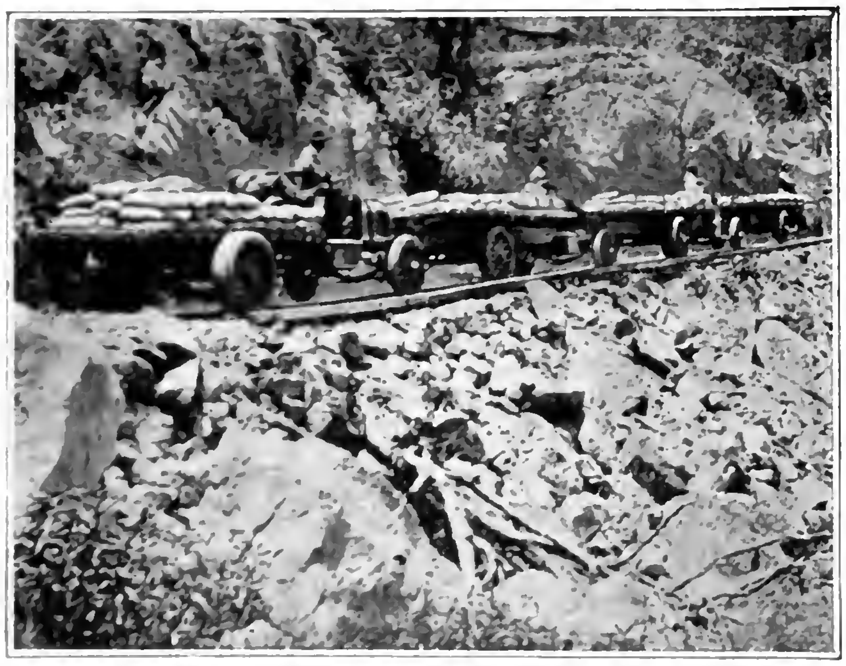
Motor Trucks Operate Over Steep Grades on Hetch Hetchy Project

TRANSPORTING of materials to the Eleanor Dam on the Hetch Hetchy project in California was an important factor in the construction problem. A fleet of motor trucks was used to haul materials over the 12 miles from the terminus of the Hetch Hetchy R.R., and was found to be entirely satisfactory, despite the rough trip involved. The costs worked out at about $10 per ton.



HAULING CEMENT ON THE LONG 15 PER CENT GRADE

A 68-mile railroad built by the city terminates at the Hetch Hetchy dam site, and from this point a wagon road had to be built to the Lake Eleanor site. In order to get out of the valley, it was necessary to locate the road with continuous grades ranging up to 15% for the first three miles. In this distance there are seven very sharp turns, which usually require a truck to reverse about three times in order to get around. Making these turns wider would have greatly increased the cost, because of the uniform slope of the hill along which the grade is located. Beyond this rise the grades and alignments are much better. The entire road was built in the three months between Apr. 20 and July 20, 1917, at a cost of about $6000 per mile.

In the hauling contract the basis was a 70-sack load of cement, and the price was $35 per round trip of the truck. It was found, however, that by special agreement with the drivers each truck could make two trips a day. From a rough check on costs kept by the city it is estimated that the contractors' net profit has been about $5 per day per truck. There were eight trucks in the fleet and sixteen drivers. Most of the trucks were rated at 3½ or 4 tons capacity.

The work is being carried out by the City of San Francisco under the direction of M. M. O'Shaughnessy, city engineer.

Regulates Bottled-Water Traffic

Two hundred dollars fine is the penalty which Florida purveyors of bottled water must pay if they do not follow the stringent regulatory measures of the State Board of Health. First, there must be furnished to the board on Jan. 10 of each year the name of the water sold and the exact location from which it is obtained; chemical and bacterial analyses, or formulas, if the waters are manufactured. A permit must be obtained, and the board may revoke this if the water "appears to it to be a menace to health." Two bottled samples as prepared for sale are to be supplied to the board for laboratory examination every two months.

Engineering Educators' Opinions Reflect Past and Predict Future Conditions

Now that the Students' Army Training Corps has been disbanded and educators are actively engaged with the problems of the transition period of readjustment to peace conditions, the opportunity is being seized to initiate changes of far-reaching importance. In order to reflect these changes and present the trend of opinion among engineering educators "Engineering News-Record" sent to the deans of various engineering colleges a communication containing the following questions:

1. What was the influence of the S. A. T. C. upon the engineering colleges? Did the experience affect the educator's viewpoint, and if so, how?

2. Will the return to peace mean a return to pre-war courses without essential modification? If not, just what changes are contemplated? What considerations determined these changes?

3. Have you embodied in your plans for after-war courses any of the suggested solutions brought out by Dr. Mann in his "Study of Engineering Education"? (See "Engineering News-Record" of Oct. 24, p. 782). If so, just how are they to be applied?

4. What is your estimate of the new needs and opportunities in engineering education developed as a result of the war? How can they best be met?

The replies which are here presented indicate the wide divergence of opinion which still persists through the war experience It is hoped that practicing engineers will also coöperate in this vital matter of developing the best possible future for engineering education, and send us definite suggestions, in the nature of specifications for the desired graduates, in the light of war experience.—EDITOR.

Illinois To Make Readjustments, but No Permanent Changes Now

BY C. R. RICHARDS
Dean and Director of the College of Engineering, University of Illinois, Urbana, Ill.

IN REPLY to your letter asking my opinion concerning certain matters in connection with engineering education, I will undertake to answer your definite questions as follows:

1. If the war had continued for a year or two longer, it is possible that the organization of the S. A. T. C. would have had a decided influence on educational institutions. The signing of the armistice so soon after the organization of this corps has interrupted this educational experiment, to its detriment. It does not seem possible to estimate at this time the influence of this organization on the engineering colleges, although I have no doubt that in those institutions which undertook the instruction of mechanics and tenchnicians there will be an increased appreciation of the possibilities for intensive training of men for highly specialized work.

2. For the remainder of the current academic year, the College of Engineering of the University of Illinois has been compelled to make certain readjustments in existing curricula to permit the students to continue without being seriously penalized as a result of their experience with the S. A. T. C. Very little real work has been possible during the first quarter, and we have found it necessary to take this into account in outlining our program of studies for the remainder of the present academic year. At the present time, no permanent changes in the curricula are contemplated or are considered necessary or desirable. This college is alive to the need to keep in touch with changing conditions, but it does not feel justified as yet in making any revolutionary changes in its work.

3. During the past three months, as a result of the serious interruption to our work, the more or less complete disorganization of the university and a reduced staff of instructors, together with the extraordinary demands made upon the staff, we have had no time to give serious consideration to Dr. Mann's report. This report is to receive the careful consideration of the faculty during the year, and I have no doubt we shall make such use of the suggestions which Dr. Mann has made as may seem wise and practicable under existing conditions. I may frankly say that it would seem to me to be very unwise for any technical school to effect a complete revision of its curricula as a result of Dr. Mann's report, without giving the matter very careful thought and study.

4. In my opinion, there will be a greatly increased enrollment of students in the technical schools of America as a result of the war, for the importance to the nation of men with technical and scientific training has been demonstrated. It seems to me, therefore, that the industries should show an increased appreciation of properly trained men and of scientific research. Both in Europe and in America the need for research to enable the industries of these countries to meet new conditions which have arisen has been so strikingly shown that I anticipate that more attention will be given in the future to research in the colleges and in the indus-

tries. I have no doubt that there will be some disposition, as a result of the experience with vocational training in the Army, to assume that short courses of intensive training may be profitably substituted for the longer and more complete curricula of instruction given in the engineering schools. While I believe that vocational education should be stimulated in every possible way, I should consider that the substitution of such training for the broader training which the American colleges have developed would be little short of a calamity.

Rensselaer Polytechnic to Make no Radical Changes

By Palmer C. Ricketts
President, Rensselaer Polytechnic Institute, Troy, N. Y.

Replying to your four questions on the war education experience at Rensselaer Polytechnic Institute, I would give the following opinions:

1. The S. A. T. C. did not have a fair trial at this institution. The influenza affected the work seriously, and after the influenza came diphtheria. Many members of the Corps lost weeks of time. I hoped that the Government would be able to continue the corps in existence until June, in order that this form of military training at our educational institutions might have a fair trial. I hoped this in spite of the serious difficulties we had had, from an educational point of view, during the three months just ended. Since this experiment could not be tried in this way, I am at a loss what to say regarding military training in institutions of this character. Last year we had a paid instructor who gave military drill three hours a week to the students who elected to take it. We may have some such arrangement in the future. I do not expect that we shall establish a unit of the Reserve Officers' Training Corps here. What we want just now is a rest for some months before we decide this matter.

2. The return to peace will mean a return to pre-war courses without essential modification. We shall give five weeks' review here, beginning Jan. 2, and we shall give our second term as usual.

3. We have not embodied in our after-war courses any of the suggested solutions brought out by Dr. Mann.

4. We all know that the war has shown very forcibly the value of an engineering education to many persons who never before gave the matter much thought. Increased attendance at the engineering schools may result. It will be our business constantly to improve our engineering courses in the future, as they have been constantly improved from year to year in the past, but we certainly do not expect to make any radical changes in our methods.

General Effects on Middle West Universities Are Profound

By M. E. Cooley
Dean of the College of Engineering, University of Michigan, Ann Arbor, Mich.

Having been away from Ann Arbor since the middle of October, in charge of collegiate training of the S. A. T. C. at the universities of Illinois, Wisconsin and Michigan, I can only make a general statement in reply to your questionnaire. Engineering educators probably have the same opinion as other college teachers, the general verdict being that the S. A. T. C. was a failure, and that it is a pleasure to return to the old status. My own belief is that the S. A. T. C. was a pronounced success, considering it as a gigantic enterprise in operation less than 12 weeks and seriously handicapped by influenza. Another 60 days would have seen smooth sailing.

I further believe that educational institutions were stirred to their foundations, and will never return completely to the old status. Something was needed to jar them from their complacency, and the S. A. T. C. did it. Teachers have had an opportunity to adapt their courses to immediate practical needs, which should result in greater directness in the courses of the future. More important is the changed attitude of people toward the kinds of education desired. I hope and pray military training may be desired, for its discipline and leveling effect. What the country needs is escape from slavery to the almighty dollar, and education should strive to impart another ideal—such as responsible citizenship, for example.

Engineering education should be broadened and not narrowed; the biggest problems of the world today require men of vision, and the engineer of today is nearsighted. He can do one specific thing splendidly, and usually only one.

The above general statements answer your fourth question. In reply to the other three I would say: (1) The effect of experience with the S. A. T. C. is not yet crystallized, but the educators' viewpoint is undoubtedly changed; (2) yes, but not permanently; (3) no changes based upon Dr. Mann's report are yet proposed here.

Wisconsin to Return to Pre-War Courses

By F. E. Turneaure
Dean of the College of Mechanics and Engineering, University of Wisconsin, Madison, Wis.

Referring to your request for opinions regarding the effects of experience with the Students' Army Training Corps, I have the following to suggest:

1. The S. A. T. C. has, during the past quarter, interfered very seriously with the academic work of the College of Engineering at this institution, but it is generally conceded that the work of the engineering students has been better than that of the students of the College of Liberal Arts. This is probably due to the fact that the engineering students were pursuing studies more in accordance with the work they came to do than was the case with the other students. It is the judgment of the engineering faculty, I believe, that the lack of success of this experiment, from the academic point of view, was due partly to accidental circumstances and partly to the nature of the system itself—a combination of military and civilian life under two separate heads. The S. A. T. C. had a very considerable effect on the attendance, the number of freshman students being more than twice as large as the normal. Many of these will not return after Christmas.

2. With the demobilization of the S. A. T. C., the college will promptly return to its pre-war basis, without essential modification for the present year.

3. Due largely to the extra labor involved in the S. A. T. C. work, there has not been time for serious consideration of the suggestions contained in the report of Dr. Mann. This report will, however, receive careful consideration during the year.

4. I believe that the needs and opportunities which will be developed in the near future will not be radically different from those in the past, although they will doubtless differ considerably in degree. It seems apparent that engineering graduates have thoroughly made good in all kinds of war activities, and I do not anticipate any radical changes in engineering education. It is probable, however, that additional emphasis will be laid upon humanistic studies such as economics and sociology.

Missouri Sees Change in Spirit of Presentation of Courses

By E. J. McCaustland

Dean and Director of the School of Engineering, University of Missouri, Columbia, Mo.

Answering your questionnaire in categorical detail, I would say:

1. On the whole, I believe the influence of the S. A. T. C. upon the engineering colleges was good. While a great deal of friction developed, due to an overlapping of authority, yet the results were, on the whole, helpful. The experience has affected the educators' viewpoint in regard to the possibility of holding the student up to a higher standard of accomplishment than has ordinarily been done in the colleges. This result, however, can only be accomplished through special effort on the part of the teacher, and I believe that all wideawake teachers of engineering have come to appreciate their opportunities more fully from having observed at first-hand the effects of insistent demands on youth even though such demands come from young and inexperienced military instructors.

2. Whether the return to peace will mean a return to pre-war courses without essential modifications, is a crucial problem facing the engineering schools. For ourselves, we feel that the change most desirable is a change in the spirit of presentation rather than in the substance of the courses offered. We must show the student wherein he is rendering a service to the community and to the state by his more earnest attention to his preparation. Since the main motive actuating the members of the S. A. T. C. was the consciousness of making preparation for definite service as officers in the Army, we must show them that preparation for professional fitness will be as great a service to the state in times of peace as the other preparation would be in time of war.

3. We have not yet fully discussed the possibility of embodying in our courses some of the suggested solutions brought out by Dr. Mann in his study of engineering education, but our men are examining this report very carefully, and I believe we shall feel the reaction from such study in the coming term's work.

4. Two points will be emphasized in future engineering education, as a result of the war. First, the arousing of more interest in and furnishing greater opportunity for research. In general, research is sadly neglected in the engineering schools or restricted to very high-class work. I believe that recent experiences indicate that we need to develop a wider interest in research, so that latent research ability may be brought to the front and receive an opportunity to develop. Second, more than ever before there has been impressed upon us the supreme value of a thorough training in the fundamentals of science and in covering a broad field, to serve as a basis for later specialization. I think both of these points can be met only gradually as the point of view of engineering educators begins to concentrate more and more on these needs.

Curriculum Changed at Tufts College

By Gardner C. Anthony

Dean of the College of Engineering, Tufts College, Mass.

In the engineering school of Tufts college a most interesting and somewhat radical departure from previous curricula will be made. It is in line with the suggestions made by the Joint Committee on Engineering Education (Dr. Mann's report). Some of the recommendations made by this committee are not entirely new to the Tufts Engineering School, and the new curriculum which is offered to the freshmen already entered, and those about to enter Jan. 2, 1919, will embody details which have been tested before, but never properly correlated.

During the past year intensive courses were tried out for freshmen, and it was observed that high-grade work and enthusiastic application to studies can be obtained by giving them courses of a laboratory character which shall serve as introductory to the special courses leading to the several degrees, and accompanying such courses by such mathematics and physics as may be necessary for the logical development of the subjects.

Very recently, too, a readjustment of the five courses in engineering has made it possible so to combine them as to reduce the number to three; namely (1) civil engineering; (2) mechanical and electrical engineering, and (3) chemical engineering. Furthermore, the faculty had already postponed some of the more advanced mathematics to the junior year and had proposed postponing some of the physics until a more appreciative period of student development.

On registering for the next term the freshmen engineers will choose an introductory course in one of the three engineering departments. This will require nearly one-half of the total time allotted for study. In addition to this major course, the student will pursue but two other studies, which in the second term will be English and mathematics, and in the third term English and graphics.

By this plan, the attention of the student will be confined to but three, or at the most four, subjects, which will be properly correlated and pursued intensively. One of these, the main introductory course, is designed to give a proper perspective of the relation of the professional courses to the theoretical studies.

In the second year, each of the three engineering departments will offer a second and more advanced course accompanied by the necessary mathematics, physics and other subjects, which latter will be taught as a part of the departmental course. But the student

must elect an introductory course in another department; thus, it is designed to require introductory courses in at least two engineering departments, insuring a broader type of education than can possibly be obtained by specializing in one department.

This plan will postpone the main course in physics until the junior year and the most advanced mathematics until the senior year. It will also admit of considerable more election in the junior and senior years than has previously been possible. The modern language course will be conducted with special reference to the study of the commercial relations between the United States and foreign countries. To this end prominence will be given to the study of Spanish.

[*Several have replied that they felt it was too early to make definite statements on the questions raised, as they are still considering changes and studying Dr. Mann's report. Other replies will be printed in a later issue.*—EDITOR.]

Beam Deflections Under Distributed or Concentrated Loading

New Algebraic Method Proposed for Cases Usually Solved by Graphical Calculation Gives Accurate Results

BY J. B. KOMMERS
Madison, Wisconsin

DEFLECTIONS of beams can be calculated by an algebraic method that compares favorably with the graphical method both in time required and in accuracy. It is intended for use in those cases of combinations of uniform and concentrated loads for which the ordinary algebraic method would become very long and tedious. Simple beams, cantilever beams, beams fixed at one end and supported at the other, and beams fixed at both ends, will be discussed.

Suppose a simple beam has upon it a concentrated load, P. When P is at the center of the span the maximum deflection occurs at the center; when P is at the right support the maximum deflection occurs $0.577L$ from the left support. This means that no matter where the concentrated load is placed on the beam its maximum deflection will always be very near the center of the span, and therefore that the midspan deflection will be practically equal to the maximum deflection. This latter fact is utilized as the basis of the new method.

DEFLECTIONS OF SIMPLE BEAMS

In Fig. 1 the maximum deflection due to the two concentrated loads is to be determined. According to Maxwell's theorem, the deflection produced at the center, O, by the load at A equals the deflection produced at A by the same load placed at O. Therefore, place the 7000-lb. load at O, calculate the deflection it produces at A; place the 8000-lb. load at O and calculate the deflection it produces at B. The sum of these two deflections will be the deflection that the two loads at A and B produce at O and, as shown above, a very good approximation to the maximum deflection.

The deflection which a central load P on a simple beam produces at a point distant x from the nearest support is,

$$\text{Defl.} = \frac{Px^3}{12EI} - \frac{PL^2x}{16EI} \qquad (1)$$

Applying this equation to the case of Fig. 1, in order to get the maximum deflection by the method outlined,

$$\text{Max. Defl.} = \frac{7000 \times 60^3}{12EI} - \frac{7000 \times 180^2 \times 60}{16EI} + \frac{8000 \times 36^3}{12EI} - \frac{8000 \times 180^2 \times 36}{16EI} = -0.1971 \text{ inches.}$$

As a check upon this method, the correct maximum deflection was calculated; it was found to be 0.1970 inches.

If the beam in Fig. 1 is loaded with 13,000 lb. at A and 2000 lb. at B, the approximate result is 0.50% too small.

If the beam carries distributed loads on parts of its length as well as concentrated loads, the method is applied by breaking the distributed load into several sections and replacing these by concentrated loads at their centers of gravity. In Fig. 2 is shown a uniformly loaded beam. Such a symmetrical case would not require special treatment, but is chosen here to illustrate the method. Consider the load divided into four parts; then calculation by the approximate method gives 0.2525 in., while the exact value of the deflection is 0.2462. Thus, the approximate result is 2.56% too large. The load can easily be broken up into six parts instead of four, and then the approximation will be only 1.21% too large, a precision comparing favorably with that of graphical work.

If the beam in Fig. 2 is loaded over the left half of the span with a uniform load of 21,000 lb., and this is then broken up into three sections, the approximate method gives a result which is only 0.44% too large.

DISTRIBUTED LOADS ON CANTILEVER BEAMS

In a cantilever beam any load will produce its maximum deflection at the free end, so that the method described involves no approximation for concentrated loads. Distributed loads are broken up into sections, as before, and replaced by concentrated loads. The deflection produced at the free end of a cantilever by a load at A, Fig. 3, is

$$\text{Defl.} = -\frac{Pb^2}{6EI}(3a + 2b) \qquad (2)$$

Applied to the numerical case shown in Fig. 4 it gives 1.438 in. (correct deflection 1.443), so that the approximate result in this case is 0.35% too small.

If the same beam is loaded with 7500 lb. uniformly distributed on the half next to the fixed end, and this load is considered broken up into two sections for applying the approximate method, the result is 5.2% too small. Greater accuracy may be obtained by breaking the load into a larger number of sections; if four sections are used the deflection at the free end is only 1.5% too small.

It should also be noted that when there are several loads on the beam the uniform load near the fixed end produces only a small part of the total deflection. In the case of a uniform load over the whole beam, the half next to the fixed end produces only 14.6% of the total deflection.

BEAMS FIXED AT ONE END

Fig. 5 shows the case of a beam fixed at one end and supported at the other. For the case shown the absolute maximum deflection occurs under the load when $a = 0.414L$. When $a = 0.95L$ the maximum deflection oc-

curs at a point $0.568L$ from the left support. When $a = 0.05L$ the maximum deflection occurs at a point $0.332L$ from the left support. It will be assumed that for all ordinary combinations of loading the maximum deflection will occur at $0.414L$.

In order to determine the maximum deflection, it is necessary to determine the reaction, R, at the support. To do this, treat all loads as though on a cantilever beam, and determine the deflection they would cause at the left end. The deflection due to R must be exactly equal to the deflection of the loads. Therefore, solve for R from the following formula:

$$\frac{RL^3}{3EI} = \text{Deflection due to the loads} \qquad (3)$$

The deflections due to the loads will be found, of course, by the approximate method for cantilever beams heretofore described.

When R is known, the downward deflection caused by the loads at $0.414L$ is calculated, and from it is subtracted the upward deflection caused by R at $0.414L$. The difference will be a good approximation of the correct maximum deflection.

The formulas to be used for calculating the deflection at A in Fig. 6 are as follows:

$$\left.\begin{array}{l}\text{Due to}\\ \text{Load to}\\ \text{left of A}\end{array}\right\} \text{Defl.} = -\frac{P_1b^2}{6EI}(3a + 2b) \qquad (4)$$

$$\left.\begin{array}{l}\text{Due to}\\ \text{Load to}\\ \text{right of A}\end{array}\right\} \text{Defl.} = -\frac{P_2d^2}{6EI}(3c + 2d) \qquad (5)$$

$$\left.\begin{array}{l}\text{Do to}\\ \text{Reaction}\end{array}\right\} \text{Defl.} = \frac{0.1382RL^3}{EI} \qquad (6)$$

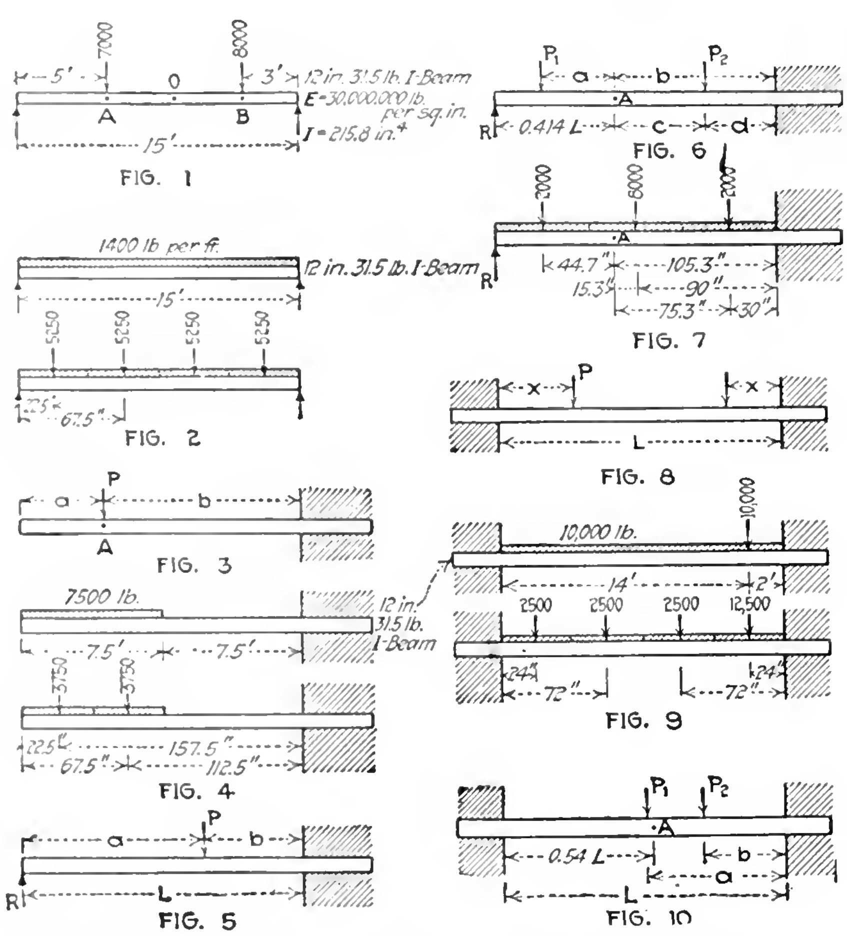
The method will be illustrated by working a problem which can be easily checked. Fig. 7 shows the loading. The deflection at the left due to the loads is 1.2262 in. Then $R \times 180^3/3EI = 1.2262$, and $R = 4087$ lb. Using this value, the deflection at A due to R is found from formula (6) to be 0.5088. By formulas (4) and (6) the deflection at A due to the loads is computed as 0.5865 in. Subtracting, the net deflection at A is 0.0777 in. This result is 1.27% too small.

If the beam in Fig. 7 is loaded with a uniform load of 15,000 lb. on the left half of the span, and this is then broken up into three sections, the approximate result is 1.64% too large. If the same load is placed on the right half of the span the approximate result is 4.02% too small. Thus, for uniform load near the fixed end the degree of accuracy is not as great as for the same load near the left support.

Investigation shows that for the load near the left support increased accuracy can be had by breaking up the load into more than three sections. For the uniform load near the fixed end, however, the error is due to the fact that the maximum deflection occurs near the center of the beam instead of at $0.414L$ as assumed. It is recommended, therefore, that for those cases in which all the loads, both uniform and concentrated, lie to the right of the center of the beam, the deflections be calculated at $0.47L$ instead of $0.414L$. In this case the deflection at $0.47L$ due to the reaction is

$$\text{Defl.} = \frac{0.1155RL^3}{EI} \qquad (7)$$

If in the case of the beam loaded on the right half of the span the deflections are calculated at $0.47L$, the result is only 0.17% too small.



BEAMS UNDER DIFFERENT CONDITIONS OF SUPPORT AND LOADING ADAPTED TO ALGEBRAIC CALCULATION OF DEFLECTIONS

Fig. 8 shows a beam which is fixed at both ends. The absolute maximum deflection for a concentrated load will occur under the load at the center of the beam. Even if the load is distant from the right support only $0.05L$, the maximum deflection will occur at $0.653L$, or still quite near the center. This, of course, is an extreme case, and as in the case of simple beams it will be assumed that the maximum deflection occurs at the center. The deflection which a load P, in Fig. 8, causes at the center is given by the formula

$$\text{Defl.} = -\frac{PLx^2}{16EI} + \frac{Px^3}{12EI} \qquad (8)$$

The sum of the deflections found in this way will equal the maximum deflection.

Fig. 9 shows a numerical case with the concentrated load quite far to one side of the center. The approximate result in this case is 0.69% too small.

When the beam in Fig. 9 is loaded with a uniform load of 15,000 lb. over the right half of the span, and this is then broken up into three parts, the approximate method gives a result which is 2.85% too small. Investigation shows that the error is due to the fact that the maximum deflection falls to the right of the center instead of at the center, as assumed. It is recommended, therefore, that for those cases in which the loads, both uniform and concentrated, are all on the right side of the center of the beam, the deflections be calculated at a point $0.54L$ from the left end. For this purpose two formulas are necessary. The deflection at A, Fig. 10, is,

$$\left.\begin{array}{l}\text{Due to}\\ \text{Load to}\\ \text{right of A}\end{array}\right\} \text{Defl.} = -\frac{0.06707}{EI}P_2b^2L + \frac{0.09332}{EI}P_2b^3 \qquad (9)$$

$$\left.\begin{array}{l}\text{Due to}\\ \text{Load to}\\ \text{left of A}\end{array}\right\} \begin{array}{l}\text{Defl.} = -\dfrac{0.06707}{EI}P_1a^2L + \dfrac{0.09332}{EI}P_1a^3\\ \qquad\qquad -\dfrac{P_1}{6EI}(a - 0.46L)^3\end{array} \qquad (10)$$

When the left half of the beam is loaded the distances a

and *b* in the formulas are measured from the left end of the beam.

When these formulas are applied to the beam shown in Fig. 9 with a uniform load of 15,000 lb. over the right half of the span, the result is only 0.17% too large.

The examples which have been worked show that the approximate method here suggested gives results which are at least as accurate as would be obtained by a graphical method. In the matter of speed in getting a solution, the method suggested will be found much superior in a great many problems.

Alaska Government Railway Nearly Half Completed

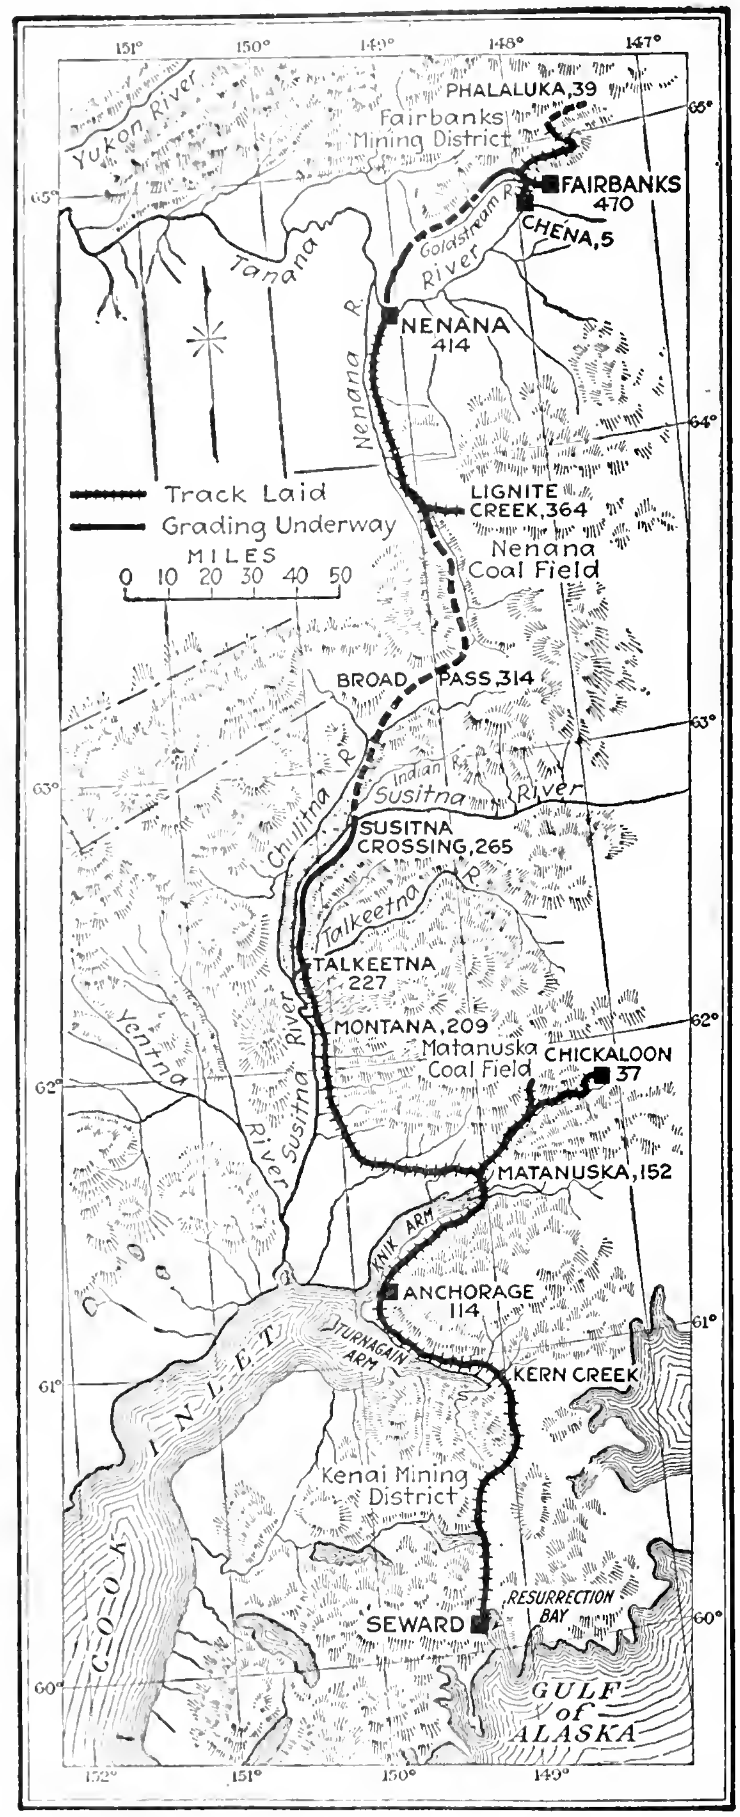
Main Line Open for 227 Miles, with 38-Mile Branch —Summit Elevation 2319 Feet—Grading By Stationmen

PROGRESS of construction on the Alaska railroad by the United States Government is called to attention by the recent completion of a 16-mile link which gives a 190-mile rail route from the Matanuska coal fields to tidewater at Seward, on the Gulf of Alaska. This was noted in *Engineering News-Record* of Sept. 26, p. 600. An extended article on the work up to 1916, by Thomas Riggs, Jr., formerly member of the Alaskan Engineering Commission and now Governor of Alaska, was published in *Engineering Record* of May 6, 1916, p. 600. The following brief review of this Government railway enterprise down to the present time is abstracted from a paper by Col. Frederick Mears, U. S. A., also formerly a member of the commission, in the *Alaska Railroad Record.* The route of the railway, with the parts completed and those under construction, is shown on the accompanying map.

An earlier commission, to study the transportation situation in Alaska, was appointed by the President in

GRADING ALONG SHORE OF TURNAGAIN ARM

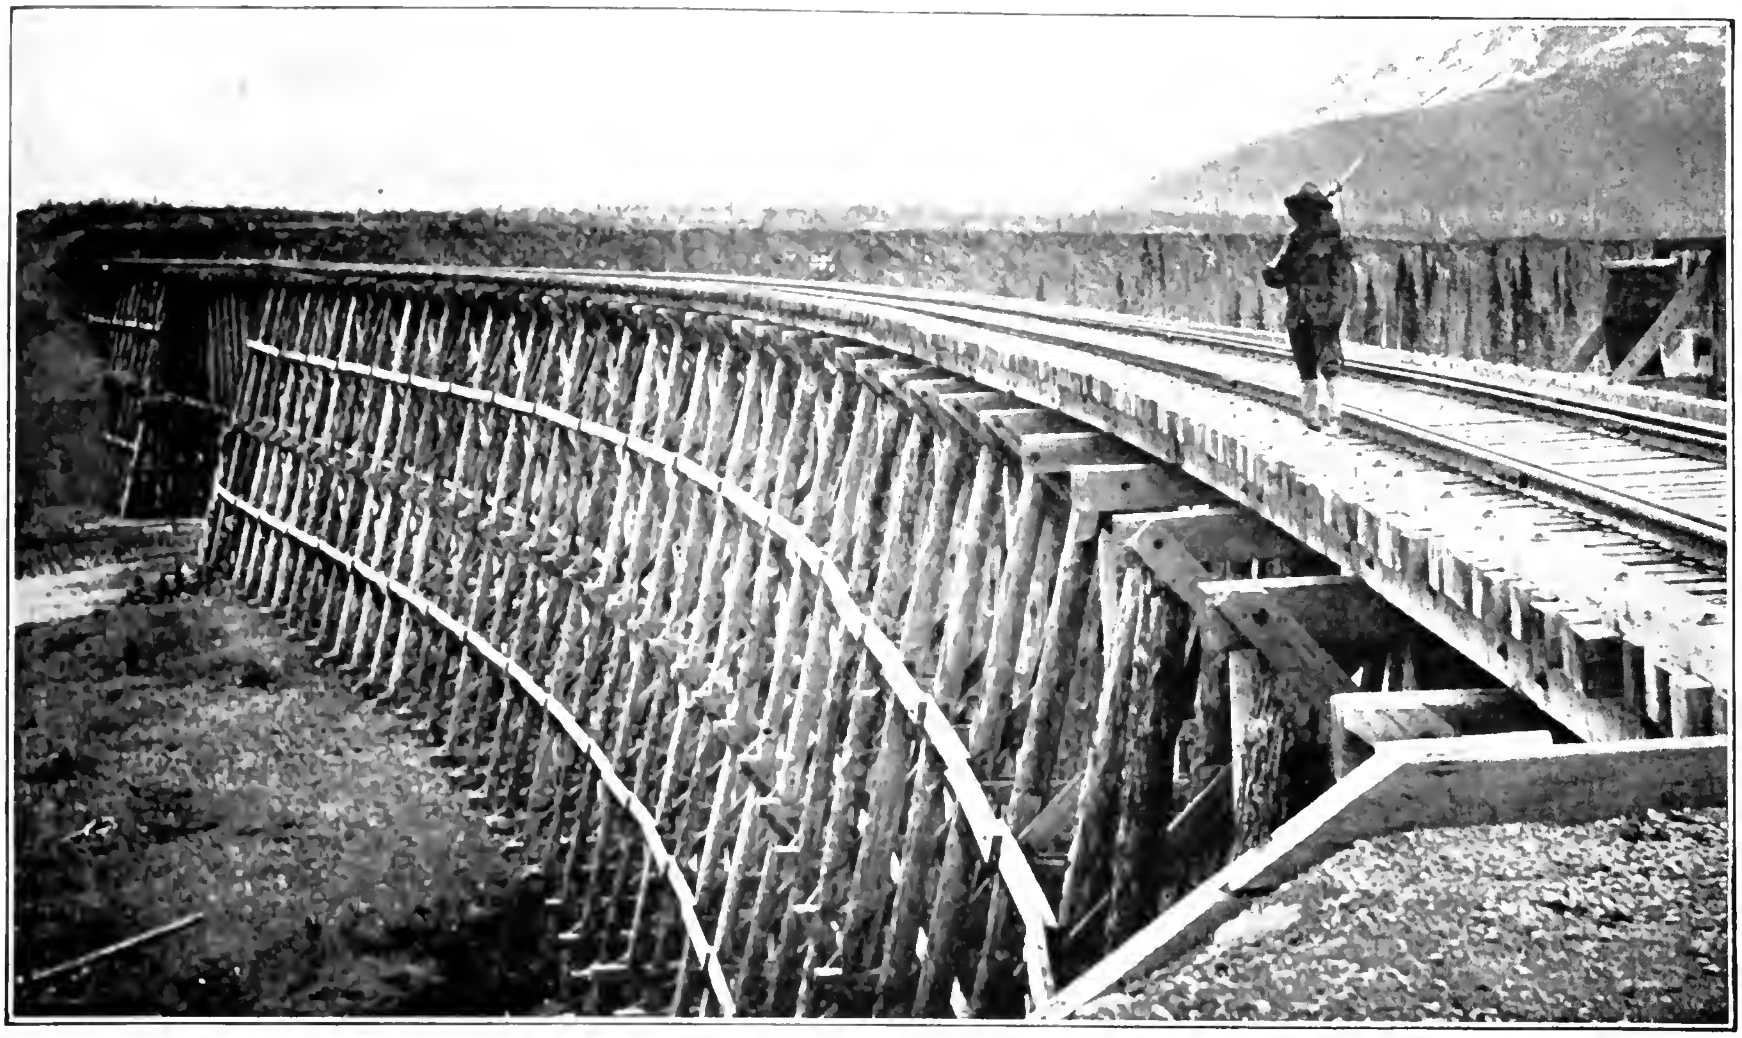
1913. This was headed by Maj. J. J. Morrow, Corps of Engineers, U. S. A., and its report was made in January, 1914. In March, 1914, Congress passed an act authorizing the President to construct and operate railways in Alaska and to acquire existing lines. The cost of the proposed system was estimated at $35,000,000.



MAP SHOWING TRACK LAID AND GRADING UNDER WAY

The present Alaskan Engineering Commission was appointed by President Wilson in the spring of 1914, with William C. Edes as chairman and chief engineer, to work under the general direction of the Secretary of the Interior. During the summer 13 parties were in the field, surveying mainly along two routes outlined by the first commission. Three bases of supplies were established: At Seward on the Gulf of Alaska (then the terminal of the Alaska Northern Ry.); at Anchorage, the head of ocean navigation in Cook Inlet, and at Fairbanks, the head of river navigation on the Tanana River. On the basis of the report made in 1915 the route from Seward to Fairbanks, 470 miles, was adopted, and in April the duties of the commission were extended to include the construction of the line.

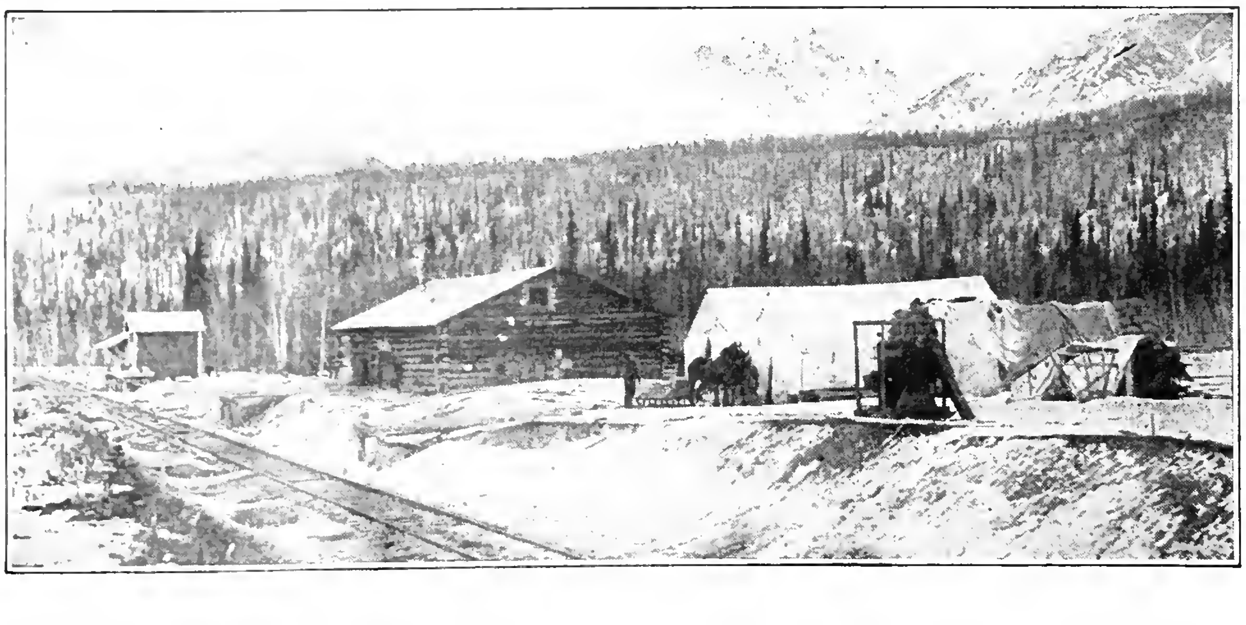
The Alaska Northern Ry. was a private enterprise,



TRESTLE WITH TIMBER TRUSS SPAN ON THE ALASKA RAILROAD—EAGLE RIVER, MILE 127½

started in 1904 but abandoned in 1909 with track laid for about 70 miles from Seward to Kern Creek, of which about 47 miles were operated in summer by gasoline cars. This line was purchased by the United States Government for $1,150,000, and its rehabilitation cost about $1,800,000. The location of the new Government line, north from Kern Creek, follows along the shores of arms of the sea to Anchorage and then to the mouth of the Matanuska River, whence a 38-mile branch extends to Chickaloon in the coal district. It then strikes west to the Susitna River, which it follows to mile 265, where it makes a crossing and then follows the Indian River and the forks of the Chulitna River. After crossing the Chulitna Pass and Broad Pass the line follows along the west bank of the Nenana River to mile 373, where it crosses and follows the east bank to the town of Nenana, at the junction with the Tanana River. It then crosses the latter river and follows the Goldstream valley to the terminus at Fairbanks.

A summit elevation of 2319 ft. is reached in Broad Pass (mile 314) on the continental divide. The max-



STATION BUILDINGS AT ANCHORAGE AND STATION BUILDINGS AND COMMISSARY AT KING RIVER, MATANUSKA BRANCH

imum grades are 2%, but on the greater part of the line they do not exceed 1%. Grading and clearing are done in short sections by stationmen, and Colonel Mears states that in view of the abnormal war conditions of high labor and material costs it is fortunate that the commission adopted this system instead of letting a general contract under the very different conditions of 1915.

Grading was classified as solid rock, loose rock, frozen material and common excavation. Clearing of right-of-way was let at $35 to $100 per acre. Piles, culvert timber, ties and poles were obtained from native timber, but lumber was imported for bridge trusses and decks. Track-laying was done partly by steam tracklaying machines.

The heaviest construction on the entire line is along the north shore of Turnagain Arm. Occasionally there are short benches which were utilized for the roadbed, but for the greater part of the distance the roadbed had to be formed along steep slopes. The country is so rough that it was impossible to avoid heavy work even by the liberal introduction of curvature. In many cases heavy sidehill fills were made to avoid expensive cuts in the precipitous rock bluffs. The slopes of these fills extend into the water and are subject to erosion by the tides and waves. Timber culverts and trestles are numerous, with timber truss bridges over larger streams. It is estimated that about 8000 ft. of snowsheds will be required in this district. These will have to be of substantial construction in order to resist the slides, which start from long distances up the cleared mountain side.

How Materials Were Distributed

For work north of Anchorage the camps were supplied largely by barges working along the east shore of Knik Arm. In order to expedite work on the Matanuska branch, materials were distributed for about 18 miles from the junction during a severe winter by bobsleds working on the bottom lands of Knik Arm and on the ice of the Matanuska River. Where the main line lies along the Susitna River for about 75 miles, materials and supplies were distributed along the first 50 miles by a stern-wheel river steamer of 100 tons cargo capacity, which had been used previously for construction work on the Grand Trunk Pacific Ry. On the next 25 miles the river is cut up into numerous channels, with intervening bars, so that navigation is difficult. For this part of the river three propeller boats of the tunnel type were used, having a draft of 12 in. when light and about 20 in. with a cargo of 30 tons.

In 1917 the Matanuska branch was completed, and in 1918 the tracklaying on the main line was pushed north to Talkeetna, the 16-mile link along Turnagain Arm also being completed. About 50 miles of track has been laid south from the Tanana River, and some work has been done around the northern terminal at Fairbanks, where the old lines of the Tanana Valley Ry. form branches to Chatanika and Chena.

William C. Edes is chairman and chief engineer of the Alaskan Engineering Commission. William Gerig is consulting engineer; F. D. Browne and R. J. Weir are engineers in charge; W. J. H. Fogelstrom is bridge engineer; F. A. Bailey and H. F. Dose are district engineers. The main offices are at Anchorage, Alaska.

Departures in Canal Design and Location Effect Saving

Minimum Excavation, Greater Bottom Width and Omission of Upper Levee—Full Tunnel Bore Used

By Everett N. Bryan
Chief Engineer, Waterford Irrigation District, Waterford, Cal.

DEPARTURES from customary practice in canal design and location have saved money for the Waterford Irrigation District, California. These departures have included changes in canal section, omission of the upper levee or bank, and grade changes in both canals and tunnels for the sake of economy. Canals have been satisfactorily located without using a transit. Mass diagrams have been used on excavation and embankment studies.

In one case the design of a canal of 100 sec.-ft. capacity which it had been proposed to construct with an 8-ft. bottom width, 1½ to 1 inner slopes and a 5-ft. water depth, had its bottom width increased 10 ft., its inner slope on the upper side changed to ¾ to 1, and the levee on the upper side entirely omitted. The prime reason for the change was that it was impractical to attempt to balance excavation and embankment quantities, because the materials to be excavated were largely talc, hardpan and soft sandstone, and wholly unfit for forming impervious levees. It was desirable instead to seek a design which would require the least depth of water above the natural ground surface with a minimum of excavation. The minimum depth of cut for the lower slope was fixed at 3½ ft. (except in the rare instances where the application of this minimum to the crossing of small washes would have introduced sharp and adverse curvature), and this minimum of 3½ ft. was increased to 4 ft. where outcroppings of hard material gave evidence of an unusually shallow earth covering and shortage of levee-forming material. Thus, in general, the maximum water depth above the natural ground surface was 18 in. and this was decreased to 12 in. or less when there was an exceptionally small amount of soil.

Greater Freedom for Scraper Movement

The advantages of the adopted design were found in greater freedom of movement for scraper teams in the bottom of the canal and a very considerable reduction in the quantity of excavation. An 8-ft. bottom width is a little narrow for easy operation of a four-horse scraper team in so deep a ditch in other than "cross-fire" work, and the alteration of the shape of the cross-section effected a reduction in the volume of excavation required, ranging from 6% for a 3½-ft. lower-slope cut on a ground-surface slope of 1 on 6, to 24% for a 4-ft. lower-slope cut on a ground-surface slope of 1 on 3½. The ground-surface slope for this particular canal varied between these limits on the sidehill location.

The omission of the levee on the upper side gave a considerable increase of materials for the levee on the lower side, where it was particularly important to strengthen that bank. There were few instances where the omission of the upper bank permitted the canal to spread out over more than a few feet. In addition,

the absence of an upper levee simplified to a great extent the problem of caring for drainage from above the canal. Had an upper levee been constructed, the number of passages through it or of culverts beneath the canal would have been very great and would have required a large expenditure. Without it, the drainage is collected by the canal and discharged at comparatively infrequent intervals through waste gates in the lower levee, where a minimum of damage will result.

Saving by Single Levee and Change of Location

The application of this plan of using a single levee was not abandoned in one extreme case where the water in the canal spread out to form a lake reaching back about 800 ft. and flooding several acres. At this point the original location followed the usual practice of a 3½ ft. minimum cut for the lower slope, and only a very small area was flooded. The location was changed when it was revealed by a new survey that by throwing a levee across the cañon at a lower point the length of the canal could be shortened 1700 ft., with attendant saving in grade and a 36% saving in construction cost over that of the original location, after paying for flooded ground and a levee of double strength.

The not uncommon practice of diminishing the section and increasing the grade was sometimes adopted for portions of canals lying in deep cut, but accomplishing much economy in this way requires a considerable sacrifice of grade, and this was not always practicable. In such cases another alternative was adopted—that of dropping the bottom grade and narrowing the section. This effected a considerable saving in excavation, with no loss in the water cross-section, and with the use of short, taper sections return could be made to the old grade at the lower end of the cut, without appreciable loss of head. A canal 4 ft. deep with an 18-ft. bottom width and ½ to 1 slopes may thus be narrowed to one of 13½-ft. bottom width and the same slopes, by dropping the grade only 1 ft. and creating a water depth of 5 ft. The water area will not be decreased, and the economy effected will vary from nothing for a 4-ft. level cutting to 10% for a level cutting of 20 ft. Still greater economy may be effected by a further lowering of the bottom grade.

The "jumping up" presents some difficulties to the lay mind, but it may be understood that it presents no real obstacles if one will but pause to study the bottom grade of any of nature's water courses. He will find there a grade which is not always continuous, but often adverse. Where the banks are obdurate, nature has a way of digging down for more room, and when again they offer less resistance than the bottom the grade of the bottom is "jumped up."

Saving Effected by Using Full Tunnel Bore

This method of economizing in the deeper sections of canal excavation is particularly applicable in the design and location of tunnel sections. Tunnels are often seen on irrigation, municipal and hydro-electric developments with the bottom grade located continuous with that of the canal above and below, and an area above the water surface almost equal to, if not greater than, the water area. In many of these cases it would have been practicable to lower the bottom grade so as to use the full area of the bore and thus save largely in the cost.

In one case, on a Waterford Irrigation District canal with a water depth of 5 ft., the bottom grade of the tunnel was dropped 3 ft. so as to fill the entire bore. The grade was not again "jumped up" until the lower end of the lower approach cut was reached. This was about 1300 ft. from the portal. The canal bottom in this approach cut was 8 ft. wide and the water depth was 8 ft., with side slopes of ¼ to 1. To have secured the same water area with an unbroken continuity of grade would have required a canal bottom width of 14¾ ft. and ¼ to 1 slopes. The center cuts of this approach ranged from 28 to 8 ft. To have constructed this canal with an unbroken grade would have increased by 23%, excavation for the average cut in this portal.

Wasteway Provided to Cleanse Pocket

To cleanse the pocket created by the dropping thus of the bottom grade in the tunnel and lower approach, a wasteway was provided at the lower end. This continued the low grade to an open spill. Materials sloughed from the sides of the canal or tunnel may thus be sluiced out by occasionally diverting the discharge of the canal through the wasteway.

That the pockets so formed will fill to any great extent is unlikely. Débris or silt carried in suspension in a canal will not deposit unless the velocity of the stream is arrested, and this does not occur in such a case. Particles being rolled along the bottom may find difficulty in negotiating the grade at the point where the "jump up" is made, but in most cases this will cause little trouble. The increased water depth on the canal sides and the saturation of the top of the tunnel may induce a tendency to slough. Both this and the likelihood that pockets will fill must always be considered.

Where the materials taken from the canal prism were suitable for forming levees, an effort was made, of course, to balance the cut section with the fill section. On the side-hill location with a single levee it was found that the lower-slope cut would vary only a very little in securing this balance. It increased slightly as the inclination of the slope of the natural ground increased. The proper depth of cut at the lower slope could be easily determined for the various ground-surface slopes likely to be encountered, and because this depth of cut changed so little it was easy at any time to locate it on the hill side and know that a reasonably close balance of excavation and embankment areas was secured. The center cuts for the various inclinations of the ground surface were also computed, and it was these which were actually most used in the location work. They changed rapidly as the inclination of the ground surface changed, but with a little practice rodmen soon acquired the knack of calling for the proper cut. It was but a moment's work at any time to correct or verify the rodman's judgment by stopping to catch the lower slope.

Transit Not Used on Location

A transit was not used in location, and the work proceeded somewhat as follows: Without particular attention to alignment or chaining, the rodman proceeded from station to station, setting temporarily the

center stakes at an elevation on the side hill which would as nearly as practicable give proper balancing quantities—the levelman assisting by placing him where the cut would be that called for by the rodman. When in doubt, the rodman stopped to test his judgment by finding the cut at the lower slope. When the limit of the range of vision for the level "set-up" was reached, the rodman returned over the line to the initial point, ironing out the abrupt changes in the alignment. Beginning there again, he worked forward over the line, carefully chaining in and establishing the center line and taking cross-sections—the tapeman lining him in always to the next temporary center peg ahead. When the limit of the levelman's range of vision was again reached he moved forward. If a line of check levels be excepted, only once was it necessary to run an instrument over the line.

Now that construction of these canals is complete, it is doubtful that any difference could be detected between these canals and those located with the aid of a transit, unless the former should attract attention by reason of the evenness of their construction, because of the perfect balance between excavation and embankment. Nature has a marked tendency to work in easy curves, and as has been aptly said by an eminent engineer of the older school, "Water is not very particular just how it goes, so long as it can keep sliding down hill."

Mass Diagram for Each Canal

A mass diagram was worked out for each canal as soon as the yardage could be computed. It was the aim always to have this curve climb a little, and thus show an excess of excavation, to provide for the shrinkage which will almost inevitably occur in moving earth from excavation to embankment. If the curve was found to vary unnecessarily, the matter was considered by the chief, together with the locator. An estimate of the cost of relocation was easily made, and this was compared with the possible yardage to be saved thereby. A 100% perfect relocation would effect a 50% reduction in the excess cut or borrow, but in practice it is impossible of course to secure such a relocation, even were it desirable, and it is needless to say that in many cases the 100% perfect relocation, so far as lack of excess cut or borrow is concerned, is not the best location.

The locators soon developed a keen desire to develop the best mass curves practicable, because these were "yardsticks" by which their skill was readily measured. A miscalculation on the original location was an interesting field for speculation as to the percentage of perfection which could be obtained by another try. If it were known that the cost of a relocation, with attendant office expense, would be more than compensated for by a reduction in the cost of excavation, the relocation was made, regardless of the layman's censure of another survey or the additional charge to engineering expense.

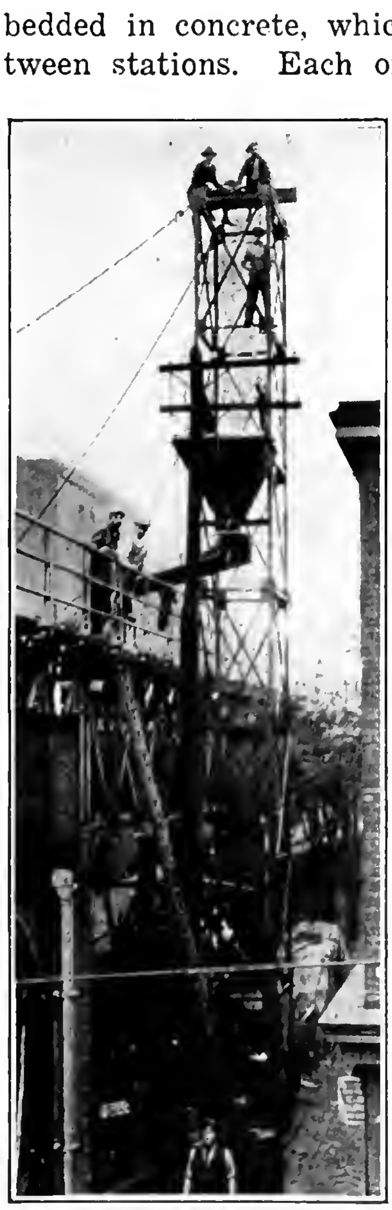
The mass diagrams were placed at the disposal of contractors bidding upon the work and were interpreted to them if necessary. In the preparation of monthly and final estimates they were found invaluable. Duplicates were furnished to the foremen in charge of the grading crews. At first they had some difficulty in getting away from the idea that these were some sort of modified profile, but they generally did get away from such idea, and it was not long before many were ardent students of their mass curves and were cutting their haul effort to a minimum.

These were but a few of the economies practiced in the matter of the canal location and design. With such savings, together with those practiced in other branches of the construction program, success was achieved in putting through, without diminution in quantity or quality, during the years 1916, 1917 and 1918, the work intended to be done by bonds voted early in the first-named year. This was accomplished in spite of the phenomenal rise in prices which began late in 1916 and raised the cost of most construction by from 10 to 60% of the original estimate on which the bonds were voted.

Movable Towers Concrete Deck of Philadelphia Elevated

Station Work and Straight Sections on Six-Mile Stretch of Frankford Line Divided Between Two Mixing Gangs

HAVING one crew organized and trained for the straightaway concreting work between stations, and another with a separate organization for putting in the different type of deck required at stations, is the method adopted by the contractor in concreting the deck of the Frankford elevated line in Philadelphia. The stations have a track section with short ties embedded in concrete, which ballasted track is used between stations. Each of these gangs uses a mixing plant on the street, with a 40-ft. steel tower to hoist the concrete to runways on top of the structure. Each gang has two towers and two hoists, so that one can be moved and rigged while the other is being used.



PORTABLE TOWER PLANT

The Frankford elevated line, part of Philadelphia's new rapid transit system, was well under way when the war broke out, and now is so nearly completed that it is hoped it can be put in operation at an early date. The steelwork has been erected from Callowhill St. in Philadelphia to Deyer St. in Frankford, and about half of the 27,700 yd. of concrete to go in the track deck over this six-mile stretch has been placed. The steelwork consists of two types. One has columns on the sidewalks, capped by transverse plate girders which support three lines of longitudinal lattice truss girders, one between

the tracks and two outside. In the other type the three rows of lattice girders are carried on a line of single column bents between the car tracks in the center of the street. The problem of concreting the deck is the same on both types, the deck consisting of jack arches between cross beams at right angles to the track carried by the longitudinal lattice girders. As may be seen from the photographs, the concrete deck does not extend quite to the center of the outside girders, being carried only 12 ft. out on each side from the middle girder.

Sheet steel forms, curved to fit the arch section, and flanged along the bottom edges to rest on the lower flanges of the I-floor-beams were used. Each form section is 3 ft. wide and is collapsed by two turnbuckles. There are thus four of these forms to one arch on each side of the central girder, and with an average progress of 100 cu.yd. or a little more than 100 lin.ft. of structure per day for each gang, enough forms for about 1000 lin.ft. of double-track structure were provided. When the placing is being done close to the tower, and the buggy run is therefore short, as much as 160 lin.ft. is accomplished in a day by one gang.

Work on the deck was begun at the end of October, 1917, with a traveling mixing plant mounted on top of the structure. This plant, before it was closed down for the winter, concreted about ½ mile on Front St., where the base of the rail is 45 ft. or more above the street level on account of several railroad crossings. The plant consisted of a ½-yd. mixer supplied by overhead bins holding material for about 8 yd. of concrete. On the rear end of the traveler was mounted a small derrick, which supplied the bins, using a dump bucket. Three buckets were used, being loaded by hand on the street with sand and gravel. The derrick also hoisted the cement. The entire rig was mounted on one set of timber stringers and rolled on another. It occupied only the east half of the elevated structure, and, on account of the design of the steelwork, it was difficult to move it. The central girder of the steelwork was

TRAVELING PLANT SUPPLIED BY DERRICK

at the same elevation as the outside girders, but sidewalk brackets carried on top of the outside girders prevented rolling the traveler on it. It was therefore necessary to use a platform of 12 x 12-in. timbers, extending from the center girder to the outside girder and resting on the latter between the sidewalk brackets to carry the stringers on which the traveler was rolled. These timbers were taken out and swung ahead by the derrick, which was placed so as to reach both ends of the traveler. It is stated that this plant proved to be slow, for its output was limited by the capacity of the one derrick.

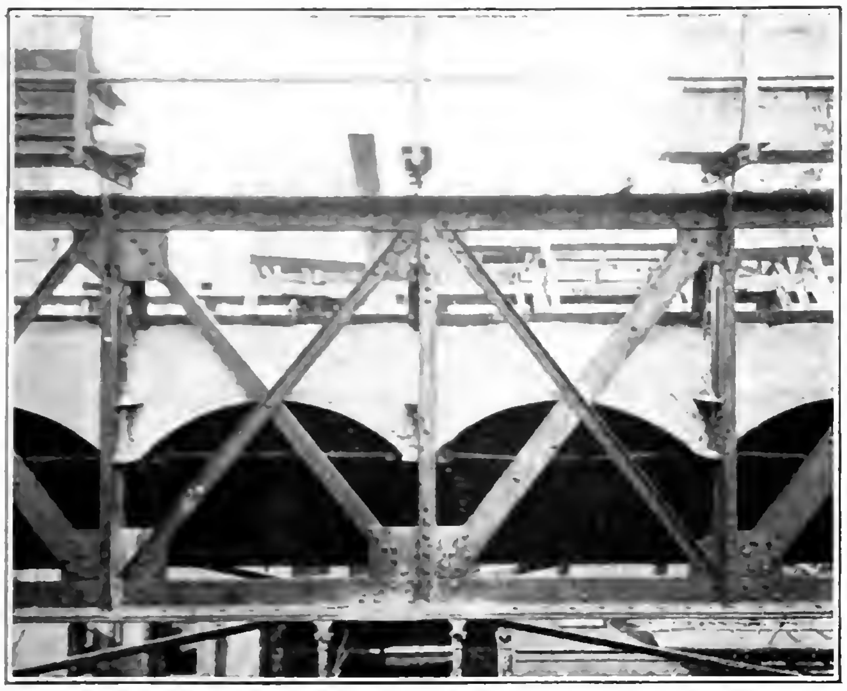
When work was resumed last spring this traveler was dismantled and four steel towers were placed on the job. These were set up at street intersections and a length of one block each way was concreted from each set-up. While the concrete gang is using one plant, the rigging gang takes down the last tower and hoist and moves them ahead to the next set up. The towers are erected in sections, with a gin pole and crab. The plant investment is reduced by using only two ¾-yd. mixers.

These are mounted on wheels and are pulled along the street by a truck. It is possible to move one of them and set it up while the gang is moving and reassembling the runways, buggies and forms. The mixers are of the type that is loaded by a charging hopper filled with wheelbarrows from material piles on the street. Sand, gravel, and cement are delivered in motor trucks by the material-supply firms, to the mixers.

The main runway is carried on the central lattice girder, the buggies being dumped down a movable chute into the section being poured. This runway is connected by a plank bridge about 12 ft. wide to the side of the structure at the tower, giving the buggies room to come up and turn under the hopper into which

CONCRETE PLACED BY BUGGIES FROM CENTRAL RUNWAY

the tower skip discharges. As the work progresses away from the tower, passing platforms long enough to hold about two buggies are put in at the side of



FORM COLLAPSED BY TURNBUCKLES

the main runway, being carried on joists to one of the outer girders.

The deck is divided into sections by the steel plate transverse girders which support the longitudinal girders, the spans varying from 42 ft. to 72 ft. It is usual to pour from two to three of these sections in a day, averaging about 100 yd. of concrete for each gang. The largest runs have been about 160 yd. The concrete gangs employ each from 38 to 40 laborers, four carpenters, three or four cement finishers, two to three foremen and two engineers. Each gang is under its own superintendent. While of about the same size, the gangs are organized differently.

The deck between stations is finished with a smooth top, on which a ballasted track is to be laid. The deck at stations is carried up to within 3 in. of the bottom of the ties, and paving stones are half embedded under each rail in the space between the ties, to form a bond between the deck and the concrete in which the ties will be set. When the station gang has finished all of these sections it will go to work on the curve sections, where the floor-beams spacing is irregular and special forms are required.

The erection of the steelwork was completed in 1917. The construction of the track floor, walk ways, and drainage provision was let to the Keystone State Construction Co., which sublet the concrete track floor to the Union Paving Co. The work is being carried on under the Department of City Transit of Philadelphia, of which W. F. Twining is director, and Henry H. Quimby is chief engineer. Construction is under the immediate supervision of M. Golder, division engineer.

New Law for Venezuela Railroad Concessions

A NEW law, states a commerce report, has been passed relating to railway concessions in Venezuela. New or changed provisions are as follows:

The Government will guarantee no interest on capital invested in the construction of railways.

A contractor for any railway must make a cash deposit proportionate to the length of the line and the width of gage—ranging from 600 bolivares per kilometer for 0.610-meter gage to 1400 bolivares per kilometer for 1.435-meter gage. The Federal executive may reduce this deposit at his discretion by as much as 15 per cent.

The Federal executive may or may not reserve in contracts the right of buying the railway and its equipment, with six months' notice to the enterprise. It is optional to the Government to make this purchase upon appraisal, paying 20% premium on the value of the enterprise, or by paying the price represented by value of the capital stock at the time of purchase with a premium of 10%. In all cases of purchase the appraisal shall be made by experts, and the purchase price shall be paid to the enterprise upon transfer of property.

The Federal executive shall have the power to require a reduction of rates when the annual tonnage transported by the road shall exceed a certain amount to be fixed in each case.

In contracts for building railway lines the following franchise shall be granted: Free duty on importation, during the first 25 years of the concession, of rolling stock, engines, tools, utensils and necessary implements for the building, exploitation and maintenance of the line and its branches, it being understood that said franchise shall lapse if it be proved that any of the exonerated goods have been designed to uses other than those of the company which obtained the contract, without express permission from the minister of public works. For the purposes of the exoneration of the custom duties the corresponding provisions of the code of finance must be complied with.

California Water Commission Advises Change

Abolition of the salaries of two of the three members of the California State Water Commission, making the remaining salaried commissioner the sole executive officer in water-right appropriation matters, with right of appeal to the full commission, is recommended in the second financial report of the commission. The recommendation is based on a study of water-control methods in 15 "irrigation" states, which study shows that in nearly all cases the plan recommended is in force. A vital need exists, the report states, for legislation giving an individual the right of eminent domain for rights-of-way for ditches, the same as is enjoyed by public utilities. This is necessary because it is required of anyone desiring to appropriate water that he have the right of access to the proposed point of diversion, and because of the frequency with which such rights have been withheld when an offer of reasonable compensation has been made. The commission began operations in December, 1914, and up to Sept. 1, 1918, had considered 1059 applications for water for agricultural, mining, power and domestic purposes. The commissioners are A. E. Chandler, Berkeley, president; W. A. Johnstone, San Dimas, and Irving Martin, Stockton.

Training 350.000 Men for the Shipyards: How the Fleet Corporation Met the Problem

By J. Will Parry

Lately Executive Assistant to the Director of Education and Training, United States Shipping Board, Emergency Fleet Corporation, Philadelphia

Building ships for the war emergency required many men, an army of skilled workers, to be assembled and trained in the shortest possible time. Ordinary methods of training were hopelessly inadequate for creating this force. The Emergency Fleet Corporation developed new methods by which it solved the problem. Personal training by working instructors made from intelligent yard mechanics is the core of the solution. Schooling for foremen and executives, to improve leadership, constitutes an important auxiliary development. Numerous other special fields of training called for the Emergency Fleet Corporation's labors. Mr. Parry, who was in close contact with the direction of the Education and Training Section of the corporation until his departure for Europe to take up educational work in the Army, sketches very briefly the methods used and some of the results attained.—Editor.

Early in the emergency shipbuilding the man-power problem was seen to be one of almost startling magnitude. There were about 40,000 shipyard workers in the country—not all of them in the shipyards. The full complement required to produce the ship output projected was about 400,000. Thus—disregarding that bothersome leak in the bottom of the pail, labor turnover—every shipbuilder had to be multiplied by 10, and that, too, at a time when all industries were bidding for skilled men.

Dilution processes, which depend on the survival of the fittest, could develop these men. But these are slow processes, and the men for the shipyards had to be developed rapidly. Furthermore, dilution would have involved, inevitably, a material loss in production, due to the skilled workers having to give time to instruction. Clearly, the task was hopelessly beyond the reach of dilution methods.

Three Sources of Labor

Labor could be obtained from three sources: First, skilled shipyard craftsmen not already employed could be impressed into the service (the supply from this source would be so soon exhausted as to make it a negligible factor in the problem); second, mechanics not trained in shipbuilding but skilled in crafts similar to the shipyard trades could be "converted" to the particular operations required in the shipyard. With men obtained in such ways might be considered partially trained mechanics in shipyards who could be developed to higher degrees of skill. Together, these groups could furnish a supply somewhat larger, but still hopelessly below the needs of the case. As the third and only remaining source, there was the supply of unskilled labor—green men with little or no knowledge of any mechanical trades. In view of the numbers required, this was the only source offering hope of meeting the needs of the case.

Thus, the kernel of the problem was, how to train absolutely green men and make them into shipyard workers, and do this rapidly enough to perform the work allotted to the yards.

Training men for shipyard occupations is not essentially different from industrial training of any other kind; and providing the men needed for quantity production of ships is essentially the same under emergency conditions of war time as under normal peace conditions. However, there was the magic bidding, "Do it quickly," and this, as a governing condition, did effectively stimulate decision, sweep away suspicion, and bring out into relief and place in proper grouping many facts and tendencies of training which under normal conditions of development come to light so slowly and in such scattered form that they are not easily distinguishable.

Nature of the Essential Training Task

When the shipbuilding program was planned, the shipyards of the country were forced to think in figures entirely beyond the customary in magnitude. Few of the managers could perceive all their problems clearly enough to be able to set them down in proper order and attack them consecutively. In consequence, plant construction got ahead of housing conditions, steel supply was now ahead of hull construction and now behind, and, in general, things moved by jerks rather than smoothly, as is inevitable with any great, unestimated project that is still finding itself. The man-power problem was one of the earliest and most obvious in claiming attention, and it remained the primary problem throughout the whole stage of shipyard development hardly concluded yet. The 61 shipyards, with 235 ways, of the early part of 1917, had grown to 198 yards, with 1083 ways, at the time the armistice was signed, and 80% of the ways were completed. This growth, and the numbers of men involved in both construction and in shipbuilding, will serve to define the problem of man-power, and hence that of training men.

The chief training problem was centered in the yards building steel ships. The seven concrete shipyards among the 198, for example, use, largely, unskilled labor. Wood shipbuilding, carried on in 114 yards, presents a much simpler labor development problem than steel shipbuilding. There is not so great a diversity of trades to deal with, and related trades of ready conversion possibilities are more numerous; also, dilution can be more readily accomplished, as the typical gang organization of the work is more nearly the

proper organization for training green men The 77 steel yards, therefore, presented the main bulk of the training problem. Again, in these, the hull construction trades constituted the most immediate need.

Ten trades called for trained workers in the largest numbers. These were: Bolters-up, chippers and calkers, drillers and reamers, erectors, rivet heaters, holders-on, riveters, shipfitters, ship carpenters, and electric welders.

Emergency Training Method Applied to the Main Problem

Two fundamental premises underlie the emergency plan of training developed by the Education and Training Section of the Emergency Fleet Corporation:

1. Learners must be instructed by work on production jobs, because: (a) Counterfeit jobs do not present a sufficient breadth of field for all-round effective training; (b) keeping learners off production work means waste of material and tools; (c) the stimulus of working on a job which will go to sea rather than on a play box is essential—as was recognized very early in the work.

2. Instructors handling gangs of learners must be men who are expert in the trade in which they are instructing, and who at the same time know how to teach it, and are free to produce skill rather than riveted plates. Training is essentially a production job, but its main product is skill, its byproduct is finished goods.

Production work, and working teachers, were thus the two essentials.

Any experienced training man will recognize at once that the critical element in this enterprise was the corps of instructors, the "skilled mechanics, who can teach." Teaching ability is sometimes called a gift. Emergency does not wait for gifts, however. It was necessary to develop the required number of yard instructors by training. The Emergency Fleet Corporation's training question, then, was to train yard instructors for training green men in yard crafts. The scheme developed for this work was to put selected mechanics through a training course designed to give them the necessary teaching ability. The success of the plan may be briefly indicated by saying that on Nov. 10 there were on the job 1100 yard instructors who measured up to their work about as well as do college professors or public-school teachers; and the training capacity of America's shipyards was somewhere around 15,000 men a month.

Mechanism of the Instructor Course—the Four Blocks

The mechanism of the instructor-training plan of the Emergency Fleet Corporation (shown by the diagram on the following page) is essentially this:

Selected mechanics of proved ability from various shipyards are sent to an instructor-training center for a six weeks' course. The class is under an instructor who knows teaching methods. His main function is to assist each man to classify his knowledge in such manner that he may be able to impart it effectively to others. The instructional material of the course is arranged according to a scheme developed by Charles R. Allen, superintendent of instructor training. Its characteristic is a division into four blocks, as will appear from the following outline.

Block 1—Job Analysis—Includes the analysis and arrangement of the occupational knowledge in an effective instructional order of jobs. The prospective instructor's knowledge of his trade is taken in the form and with the peculiarities as found; no attempt is made to impart trade knowledge or to teach standard practice.

Block 2—How to "Put It Over"—Telling what instruction is and how to accomplish it. The learner is made familiar with the successive steps in the instructing process, methods of approach and the like.

Block 3—Establishing an Effective Instructional Order—Teaching how to lay out operations in a difficult scale and establish checking levels for determining the progress of the learner.

Block 4—Instructional Management—Importance of good management for the emergency program; gang organization; meeting instructional conditions; getting along with production departments, and maintaining relationships.

Results of the Training Work Briefly Stated

Organized as suggested in the preceding, the training of instructors grew to remarkable proportions. The growth of training centers and of yard training departments has kept pace with the development of the shipyards and with their advance from the stage of plant construction to that of production.

On Apr. 15, 1918, three instructor-training centers were running; on Nov. 10 there were 36 centers. Thirty-eight shipyards had installed regular training departments, and 19 others had modifications of training departments. Training was proceeding in 42 trades and occupations.

The training capacity, based on the number of trained instructors, was not far from 15,000 men a month. Two yards were equipped to train 2000 green men per month each. Ten yards could train more than 500 green men a month.

What kind of instructors were being produced? The yard instructors went out from the training centers with the zeal of crusaders. They not only saw their trade or job in a new light, but they were fired with the consciousness of the power "to put it over"; and, not the least valuable characteristic, they had an entirely different—an almost impersonal—viewpoint as to the value and possibilities of the green man.

There had been an "instructor turnover." Instructors were lost through the yard gobbling them up for production foremen, for example. Training work has suffered from labor troubles, housing conditions, material supply slip-ups, and countless other difficulties. But so far no criticism has been made that the yard instructors could not "produce the goods."

An Experience: The Instructor's Faith—To a new yard instructor in a Great Lakes yard was assigned the job, as part of his practice teaching—before he got out from under the eye of the staff man—of instructing a green hand in laying off some angle clips. These had to be punch-marked and lettered with a brush, to conform to the mold. An especially green man had

NAME.................................. .TRADE .... .INSTRUCTOR........................

been picked for this teaching practice. The learner completed the operations, but it was seen that he labored very hard over the lettering. On investigation it was found that he could neither read nor write.

Here was a difficulty which the old-time "breaker-in" would have given up in despair; not so the new instructor. Referring to the learner, he said, "But he's all right. He can *learn*. He showed it by the way he laid off the piece."

Instructor-Taught Men Efficient—In a certain North Atlantic yard the management was in a tight place with respect to riveting on a hull that was behind schedule. Ten riveting gangs still under instruction were pulled off the school work and put on the hull, along with 17 regular production gangs. The two sets of men worked side by side on the hull; there was no coddling or favored-job arrangement about it. The day's average for the new gangs was 278 rivets, that for the seasoned gangs 138. The highest drive of one of the new gangs was 318. The highest drive of one of the old-timer gangs was 240.

What the Professor Concluded—A former college professor who had deserted the field of economics to learn shipfitting passed through the "system," and, aided by native ability, advanced rapidly enough to become inspector on hulls. "I have never encountered a piece of teaching," said this specialist in instruction, "which took a fellow from where he was to where he was going by such direct and effective steps."

Improving Leadership the Second Great Problem

An army, no matter how efficient and well disciplined its troops, cannot be effective if it is not handled by capable officers. So, with the tremendous expansion of the shipyard working forces, the need developed automatically for more and better foremen, superintendents, quartermen, leaders and higher executives. This need was supplied in the time-honored way of picking a good mechanic, or a man with promise of leadership, and making him foreman. The results were as good as those in any industry using the same method of selection and bidding the new foreman "go to it"—and they were *no better*.

The foreman, using the term in its now common industrial application, makes or breaks the organization. Yet he is ordinarily left to his own salvation, to work out his own problems and plan his work. It was soon recognized that improvement in this part of shipyard operation was vitally necessary. The Emergency Fleet Corporation, therefore, organized classes in shop management and modern production methods.

These classes did *not* train men to become foremen; they trained foremen and executives already in the yard, to make them better foremen and better executives. No ready-made scheme or preconceived system could serve in this work. Each yard and its personnel were looked upon as a special problem, requiring its own individual treatment and solution, though of course the underlying principles of good management found application in each instance. As in the case of training the yard instructors, results were secured chiefly by guiding the individual through some of his own problems, and thereby imparting to him the ability to separate, analyze, lay out and schedule his own work in effective fashion.

Two very important and valuable byproducts developed: (1) A team spirit among the men, and a feeling that all were pulling together; (2) the successful solution in conference, sometimes in blood and tears but more commonly with gain of mutual respect, of certain "tough-nut" problems that had been in everybody's way.

Thus, in a New Jersey shipyard a certain group of men, all in the hull-construction department, and all from the same ways, had developed a tender spot over the use of the cranes. The men were more than merely touchy on the subject; they were completely at logger-

heads; each man cherished the idea that the other fellow was waiting just around the corner to "do him dirt." By devoting several hours to the matter, with the aid of the instructor as referee, carefully analyzing the problem, it was worked out to everybody's satisfaction, with the relief of much tension.

On Nov. 10 fifty-four foremanship classes were running. They were attended by more than 1800 men. One yard enrolled over 700 of its minor executives. In at least one case the coöperative spirit generated in these classes produced a most obvious result: By the action of the spirit of power and heave-together resulting from the foremanship conferences, a certain hull that had long been behind schedule and was daily slipping farther behind went into the water on the contract date.

Schooling the Trained Shipyard Worker

Manual instruction on the job gave little opportunity to provide the mechanics with that part of their equipment which may be described as the technical knowledge related to the trade. This knowledge is of vital importance in stimulating ambition, developing short-enlistment men into skilled and permanent employees, and creating in the individual a pride in his occupation. To aid in providing this knowledge, the Education and Training Section developed the Supplementary Training Branch. The work was done mostly through classes organized on the familiar plan of evening and part-time schools.

Over 8000 men in 38 yards have enrolled in such courses. The seven fundamental courses prepared and published for the work are: Elements of blueprint reading, blueprint reading for steel-ship construction, blueprint reading for wood-ship construction, elements of wood-ship construction, course for shipfitters, course for marine pipefitters, course for machinery erectors.

It is beyond question that such supplementary instruction succeeds in developing and holding craftsmen in all lines of industry. An extreme example comes to mind of the results that may be secured. The director of training of a certain Great Lakes yard organized evening classes. Among others there reported a man nearing 50, who had for 20 years been a common laborer in the yard. Instructors were skeptical of the chances of a man so old, and apparently so deep in a rut, ever climbing out. Nevertheless, he received a trial in the school. Today the man is a second-class shipfitter, and is still climbing.

Special Problems Handled by Specialized Methods

In many lines of war work it was found necessary to take craftsmen from various trades and make them into craftsmen for the specific war work in hand. In the shipyard field this "conversion training" was handled as a branch of the intensive training work.

Essentially, the method of handling it comprised analyzing the man's previous trade experience and, using this so far as possible, building up the training necessary for the new occupation.

Notable examples of such conversion were making ship riveters from structural steel riveters, ship carpenters from house carpenters, marine pipefitters from plumbers and steamfitters, coppersmiths from sheet metal workers, and outside machinists and machinery erectors from machinists. Careful and expert supervision and follow-up were essential in this instruction, chiefly in order to make sure that the men were getting just the type of jobs which would rapidly "convert" them.

Electric welding came up as a new problem. Its application to steel-ship construction, stimulated by the war program, has already passed through the experimental stage, and today it should be said, perhaps, that electric-welded ships are rather more than a possibility for the future. Here the Emergency Fleet Corporation found it important to work not only on the development of the art, but also on the training of men in this entirely new craft. To the latter task the plan of intensive training was also applied. About 100 craftsmen have been trained, in consequence, and some 200 are now in training.

Naval Architects Needed—In September the shipyards of the country made a call for 200 to 300 men of technical training in naval architecture and marine engineering. To meet this call, eleven-week courses were developed in two prominent universities. Only men of engineering training were admitted to these courses. As they already had the preparatory knowledge, as much naval architecture and marine engineering could be given to these men as is ordinarily given in a regular four-year course. Further demand for technical men by the shipyards will undoubtedly be met by the necessary response from universities and technical colleges.

That shipbuilding will live as the result of its revival under the stress of emergency—that it will adapt itself to peace conditions and remain an essential part of American industrial life—must today be regarded as assured. The need for trained shipyard workers therefore will continue. The national emergency has also brought out specialization in higher degree than known before. The trend will be toward the development of trades largely new to the American people. Whatever the course of coming development may be, however, shipbuilding will have the advantage of a more ample fund of training experience than any other industry in the country. This training constitutes a secure foundation for the future.

Omaha Public Works To Cost $2,000,000

An extensive program planned by the Department of Public Improvements of Omaha, Neb., will involve the expenditure of about $2,000,000 for sewers, paving and grading, and the extension of the park and boulevard system. The paving projects include the improvement of the main arteries leading into the city and the principal connecting streets, which will cost approximately $500,000. For parkway and boulevard development there will be acquired about 160 acres of wooded ravines, sparsely covered with dilapidated dwellings. The sewer work includes the construction of a trunk line system outside the city limits, and a disposal plant to serve the Saddle Creek drainage area. The planning and execution of these improvements are under the direction of John A. Bruce, city engineer.

Fabricating Shop and Berth Equipment at Sun Shipyard

Assembly Bay of Shop Delivers Finished Material to Shipbuilding Cranes—Multiple Punches and Roller Tables—Reinforced-Concrete Berths Served by Bridge Cranes

A FABRICATING shop specially planned along original lines for systematic working and direct routing of hull steel to the berths forms the central feature of the Sun Shipbuilding Co.'s new plant at Chester, Penn. The yard was designed 2½ years ago for building large oil tankers and cargo steamers; since December, 1916, when it began operation, it has put into the water 12 hulls of 10,000 to 13,000 tons, two of them said to be the largest freight steamers ever built. Among the features that give character to the yard, besides the shop, are concrete pile-bent shipways, bridge cranes on high runways serving the berths, a fixed hammer-head crane serving the wet dock, an excellently equipped boiler shop of capacity exceeding the needs of the yard, and a large engine and machine shop nearby—the plant formerly owned by Robert Wetherill & Co., Incorporated.

The enlargement and rearrangement of the fabricating shop are now being carried out to improve the balance of its departments. It is believed that when this work is completed the shop will rank second to none in the country for completeness of equipment.

In order to carry the idea of direct routing through from the raw-steel storage to the berths, the shipbuilding end of the Sun yard is arranged as a compact group. There are five shipways, and the shop stands immediately at the head of the ways, with a space of only 150 ft. between its delivery side and the bow of a ship on the stocks. The crane runways over the berths are extended to the shop wall, and the cranes take their material directly from the doorways of the shop, where the bridge cranes in the building deposit it.

Separate Layout and Assembly Bays.—As originally planned, the shop consisted of three sections forming one continuous building. The main section in the middle, 225 x 300 ft., is the fabricating shop, with its shorter side facing the shipways. Across the incoming end of this portion is a layout bay 80 x 500 ft., with a mold loft over it. In similar position across the outgoing end is an assembly bay 80 x 600 ft., so that the entire shop has an H-shaped layout. Some of the specially interesting structural features of the framing of the building were described in *Engineering Record* of Oct. 21 and Dec. 16, 1916, pp. 498 and 734. The layout and assembly bays are served by two bridge cranes each,

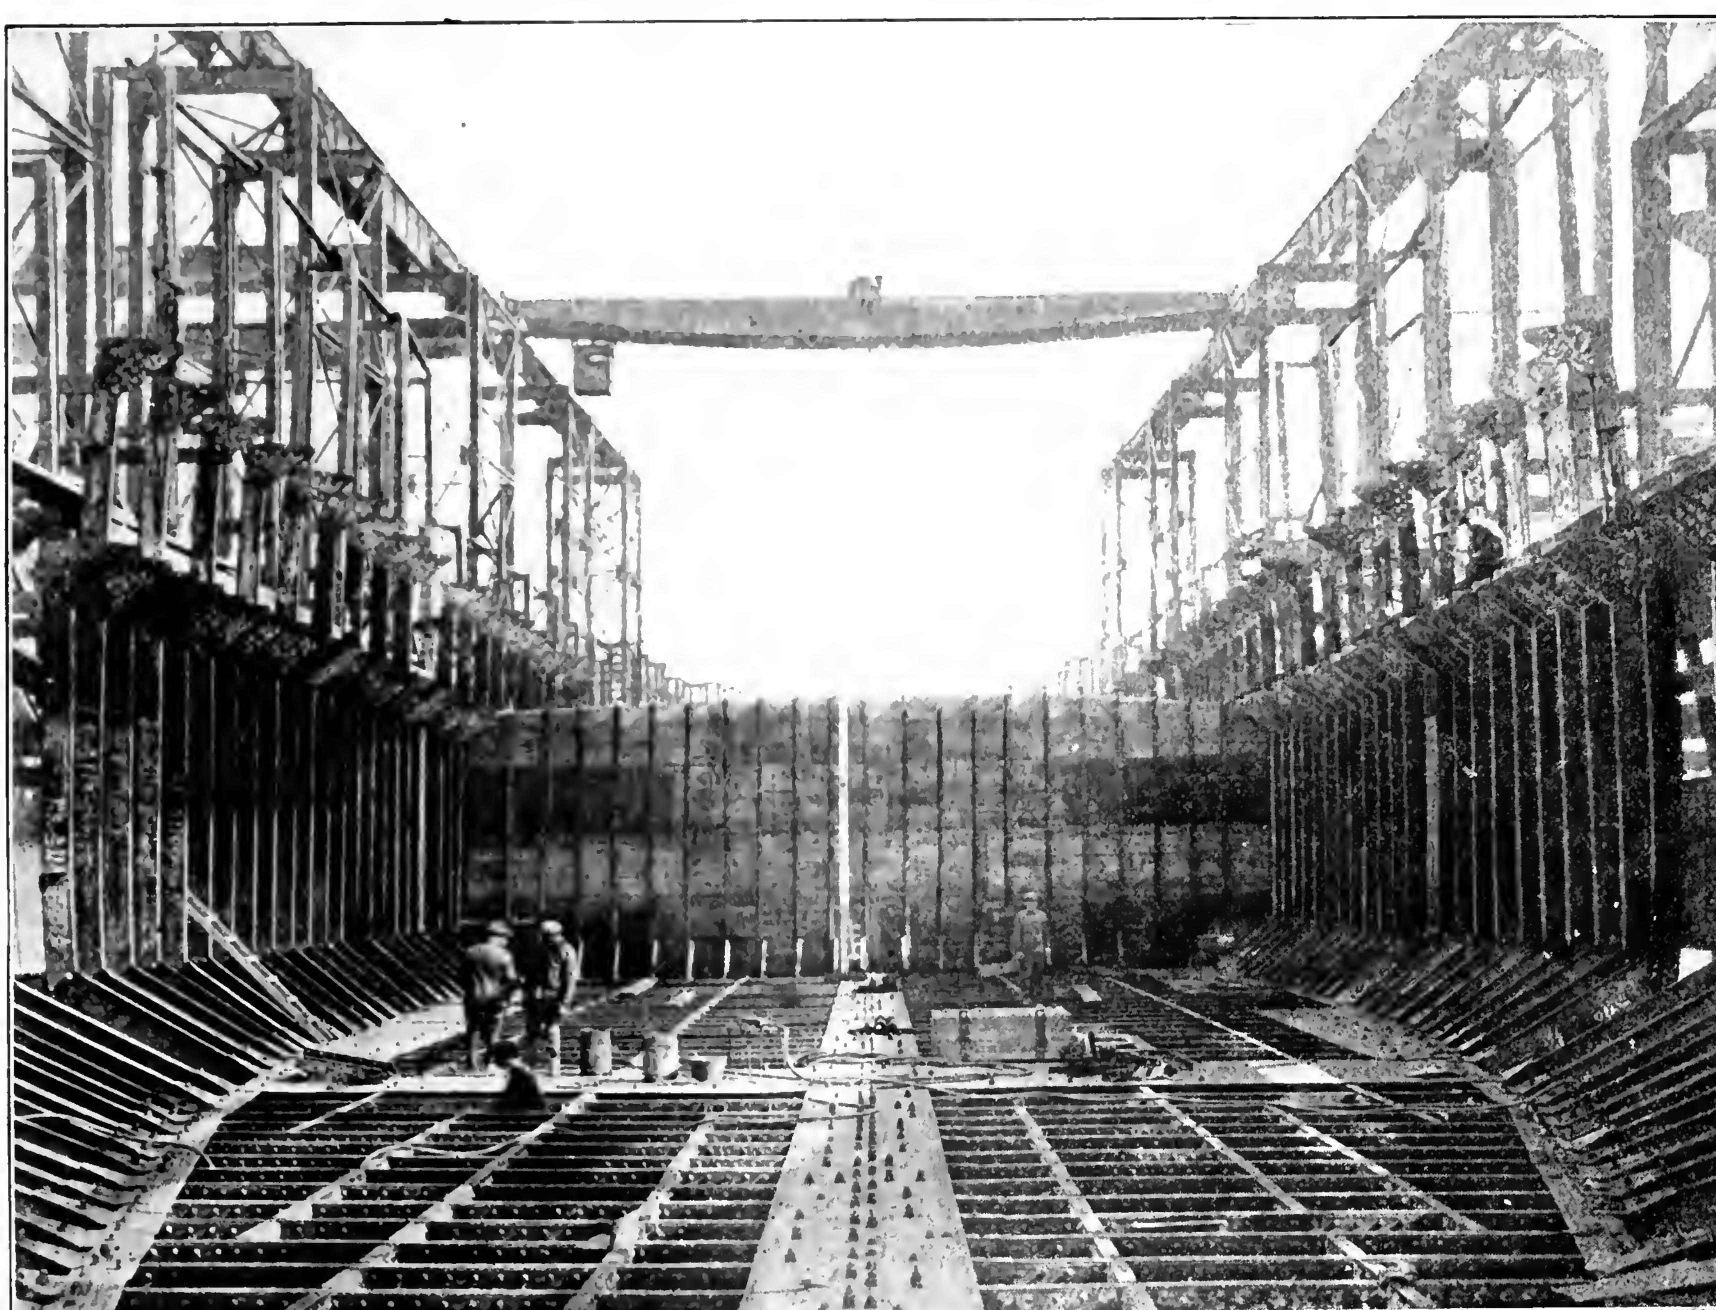

FIG. 1. AT SUN SHIPBUILDING COMPANY'S YARD CRANEWAYS 95 FEET HIGH COVER THE 80-FOOT WIDTH OF WAY; TWO CRANES ARE PROVIDED OVER EACH SHIPWAY

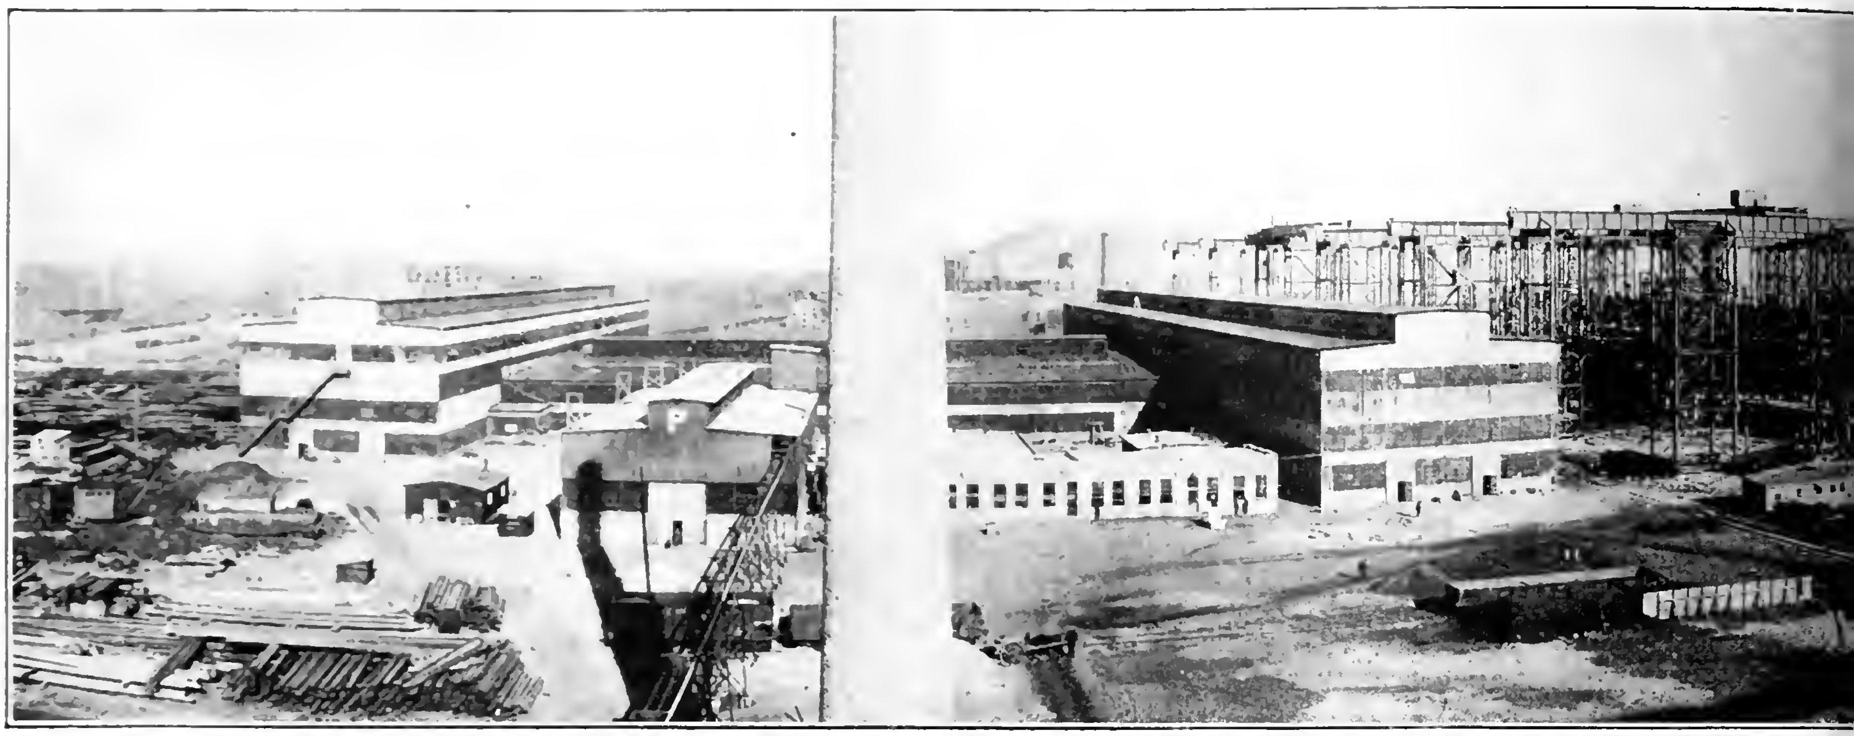

FIG. 2. LOOKING EAST TOWARD HULL CONSTRUCTION PART OF YARD SHOWS FABRICATING AND ASSEMBLY SHOP

spanning the full 80-ft. width of the bay and traveling its entire length. The fabricating portion of the building has no bridge cranes, but is equipped with a number of overhead I-beam trolley runways, and, in the plate side of the shop, extensively rollers beds for transferring plate.

Revision of the layout will consist in adding on the east side of the fabricating section a 115 x 300-ft. extension, making this section of the shop 340 x 300 ft.

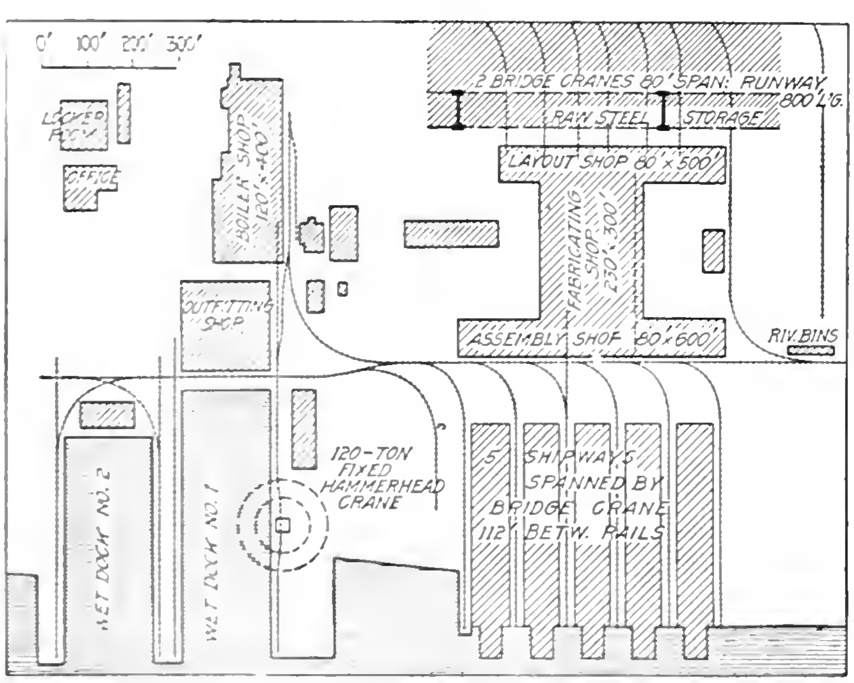

FIG. 3. GENERAL PLAN OF FIVE-WAY SHIPYARD FOR LARGE FREIGHT STEAMERS, SUN SHIPBUILDING

As indicated in the small sketch plans of the layout, Fig. 4, the addition will be devoted largely to furnaces and bending slabs, which will be moved from their present location separating the shape and plate fabrication. The shop as it now exists has ample plate capacity but inadequate shape capacity. The provision for straight shapes consists only of a single line of punches and shears along the east wall of the shop, with a longitudinal hoist trolley centered over the machines. Furthermore, the furnaces and slabs now separating the plate and shape sections not only interfered with any expansion of the shape-fabricating facilities, but also made it necessary to place a new plate multiple punch, acquired some time ago, in the layout shop. With the extension, and the furnaces and slabs accommodated there, the shape-fabricating section can be expanded as needed and room can be found within the area of the fabricating shop itself for the plate multiple and a new beam multiple.

The shop was designed for an ultimate capacity of 5000 tons of fabricated material a month. This would provide for a production of about 15 ships a year, counting 4000 to 4500 tons of steel per ship. It was thought, however, that a capacity of 150 tons per day per shift could be attained so that the day shift alone would be able to supply a production of 12 ships per year. It has not been possible to reach this output, but with the rearranged shop these figures should be realized.

Steady increase of the production of the shop has been recorded during the past season, through increasing efficiency of the working force. This is illustrated by the following figures for average daily output of the shop in four consecutive months, August to November: 180, 195, 222, 227 tons. All this is on two-shift work. The night shift has a materially lower output than the day shift, although the same number of men are at work and

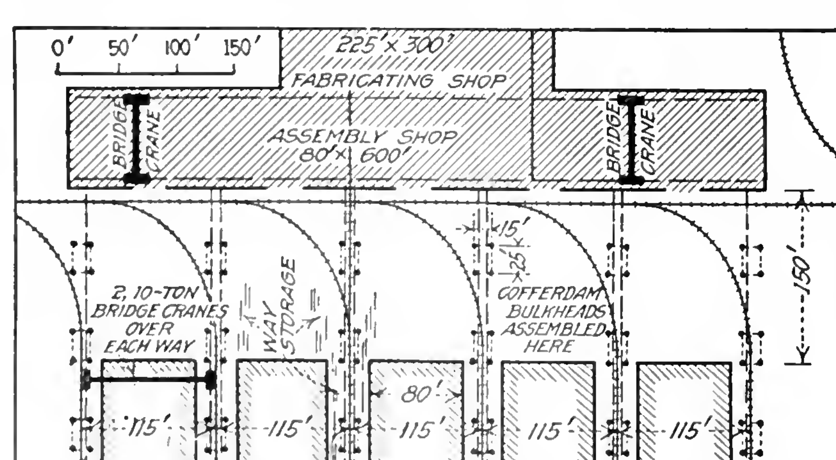

FIG. 4. SKETCH PLAN SHOWING RELATION OF FABRICATING SHOP AND BERTHS

Wet dock No. 2 is now under construction. Only the hull construction part of the yard is shown. An extensive machine shop and foundry plant belonging to the yard is located a quarter mile away

the working time is slightly longer. For November the total production of the day shift was 2866 tons and that of the night shift 1855 tons.

Handling Material Through the Shop—The roller-

(AT LEFT) AND SHIPBUILDING BERTHS WITH BRIDGE CRANES ON HIGH TRESTLES (IN CENTER) CLOSELY COÖRDINATED

bed equipment of the plate section of the shop can be seen in the view, Fig. 6. Originally these rollers served also for supporting and moving the plates at the punches, but during the past year ten Lysholm manually-operated punch tables have been installed, and the shop will be equipped with them throughout. A wide multiple punch is already in service, as indicated in the sketch plan, Fig. 5, and a 42-in. multiple punch for beams is soon to be installed. Material is supplied to the shop by way of six standard-gage tracks entering the landward side of the layout shop from the storage yard. The bridge cranes of the layout bay take material from the cars as delivered from storage, and transfer it as needed for laying out, straightening, etc. They deliver the material finally to the roller beds, the furnaces, or the hoist trolleys in the shape section. The extension of the shop now under construction will be equipped with a very complete system of overhead trolley runways, carrying in part electric hoists and in part hand hoists, and connecting with three transverse runways now in service in the plate section of the shop. With this handling equipment, all facilities for the movement of material through the shop will be supplied. The trolleys and roller beds deliver the fabricated material to the edge of the assembly bay, where it is taken up by the bridge cranes traveling along that bay.

All assembly bolting and riveting, from floors and frame brackets to bulkheads, is done in the assembly bay. This has proved a highly satisfactory feature of the original plan, though the officials state that an assembly area of twice the size could be used to advantage. The two 10-ton cranes in this bay suffice for handling assembled parts up to 20 tons in weight. This is enough to take care of all bulkheads (riveted up in half widths) except cofferdam bulkheads, which, with their stiffening girders, are assembled in the space between the shop and the head of the way.

Referring to the sketch plan, Fig. 3, it will be seen that there is a track along the outgoing side of the assembly shop and spur tracks leading out under the crane trestles along the shipways. These were laid out with a view to distributing much of the ship and other construction material down along the berths by railway cars, but the tracks have been used very little for such service, the bridge cranes proving ample for all handling.

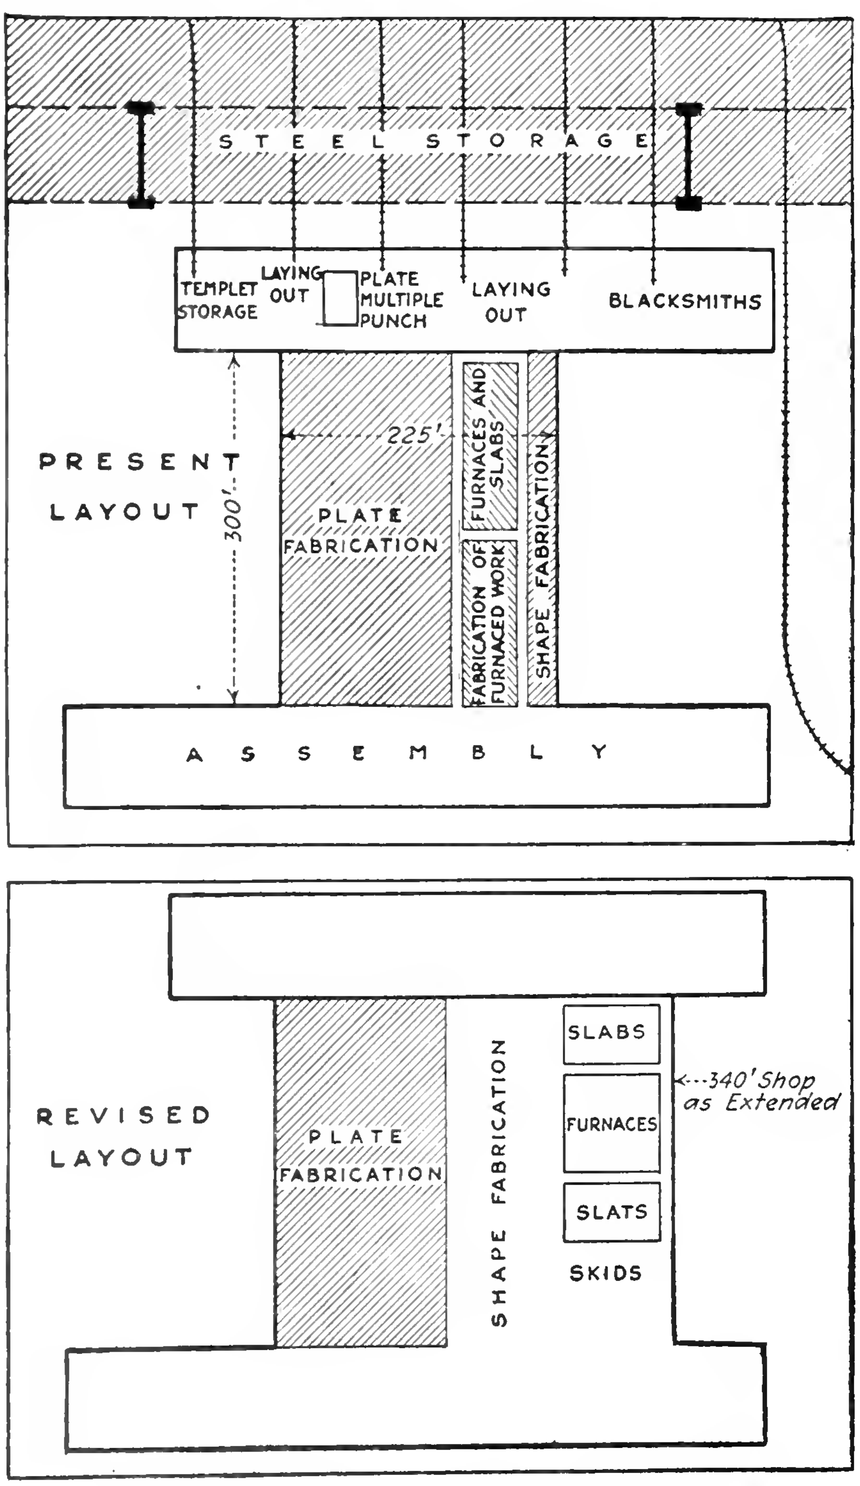

FIG. 5. EXISTING AND REVISED LAYOUTS OF FABRICATING SHOP

FIG. 6. ROLLER BEDS FITTED IN LARGER PART OF PLATE SECTION OF FABRICATING SHOP FOR EASY TRANSFER OF PLATE

Two Cranes Per Shipway—How the berths and cranes are arranged may be gathered from the view, Fig. 6, and the sketch, Fig. 7. The trestles are spaced 115 ft. on centers, allowing for an 80-ft. width of shipway, a trestle width of 15 ft., and 10 ft. of clear space between shipway and trestle. The trestles are built of towers 15 x 25 ft. in plan, spaced 50 ft. apart, so that the crane runway spans are alternately 25 and 50 ft. Each tower bent carries, by means of a transverse 30-in. girder, two crane run girders spaced 3 ft. apart and braced together for lateral stiffness. The crane girders in the tower spans are 30-in. I-beams, while the intermediate spans are 6-ft. plate girders.

The design of the shipbuilding crane runs, which is distinguished by the use of single H-sections for the columns and heavy sections for beams, up to 30-in. 200-lb. rolled girders for the transverse supports of the crane girders, was carried out by the Belmont Iron Works. The same concern designed and built the structure of the fabricating shop.

Small Way-Head Storage—Fabricated material completed in the shop—whether punched or assembled—is in part retained in the shop until wanted on the ship, and in part placed in storage at the head of the ways and alongside the crane trestles. The original intention was to take care of all this storage alongside the trestles, using the space at the head of the ways only for large assembly work, such as that of the cofferdam bulkheads. It has been found more convenient, however, to provide racks and stow material at the head of the ways, in small amounts. The heavy bulkhead assembly is carried on in this space, and stowage possibilities are therefore limited. It is expected that the way-head storage and supplementary storage along the trestles will provide for all requirements of equalization between shop and ship.

Reinforced-Concrete Berth Construction—What is virtually a copy of timber pile bent way construction was adopted by J. N. Pew, president of the Sun Shipbuilding Co., who is responsible for the principal features of the yard layout and construction. The Raymond Concrete Pile Co. designed and built the ways. Some essential details are shown in Fig. 8.

Over each pile a concrete column was molded. Transverse caps over the column bents, 80 ft. long over all, are connected by three longitudinal stringers near the center, and a spacer stringer along either side of the way. The center stringers are in the line of the keel blocks and the two launching ways. The transverse section in Fig. 7 makes their construction clear. For the rest, the bents are separate and wood flooring is placed over the caps to form a working surface. As the flooring is not fastened to the concrete the planks can be removed and replaced at any time.

At the site the present surface is all hydraulic fill. There was water over much of the present yard area at the time construction commenced. Hard bottom is found 25 to 45 ft. down, however. The piles were driven to a firm bearing in this. They were placed to develop a carrying capacity of 30 tons, or 50 tons at ½-in. settlement, but H. G. MacNees, plant engineer, believes that they would develop a 50-ton capacity with no appreciable settlement. The entire way structure

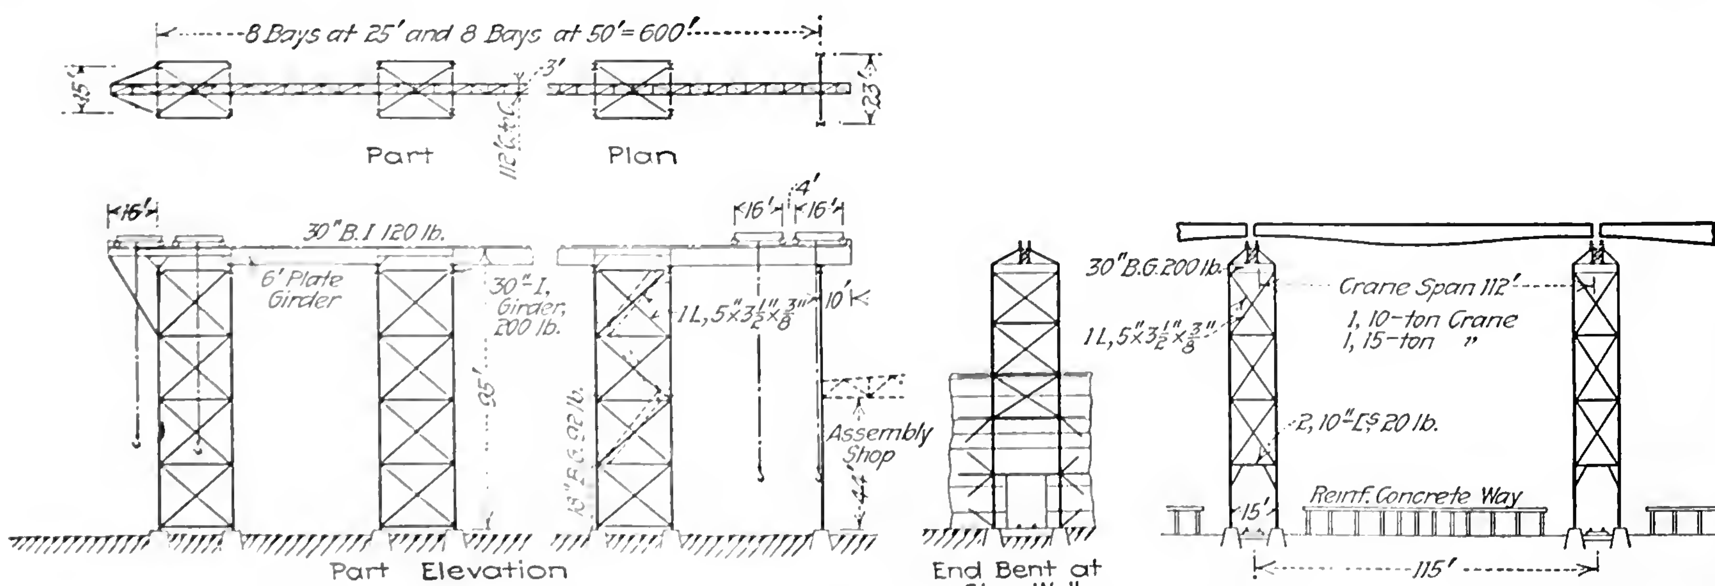

FIG. 7. SKETCH OF CRANE TRESTLES AND BERTHS

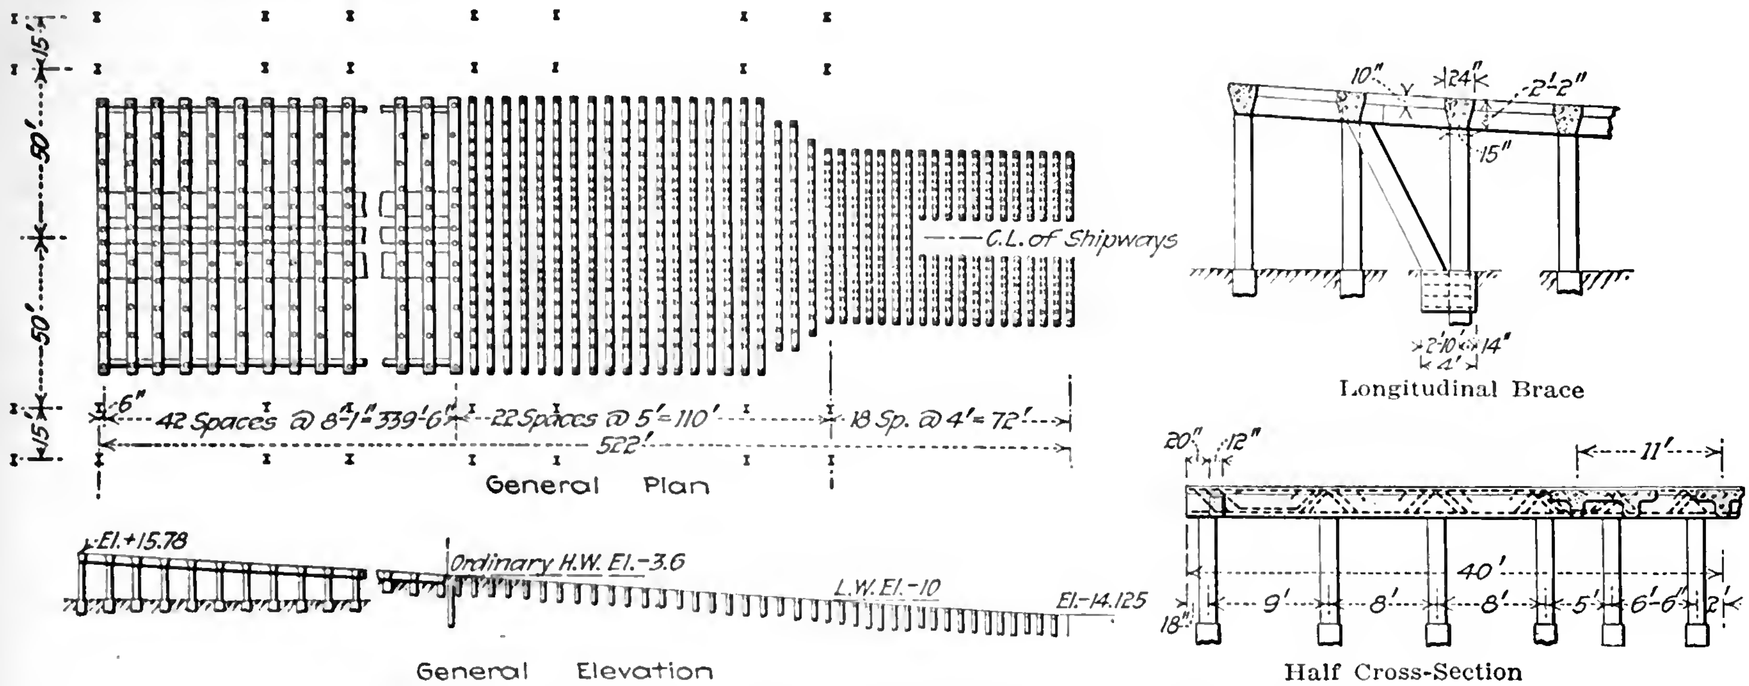

FIG. 8. CONCRETE PILE-BENT SHIPWAYS AT THE SUN SHIPYARD

is set on an $\frac{11}{16}$-in. slope, this inclination being the launching slope.

Excellent service has been given by these berth structures. No damage or settlement of any kind has been noticed. The principal change that has been made is the addition of a short timber platform blocked up directly on the ground, at the head of the ways, to form an extension for a longer ship than could be accommodated by the ways as originally built.

From high-water level down, the ways are wholly of timber construction, and consist of separate transverse bents of piles spaced 5 ft. on centers, for a total length of 182 ft. outward of the lowest concrete bent.

Storage Yard Rearranged for Bridge Crane Service—As originally planned, the area back of the fabricating shop was to be used for storing raw steel by flat piling on mud sills, the material to be handled by locomotive cranes from cars into storage and from storage into shop. A year's experience with this system made flat piling appear unsatisfactory, and racks were built. The final working out of the rearrangement is represented at present by a complete rack system covered by a bridge-crane runway spanning 80 feet and 800 feet long.

The standard rack developed for this yard consists of a 12 x 12-in. base timber to one side of which are bolted 6 x 4-in. angle standards, spread about 24 in. at the bottom and about 10 in. at the top, where they are conected by a gusset plate. These standards are stiffened by a short length of 8-in. channel at mid height. No longitudinal connection between parallel members of the rack is used.

Wet Dock Being Duplicated—The present wet dock is an excavated basin, 200 x 600 ft., walled by concrete retaining walls on pile-supported timber platforms. It is served by a fixed McMyler-Interstate hammer-head crane of 120 tons capacity. The machine is fitted with an auxiliary hoist of smaller lifting capacity. Engines and boilers (Scotch) are set in the ship here. The hammer head crane does all minor handling at the fitting-out dock also, no other lifting machines being provided.

To increase the dock capacity, a second basin, 100 ft. shorter, is now under construction immediately to the west. This will be served by a locomotive crane on portal base, of light load capacity but with fast motions, for handling general fitting-out work. The heavy lift will still be handled at the hammer-head crane, as described. The Sun Shipbuilding Co. was formed as an offshoot of the Sun Oil Co., whose main plant is only a few miles farther down on the Delaware River. Building large tank steamers for the oil company was the principal business at the start. Orders soon came for large cargo steamers, however, and the present program of construction at the Sun yard includes mainly cargo steamers. As already stated, the yard was planned and is being operated as a specialist institution for vessels of about 10,000 tons. For 1919 the intention is to work the yard at a rate to produce 18 ships in the twelve months. This means a building time of 100 days per ship. Such a rate of working could now be realized except for the fact that the fabricating shop has not reached full output capacity.

FIG. 9. ONE OF THE CONCRETE WAYS JUST AFTER CONSTRUCTION WAS COMPLETED, BEFORE PLANK FLOORING WAS PLACED ON CRANE RUNAWAYS

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

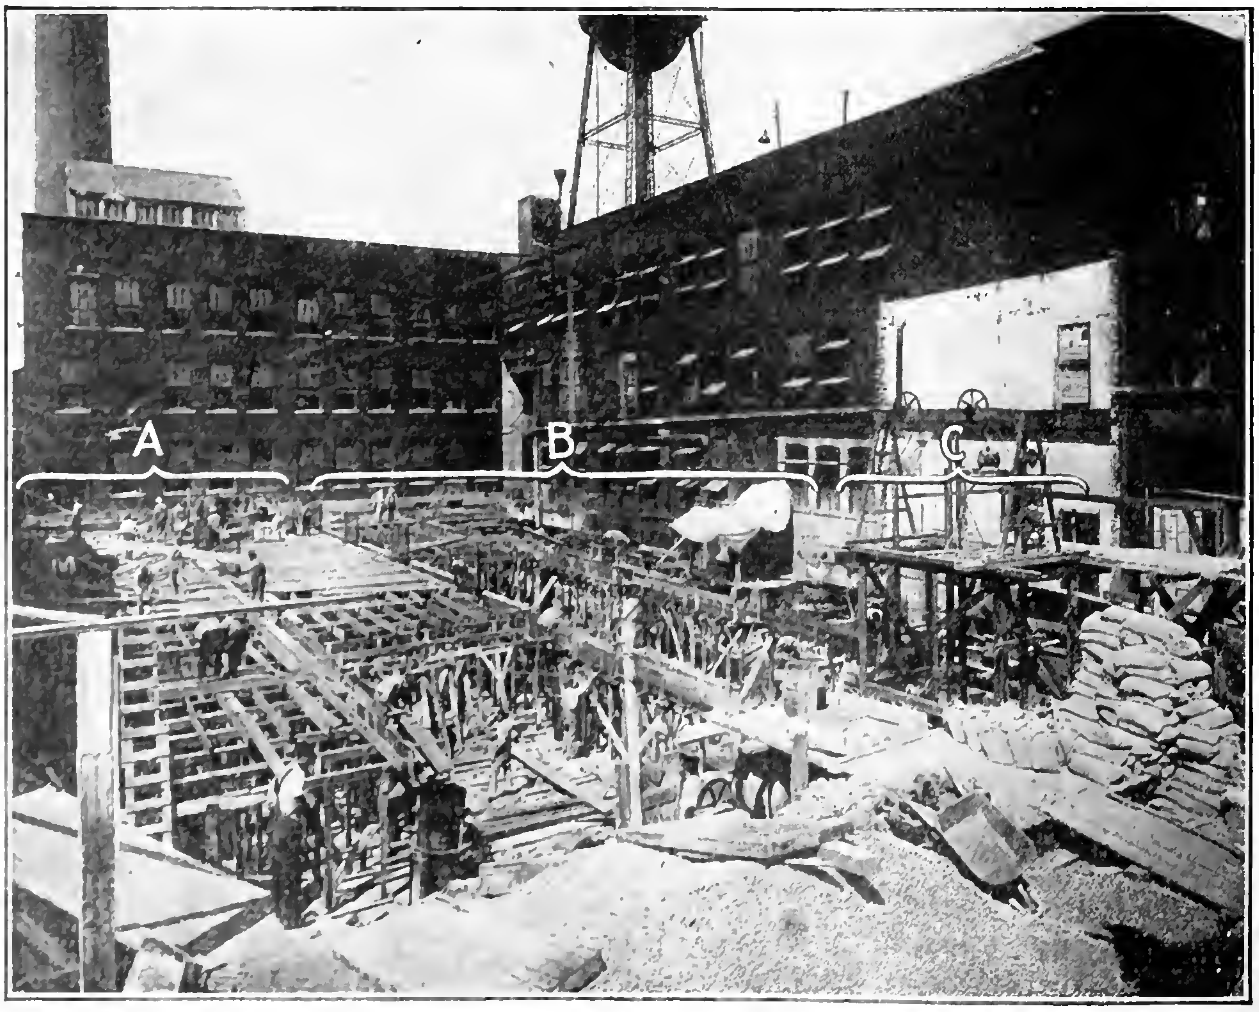
Close Sequence of Operations Cuts Construction Time

Caissons for War Work Factory Started as Soon as Steam Shovel Clears Sites—Construction Crews Scheduled to Crowd Each Other

CREWS purposely scheduled to crowd close on each other's heels were employed to speed construction on a concrete factory recently completed in Chicago. Occasionally, a crew was started even before work was ready for it, so as to increase the progress of the crew ahead. Clamoring for right-of-way, the concreting gang pushed the steel men and the steel men crowded the form carpenters, and behind all drove the contractor, with materials supplied and construction plans laid out well ahead of the best speed the workmen could reach.

War contracts required the completion of the building in four months. The ground dimensions were 108 x 76 ft. and the height was seven stories. The foundations were 24 open caissons sunk to rock at a depth everywhere less than 50 ft. Square outside columns and round interior columns carried longitudinal girders, between which were concrete joist-and-tile-fill floors of the Johnson type. A two-story building occupied the site. This had to be removed and a basement excavated. The work was let for a lump sum. Labor supply was the great problem, since war industries were offering workmen bonuses and unlimited overtime on percentage jobs.

Close sequence of operations was the plan devised to meet the speed requirements. As soon as a corner of the old building was wrecked, a steam shovel started excavating the basement, and as soon as the steam shovel had cleared sufficient space a single caisson was started. Caisson sinking proceeded by usual methods, except that, owing to quicksand and water, a large part of the lagging had to be driven and the wells were driven one at a time, using a hand windlass, as fast as the shovel cleared the site, instead of waiting until the general excavation had proceeded far enough to allow an engine to be rigged up to carry a number of wells at once. By this plan, the caisson work kept close behind the shovel, and the foundations were finished in prac-



FLOOR CONCRETING BEGUN BEFORE LATEST FOUNDATION CAISSON WAS FINISHED ON CHICAGO FACTORY

A. First-floor girder being poured in this corner, by use of temporary portable mixing plant. B. Form building and steel placing in all stages of progress proceeding in space between. C. Last foundation caisson being sunk in this corner.

tically the same time as was the general excavation. As fast as the caissons were ready, the foundation girders under the basement floor were concreted. At the same time, the adjacent building was shored. Retaining wall work followed as rapidly as the way was cleared for the forms. As shown by the view, slightly over one month after construction was started the old building was wrecked, the general excavation was completed, all but one caisson had been excavated and concreted, the foundation girders and the retaining walls were finished, concreting was in progress on the first floor girders, and column steel and floor forms were in various stages of erection. The view shows how close the sequence of operations was. It shows the last caisson being sunk in one corner, and the first floor slab being poured in the other corner. The procedure outlined saved two or three weeks' time at the start of the job.

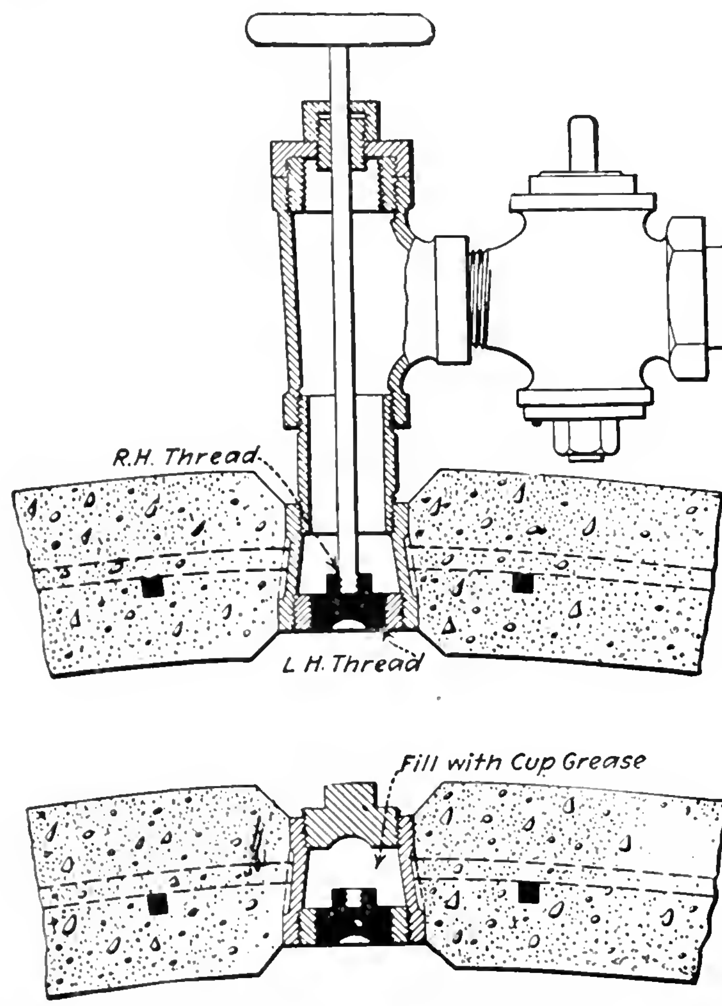
It was decided to handle the concrete by spouting from a tower at the end of the building to a hopper at the center of each floor, and to deliver the concrete from the hopper to the forms by carts. The ¾-cu.yd. mixer for the tower plant was used first for concreting the caissons, and was busy on this work until after the first floor concreting was begun. A small portable mixer was, therefore, installed temporarily to concrete the first floor and the retaining walls until the larger machine was free and the tower could be erected and the spouting strung.

Concreting of columns and floors followed the same close sequence as characterized the operations on the foundations and basement. As soon as carpenters had a section of floor forms ready, bridgemen were started laying steel and masons placing tile, and the concreting gang followed close behind. Each crew was kept close on the heels of the crew ahead, crowding it to get it out of the way. Often a gang was started even before the gang ahead was ready for it to take up the work. The fact that the job was war emergency work was kept constantly before the men. Constant pressure on the workmen by the means outlined was the secret of the progress made.

The building was designed by Holabird & Roche, architects, Chicago. Avery Brundage was the contractor. The contractor's superintendent was W. G. Nelson. Bauer & Black, Chicago, are the owners.

Service Connections to Concrete Water Mains

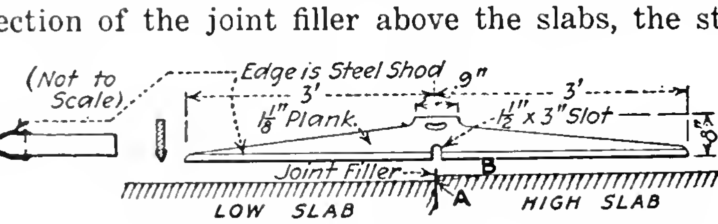
METAL pipe fittings, such as are kept in stock, can be used in making service-pipe connections to concrete pressure pipe for city distribution lines, by a device recently developed by the Lock Joint Pipe Co., Ampere, N. J. Malleable iron couplings are embedded in the original pipe when cast, as shown in the illustration. The inner end is fitted with a bronze plug inside of a malleable iron bushing. The outside end is fitted with a plug of malleable-iron, and the space between them is filled with grease. When everything is in readiness for connections, the outer plug is removed and the plug on the inner end is unscrewed by means of a stem inserted through a T, as shown in the sketch. The plug is then raised to and screwed into a faced bushing at the top of the T. The stem is unscrewed, along with the packing nut and perforated cap, and a solid cap is screwed on the faced bushing at the top. No tapping machines are required, and the excavation need be carried only to the top of the pipe.



REGULAR STOCK PIPE FITTINGS ONLY USED IN MAKING THIS CONNECTION

Split Straightedge Corrects Joint Humps In Concrete Pavement

HUMPS in a concrete pavement due to high slabs at joints are prevented in Wisconsin road work, according to F. M. Balsley, division engineer of the Wisconsin Highway Commission, by the use of the split straightedge shown by the drawing. Owing to the projection of the joint filler above the slabs, the strike board cannot be swept across the joint, and frequently, when it is lifted to start the next slab, exact elevation is not secured. The result is a high slab, as indicated by the drawing. Use of the split float at the joint will bring the edges of the two slabs to a common elevation, as at A, in the diagram, but there will still be a hump, as at B. The split straightedge, applied as indicated by the diagram, permits the detection of this hump or other irregularities in the planes.



STRAIGHTEDGE TO MAKE CONCRETE PAVEMENT JOINTS EVEN

The construction of the straightedge is simple. A 1⅛ x 8-in. plank is cut as shown, and the edge is beveled sharp and shod with sheet metal.

American Engineering Success in War's Test

Accomplishments by Engineers Cited to Rebuke Recent Utterances on Need for Training

That American engineers have succeeded in impressing the general public by the success of their work in the great war's crucial test is demonstrated by the comment of the Philadelphia *Public Ledger* in a recent editorial. This comment is so illuminating and informative that it is reproduced, as follows:

"This seems to be an odd moment for the recent pessimistic utterances of one of the professors at the Massachusetts Institute of Technology on the need of better training in all our engineering schools. For the fact is, not only have the professional engineers and their associates from West Point and Annapolis and all their amateur assistants who went into the Army and Navy covered themselves with glory in the war, but at this very moment, when the English University Commission has started back for home, its farewell opinion is more than usually flattering to American collegiate and university education. Moreover, what it particularly admired and marveled at was the splendid equipment of the technical schools and the physical laboratories in our larger institutions. In this it but confirmed English opinion as expressed in the friendly report of Alfred Moseley's unofficial commission, which made a survey of engineering training and practice in this country about a decade ago, a report that was a great tribute to the American trained engineer and to American schools.

"But if any confirmation of the value of the American engineer and of the technical training that has given him an efficiency recognized everywhere be needed, it will be found in Prof. William M. Sloane's brilliant account of his experience with the leading German magnates when he was one of our exchange professors. In his inimitable way, Professor Sloane has told how these German specialists fumed at the mouth because the American engineers were successful and beat the German engineers, when from the Prussian point of view, such a thing ought to have been impossible, since America was a wretched country, without standards of education and without individuals possessing any capacity for science or Kultur.

"Well, as the very modest recent report of President Vail, of the American Telephone and Telegraph Co., shows, in his discussion of the new

Wide Building Campaign Involving Billions About To Be Started by Government

"Build Now for Better America" Is Slogan of Department of Labor in Beginning Movement

(Washington Correspondence)

A great building campaign, involving the construction of highways, public works of other character, homes, and public utilities, is about to be undertaken by the Government, largely for the purpose of making certain that employment will be found for demobilized soldiers.

An organization to conduct the campaign is now being created in Washington, with headquarters at 16 Jackson Place, under the general supervision of Secretary Wilson of the Department of Labor, and with the coöperation of the American Federation of Labor and other labor interests. The following slogan has been adopted:

"Build now for greater and better America. A billion for roads; two billions for public works; three billions for a million new American homes. What are you doing to help this campaign?"

City Officials Urged To Build

The Department of Labor, as one of the first steps in the campaign, is sending the following message to wage earners throughout the country: "Use your influence with your city fathers, your selectmen and other town officers to start at once municipal and town improvement." Cities and towns are being urged to build school houses, engine houses, roads, canals and other improvements. To those who believe that the cost of building will be less in a few years than it is now, the Department of Labor is replying that "probably 95% of the cost of a residence ultimately goes to labor whenever a house is built, so that the cost is almost immaterial to wage earners as a class."

Secretary Baker of the War Department is coöperating in the campaign, and has sent telegrams to the Governors asking them to urge in inaugural messages the immediate resumption of building of every character.

One of the first branches of the new activity of the Government to be organized is the "Own a Home" branch, which has been placed under the direction of the Information and Education Service of the Department of Labor, of which Roger W. Babson is chief. Mr. Babson is creating an organization of assistants, headed by Franklin T. Miller of New York City.

One of the arguments being used in favor of the "Own a Home" movement is the figures as to increase of population. The population of the United States normally increases, exclusive of immigration, by 3,000,000 persons annually. At this rate the population is supposed to have increased by 6,000,000 during the past two years, during which the building of homes has been largely suspended. It is estimated that it is necessary to build 315,000 homes each year to meet increased housing needs, and that the building of 630,000 homes is necessary now. Secretary Wilson's statement is as follows:

"I am of the opinion that from the time we restore ourselves to our normal post-war activities, the demand for peace-time production will be so great that there will not be the remotest possibility of securing any reduction in the wage rates from their present basis. I feel further, that the manufacturer who fails to take into consideration the prospects of the future and who, in a hope of securing a cheaper labor or cheaper raw material, does not build up his organization and maintain it during the possibly brief period of readjustment, will be handicapped in securing his share of the business afterward; because he will be handicapped through lack of working forces in his factory.

"It therefore seems to me that the situation resolves itself into taking care of the possible problem in the interim between our ceasing war activities and the time when we have assumed our natural post-war activities.

Labor Reservoir Suggested

"With the attitude of mind that I have expressed as existing on the part of some manufacturers relative to waiting for a lowering in the price of raw material and the price of labor, it may be that the restoration of industry will not take place as rapidly as the demobilization takes place. We are not sure of that. There ought to be provision made for a reservoir that would absorb the demobilized workers and the demobilized soldiers, not in doing the things which there is no need to have done, but in doing the things that ought to be done—that are valuable for peace-time purposes—a reservoir that will take care of them for the brief period between their dismissal from the Army or their dismissal from the war

industries until they can be reabsorbed into the natural post-war industrial activities.

"The Department of Agriculture is taking steps to accomplish part of that purpose in the matter of road improvement, highway improvements, on the theory Congress has acted on in the past, that for military purposes and for postal routes roads are necessary all over the country. Where men are employed in road-building, they do not have to be taken from their own home communities to engage in the work. The Department of Agriculture, therefore, has asked or is about to ask for an increased appropriation which will enable it, in coöperation with the respective states, to engage in a nation-wide project of road-building that will absorb, if need be, some of these workers temporarily, until industry resumes its natural course.

"During the period of the war, because of the shortage of workmen, there has been little or no municipal activity in building operations, in park extensions, in sewer extension, waterworks, or any other of the public utilities. They have been delayed and postponed because of the shortage of manpower and because of the inability to finance them. We are suggesting, through the Department of Labor, to the various municipalities throughout the country, the advisability of their resuming these activities at as early a date as possible.

"Whenever it is possible to utilize public means, wherever it is possible to undertake public work, or things that are valuable for peace-time purposes, they should be undertaken as promptly as possible."

Colleges To Train Reserve Officers

With the demobilization of the Students' Army Training Corps, various colleges of the country will turn their attention to the Reserve Officers' Training Corps. Before the war there were about 115 units of the latter, in as many colleges. About 100 of these are being reëstablished and applications have been received for the formation of about 200 new units.

Secretary of War Baker announces one important change in the organization which is now being worked out to allow the units to specialize in training officer material for the field artillery, engineer, signal, coast artillery, ordnance, medical, and military aëronautics corps, instead of the uniform training for infantry, which was the rule before the war.

The administration of the Reserve Officers' Training Corps has been placed in the hands of the Committee on Education and Special Training. The committee will attempt to make available a large amount of scientific and technical material which has been developed by the experience of the war, and in all units special emphasis will be placed on physical training and mass athletics.

Government Concrete Ships Now Building

Owing to Cancellation of Some Contracts Big Ships Have Been Cut From 42 to 14

In *Engineering News-Record* of Sept. 5, 1918, p. 471, there was published a list of Government concrete ships then contracted for. That list has since been curtailed, so that at present the tabular statement represents Government concrete shipbuilding at the end of 1918. The cut is entirely in big ships. Instead of 42 vessels, mainly of the 7500-ton class, to be built in the agency yards, the Emergency Fleet Corporation is reducing contracts to 14, distributed as shown in the table. In addition, there are a number of barges under construction for private account, though there is no record of any private ships being built.

construction of the two tankers was started the latter part of October. About 30% of the steel has been placed. The inside forms have been made and partly erected. First concrete will be poured in January. The cargo ship will not be started until after the first tanker has been launched.

The San Diego yard is building two 7500-ton concrete tankers. Construction on these was started early in December. Outside forms are now practically completed, and some steel has been placed. The first concrete will not be poured until the latter part of January.

Two 7500-ton concrete tankers and one 7500-ton cargo ship are to be built at San Francisco. The construction on the two tankers was started the middle of October. The outside forms on both ships have been completely fabricated. About 60% of the steel

TABLE SHOWING GOVERNMENT CONCRETE BOATS UNDER CONTRACT

Government Agency	Type of Boat	No.	Name of Contractor	Location of Yard
Emergency Fleet Corporation	3500-ton Freighter	1	Fougner Concrete Shipbuilding Co	Astoria, L. I.
	3000-ton Freighter	1	Liberty Shipbuilding Co	Brunswick, Ga.
	3500-ton Freighter	2	Liberty Shipbuilding Co	Wilmington, N. C.
	7500-ton Tankers	2	San Francisco Shipbuilding Co.	Oakland, Cal.
	7500-ton Freighter	1		
	7500-ton Tankers	2	F. T. Ley & Co	Mobile, Ala.
	7500-ton Freighter	1		
	7500-ton Tankers	2	A. Bentley Sons	Jacksonville, Fla.
	7500-ton Tankers	2	Scofield Eng. Co	San Diego, Cal.
Navy Department	500-ton Harbor Lighters	4	Ambursen Consn. Co.	Little Ferry, N. J.
	500-ton Harbor Lighters	4	L. L. Brown Co	Peekskill, N. Y.
	500-ton Harbor Lighters	4	S. H. Beskin	Beacon, N. Y.
Railroad Administration (Construction Supervised by E. F. C.)	500-ton N Y Barge Canal Barges	8	Holler-Davis & Flood Co	Fort Edward, N. Y.
	500-ton N Y Barge Canal Barges	4	Caldwell-Marshall Co	Tonawanda, N. Y.
	500-ton N Y Barge Canal Barges	5	Grayhaven Shipbuilding Co	Detroit, Mich.
	500-ton N Y Barge Canal Barges	4	Cummings Structural Concrete Co	Ithaca, N. Y.
War Transport Branch, War Dept	130-ft River Boats	9	(Contracts not completed)	
	100-ft Water Tankers	5	Gt. Northern Sbldg. Co.	Vancouver, Wash.
	265-ft Car Floats	6	Liberty Sbldg. & Transp. Co.	Cleveland, O.
		6	L. B. Harrison Co.	Athens, N. Y.

The status of construction in the large ships is as follows:

At Wilmington, N. C., there are under construction two 3500-ton concrete cargo ships on molded lines. The yard, with two ways, was completed sufficiently to start the construction of ships about Oct. 15. The outside forms of one ship are practically complete, and part of the steel has been placed. On the second ship the outside forms are about 40% erected. There has been some delay in construction in this yard due to the change in the Shipping Board's program, which originally contemplated the building of both tankers and cargo ships in this yard.

The present program of the Shipping Board contemplates the construction of two 7500-ton tankers at Jacksonville. Construction work upon these two ships was started about the middle of November. The outside forms are practically completed on both ships, and some steel has been placed in both ships. The first concrete will be poured about Feb. 10.

At the Mobile yard the construction of two 7500-ton concrete tankers and one 7500-ton cargo ship is now contemplated by the Shipping Board. The

has been placed. The inside forms are built and partly erected. The first concrete will be poured in January. The construction of the cargo ship will not start until the first tanker is launched.

The Brunswick ship has been launched and the Fougner ship is nearly ready to launch.

The status of construction of the canal barges is as follows: Concreting has been completed on eight barges. Five are now in the water and 19 of the 21 under contract are either completed or under construction. Of the other boats, three of the Navy barges have been delivered, two of the Army car-floats have been poured, and one water-tank steamer has been poured.

Army Will Sell Horses and Mules

Contractors who need horses and mules may be able to get some cheap at auction sales of surplus animals to be held at the various camps and cantonments during January. The schedule calls for four sales, Jan. 7, 14, 21 and 28, at which a total of 44,455 animals will be sold. These will include cavalry horses, artillery horses, draft horses, mules and pack animals.

American Engineering Success in War

(Concluded from page 64)

multiplex device for 'phone and telegraph, the invention, one of the greatest ever made, was not the freakish discovery of one mind, but the result of the team work of hundreds of men on the company's technical staff. Not only that, but suggestions from men trained at Annapolis and West Point also proved helpful. In other words, the discovery was the result of the high equipment of the average American trained in the average school of technology or in that of trade experience. And one naturally mentions this multiplex discovery, since, taken in connection with the resourcefulness and initiative which mark so much of the college-trained, school-trained and shop-trained Americans on the battlefield in which they completely outclassed their German opponents, it is a feather in our cap and calls for some little reassurance, if not complete optimism, as to the American methods of the present.

"Moreover, the English engineer has also shown up well in war, although Germany despised the English experts for years and also had a poor opinion of the Frenchman's ability. And yet the English tanks, the French baby tanks, the French guns, to say nothing of the supreme French airplanes—and also not forgetting the Italian engineers and mecnanicians who reached an almost super-excellence—have all achieved wonders in the war and beat the Germans point by point in every line of action.

"The fact is, we must stimulate our own and we must increase our facilities for training engineers and for reaching down and connecting and gearing up the various engineering trades with the technical colleges and universities. But while it is quite right not to relax or fall back, at the same time we should take a little satisfaction in the evidence that the German system of education and the state-commanded scheme of a standardized universal Kultur has proved a failure so far as the question of developing men with initiative and individual resourcefulness is concerned. That our laboratories are likely to attract English students is another thing we can take to heart with comfort. Aside from this, it is clear that as civilization in the future will demand more of the engineer than ever, this demand our schools and colleges must meet. That they will no one can doubt. And as a sort of first instance, the recent reorganization of the Yale Graduate School, by which the Sheffield Scientific School and the Arts are grouped under a common head, with an increase of the undergradute scientific course from three to four years, is proof of the pudding."

Six Highway Bills Introduced in Congress During December

Besides the $1,000,000,000 highway bill introduced by Senator Smoot (as reported in *Engineering News-Record* of Dec. 26, p. 1198), five other road bills were introduced in Congress during December. While Senator Smoot's bill provided for a complete reorganization of highway administration by the Federal Government, the other bills aimed at utilizing present agencies and were either amendments to the present Federal-aid highway law or utilized the organizations of the War and Postoffice Departments. A joint resolution was also introduced, which provides for the handing over to the Secretary of Agriculture by the Secretary of War of such war material as may be used in highway construction work.

Senator Smoot's bill provides for the formation of a United States Highway Commission, to be composed of the Chairman of the Senate Committee on Postoffices and Post Roads, the chairman of the House Committee on Roads and the Director of the Bureau of Public Roads. It proposes to issue bonds to the amount of $1,000,000,000, the proceeds of which will be distributed to the states in proportion to the average percentage of their percentages of population, total assessed valuation, and total mileage of public highways. When money is supplied to the states, they must deposit state bonds, drawing interest at 4%, to cover the amount advanced to them. The 4% interest shall pay the 3% rate on the United States highway bond issues, and also establish a sinking fund to pay for these bonds. Long-time payments are provided for the state bonds. It is further provided that the Federal Government shall pay yearly to the depositing states 2% of the amount deposited, to be expended in maintenance.

Of the four bills providing for the utilization of the present Federal highway administration, those by Senator Bankhead, and Senator Swanson, in the Senate, and Representative Browne in the House of Representatives, are practically identical. They are in the form of amendments to the present Federal-aid highway law and consist of a change in wording to permit a wider interpretation of the words "post road," to cover any road that might so be used. They also provide for the appropriation of $50,000,000, to be immediately available; $75,000,000, available July 1, 1919; $75,000,000, available July 4, 1920; and $100,000,000, annually to July 1, 1924. Another bill, introduced by Representative Shackleford, provides for a similar change in wording and for an appropriation not to exceed $150,000,000 per year.

The other bill was introduced by Senator Swanson, and provides for the setting aside of 50% of the net proceeds derived from the operation of motor trucks engaged in carrying parcel post, to be expended in the survey, construction, reconstruction, improvement, repair, maintenance and administration of such highways as might be selected by the Postmaster General for the transportation of mail.

Criticisms of Chicago Paving Administration Retracted

Some time ago Prof. Ira O. Baker, of the University of Illinois, made a report on pavements in Chicago (see *Engineering News* of Dec. 7, 1916), which contained criticisms of the engineers and inspectors of the Board of Local Improvements. Some of the statements made in this report were shown on investigation to be based upon incorrect premises, and the following statement was obtained from Professor Baker of the Illinois Society of Engineers:

"Under date of Nov. 20, 1916, I forwarded to the Committee on Finance of the City of Chicago the manuscript of a report entitled "Report on Pavements Recently Built by the Board of Local Improvements of the City of Chicago." That report implied that there had been a considerable shortage in the thickness of all concrete foundations of pavements, and also in the thickness of the binder course and of the wearing coat of all sheet-asphalt pavements, which statements have been strongly objected to by the engineers of the Board of Local Improvements.

Pavements Examined Representative

"In preparing those parts of my report, I inquired specifically of the engineers of the technical staff as to whether or not the inspectors selected pavements of particular contractors, or pavements that were known to be faulty, and received an answer that convinced me that the pavements examined by the inspectors were fairly representative. I next inquired of the staff whether or not the summary of observations by the inspectors included all the observations made, and I was informed that they did. I asked for the inspectors' reports, and compared them with my report and found them to agree with the summary which the staff had furnished me.

"I had no reason for believing that my report was in error in any of these three matters, until I heard the testimony of one of the inspectors during the progress of the investigation conducted by a board appointed by the Chicago Civil Service Commission, Mar. 5-9, 1917. I then learned for the first time that, if the inspector found any defects in a pavement, he prepared a somewhat elaborate report from his field notes and filed that report; but, if he found no defects, he filed no report thereof. The data furnished to me were a summary of these special reports, and did not include any statement that other pavements had been inspected and found to be according to the specifications.

"All of my intercourse with the staff engineers convinces me that their only desire was to have the facts correctly presented, and I feel quite sure that they were entirely innocent of wrong intention in the matter.

"It is plain that as a number of observations were made and defects found

in only some cases, it was wrong to assume that the observations in which defects were discovered were representative of all the work done by the board during that season. I am very sorry that my report was not correct in these particulars; and am sorry to have made erroneous statements which have been considered as reflecting upon the honor of engineers of the Board of Local Improvements. I intended no such reflection.

"Public acknowledgment of the errors in my report has been delayed for a year and half on account of the fact that three investigations of the report have been pending. I believed, that, awaiting the outcome of these investigations, any statement concerning the matter by me might be considered as an attempt to forestall the verdict of the investigating body. I do not think that the delay in this acknowledgment has done any serious harm, since in the investigation conducted a year and a half ago by the board appointed by the Chicago Civil Service Commission I freely acknowledged my error, and since the findings of that board have been given wide publicity.

"IRA O. BAKER."

Louisville Club To Draft Bill For Licensing Engineers

The Engineers' and Architects' Club of Louisville, Ky., at its December meeting, unanimously passed a resolution providing that a committee of three be appointed to draft a bill licensing engineers and architects, and submit the draft to the board of direction. Then it is to be sent to every engineer and architect in the state of Kentucky of whom the committee can learn—including consulting engineers and architects and men holding salaried positions—with the request that the men addressed indicate whether they are in favor of licensing engineers and architects, and if so, that they suggest any desired changes in the bill as drafted.

The resolution also provides that the committee shall make such revisions in the draft as it may deem wise, submit it to the board of direction and then to the club, and, after approval, that a copy be sent to every member of the Kentucky legislature with the request that the bill be passed, and with a statement of the number of men in the state who expressed an opinion for or against the bill.

Rivers and Harbors Bill Reported

The current rivers and harbors bill, reported to the House of Representatives Dec. 21, contains items totaling $27,000,000, made up, practically, wholly of the usual project improvements. Large items are $4,000,000 for continuing the East River improvement at New York City, $2,500,000 for the Delaware below Philadelphia, and $3,000,000 for the Chesapeake & Delaware canal.

Wood-Preserving and Tie Men To Meet in St. Louis

The 15th annual meeting of the American Wood Preservers' Association will be held in St. Louis, Jan. 28-29. On the following two days a meeting of the tie producers of the country, to effect a national organization, will be held under the auspices of the tie and timber division, St. Louis Chamber of Commerce, in order to bring together both producers and users of cross ties.

In order to correlate the programs of the two bodies, the meeting of the American Wood Preservers' Association has been curtailed to two days, with three sessions on the first day and two on the second, concluding with a joint dinner with the National Tie Producers' Association. A session on the first day of the meeting will be devoted to consideration of the preservative materials situation, and a session on the second day to the tie problem.

War Committee on Technical Societies Handled Many Problems

As stated in the final report by D. W. Brunton, chairman, before its disbandment on Dec. 31, the War Committee on Technical Societies coöperated with the Naval Consulting Board and issued two bulletins, one on "The Enemy Submarine" and one on "Problems of Aëroplane Improvement." Before these bulletins on concrete problems were issued, only four-tenths of one per cent. of the matter received was adjudged by the committee of technical examiners to have sufficient merit to go before the final examiners of the Naval Consulting Board. Since that time the percentage has risen to 4.7%. The material received ranged from airplane superchargers and fuel for high altitude flying down to submarine detectors and depth bombs; from long-range guns to trench knives; from observation balloons to tunneling machines, and from caterpillar tanks to radium sights. More than 110,000 ideas, suggestions and inventions were received and passed upon by the Naval Department and the Naval Consulting Board, either separately or conjointly, while the Inventions Section of the General Staff, which is a much younger organization, has already handled over 25,000.

The inventions received may be roughly divided into four classes: (1) Those which have no intrinsic or suggestive value; (2) those which, while having no real value in themselves, suggest new lines of thought and investigations; (3) inventions which have considerable promise, but are not yet developed to a point where it is possible to pass judgment on them, and (4) inventions which are sufficiently perfected so that they can be investigated and tested. Ample facilities for testing inventions of the fourth class are provided by the Bureau of Standards and the Bureau of Mines, in Washington. The ideas, suggestions and inventions belonging to the second and third classes are, of course, much more numerous, and the necessity of providing some means for solving problems and developing inventions has long been apparent. In many instances, inventors have not the funds, the scientific knowledge or the mechanical skill to perfect their own inventions, hence aid in each of these directions is necessary in order that the country may reap the full benefit of the originality of its citizens.

Army Engineers Designated for Early Return

The War Department has announced that the following engineer units have been placed on the priority list for orders to return to this country:

Fortieth Engineers, placed on priority list Dec. 4, 33 officers and 623 men; 109th Engineers, Sappers, placed on priority Nov. 26; 311th Engineers and Engineer Train, Nov. 29, 57 officers, 1685 men; 312th Engineers, Nov. 26, headquarters, 24 officers and 29 men; headquarters company, two officers and 156 men; Co. A, three officers and 224 men; Co. B, five officers and 221 men; Co. C, five officers and 217 men; headquarters detachment, one officer and three men; Co. D, four officers and 245 men; Co. E, six officers and 237 men; Co. F, five officers and 241 men; 312th Engineers' Train, two officers and 74 men; 319th Engineers and Train, Dec. 4, four officers and 217 men; Co. E, four officers and 222 men; Engineer Casual Co. No. 1, Dec. 4, two officers and 223 men; Second Engineers, Dec. 6, Cos. F, I, K and Medical detachment, 20 officers and 760 men; Cos. D, E, G and H, 35 officers and 1000 men; 26th Engineers, Dec. 17; Co. A, eight officers and 253 men; Co. B, three officers and 181 men; 27th Engineers, Dec. 16, 46 officers and 1409 men; 29th Engineers, Dec. 12, headquarters detachment, two officers and eight men; Co. B, 14 officers and 238 men; Co. C, 11 officers and 185 men; Co. D, eight officers and 83 men; Co. E, 14 officers and 119 men; attached, three officers and 18 men; Co. F and detachment, 24 officers and 408 men; Engineer Casual Co. No. 1, Dec. 4, two officers and 223 men; 317th Engineers placed on priority Dec. 4, cancelled Dec. 16.

It was stated that the units generally arrive in this country from four to six weeks after being placed on the priority list.

New President for University of Wisconsin

Dr. Edward A. Birge was elected president of the University of Wisconsin Dec. 17 to succeed Dr. Charles R. Van Hise, who died on Nov. 19. Dr. Birge has been dean of the College of Letters and Science for the past 27 years, and a member of the faculty of the university for 43 years. He will assume the office of president at once, having been acting president since the death of Dr. Van Hise.

Notes From the Field

SOME OBSERVATIONS OF AN ITINERANT ENGINEER

In the issue of Dec. 5, *Engineering News-Record* told the story of the Spruce Production Division. The editorial tribute was well deserved, but I doubt whether the full spirit of that great job has been conveyed to the reader. I had the pleasure of seeing part of the railroad work on the Olympic Peninsula, one of the projects to which the article makes reference. I have never seen a job that for spirit and organization impressed me so favorably. One of the best railroad contractors said it could not be done in a year. It was completed in six months. Soldiers as well as civilians formed the working crews. Three shifts there were, and as one man laid down his pick, or quit his place, his successor took up the work—took it up immediately, with not ten minutes', not one minute's delay. Lunch was carried to the line to save time.

If the work was under high pressure, there was full compensation—good wages, model camps, excellent food. Throughout were enthusiasm and an unbeatable determination to put the job through.

Sometime all the men who were concerned with this great work will receive adequate credit. I wish I could name them, but I would have to start with the chief engineer, Mr. Kelliher, and the Siems-Carey Co., the general contractors, and continue down till I had named the last contractor's foreman.

And then, to be fair, I would have to go to each of the other Spruce Division's operations.

A great job, and I shall not soon lose its inspiration.

Linked with the memory of the job, too, are the hospitality of my hosts, Palmer, Pearson & Woods, one of the subcontractors, and the wonderful scenery of Lake Crescent, its waters rivaling those of Lake Tahoe and being reminiscent of the Italian lakes, its scenery recalling Champlain and George.

Last week I met two young engineers who have secured a return from a certain investment of time while in college that is well worth recording for the benefit of other engineers. They took courses in public speaking.

One of them, engaged in highway work, has made as rapid progress as any young engineer I have ever met, and he is pointed toward a great success. He recently played an important part in a bond-issue campaign, both through writing and speaking. To a large extent he attributed his rapid progress to the recognition that has come to him through his ability to speak in public.

The other young man, out of school only three and one half years, has built up a large acquaintance in his specialty — technical advertising — an acquaintance of direct and constant value to him in his work.

These men are at the entrance of their careers, but already they are beginning to reap returns from their ability as public speakers. As years go by and they talk from fuller experience, their speaking asset will develop in value in a rapidly increasing ratio.

Training and practice in public speaking are to the thinking man not merely exercises in overcoming bashfulness, though they are hardly more than that for the man who deals in platitudes and spread-eagleism. For the thinking man public speaking is a training in clear thinking and concise exposition. Success as a public speaker comes from having something worth while to say and saying it clearly and forcefully. The young engineers in question have not merely overcome stage fright. They have schooled themselves to analyze questions thoroughly so as to disclose the essentials, and have learned how to present these essentials effectively.

And the important things are yet to be said:

A little training in public speaking goes a long way;
It is never too late to learn.
Moral: *Go to the nearest Y. M. C. A. or similar institution and find out when the next course begins.*

E. J. M.

Aid for Highway Bridge Projects To Be Considered

Recent steps taken to organize a committee of bridge engineers as a Division of Bridges of the National Highways Association will be supplemented by a meeting of the committee Jan. 17 in New York City. A tentative outline of the program of work which this committee will undertake includes consideration of the subject of highway crossings over large rivers, advice and assistance in the broader preliminaries of highway bridge projects, and related matters in which special knowledge of bridge engineering may be made of service to highway development. The division will carry on its work on the principle of taking the initiative in any particular case only when called upon to do so. The functions of the committee are planned exclusively for service to the public good. Further development of the program of future work is expected to come about through the meeting on Jan. 17. G. Lindenthal is chairman of the division, and C. E. Fowler is secretary.

Promote Large Bond Issue for Missouri

A bond issue for $50,000,000 will be proposed for the building of public roads in Missouri, and will be urged upon the state legislature at the coming session by the Federation of Missouri Commercial Clubs. It is proposed to raise the funds for this construction, both principal and interest, from the motor-license tax.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 West 39th St., New York City; Jan. 15-16, New York.

AMERICAN WOOD PRESERVERS' ASSOCIATION: F. J. Angier, Mt. Royal Station, Baltimore, Md.; Jan. 28-29, St. Louis.

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

NATIONAL RIVERS AND HARBORS CONGRESS; 824 Colorado Bldg., Washington, D. C.; Feb. 5-7, Washington, D. C.

The Engineers' Club of Philadelphia will hold a joint meeting with the Society of Automotive Engineers Jan. 21, at which G. Douglas Wardrop, editor of *Aërial Age Weekly*, will present a paper on "War Aviation in Retrospect; Commercial Aviation in Prospect," illustrated with motion pictures and lantern slides. Mr. Wardrop will speak on his experiences in the war zone, including his participation in bombing expeditions and observation of aërial battles. Dr. Grover G. Huebner, University of Pennsylvania, will speak on "The American Merchant Marine" at the weekly luncheon Jan. 7.

The County Surveyors' Association, the County Road Superintendents' Association and the State Highway Commission of Indiana will meet at the fifth annual road school of the School of Civil Engineering, Purdue University, Jan. 7 to 9, 1919. Important highway developments are under way and need the coöperation of all officials and others interested in road problems, it is announced. Prof. R. C. Yeoman, of Purdue University, Lafayette, Ind., may be addressed for programs and information.

The Nashville Engineering Association was addressed Jan. 21 by J. F. Walters, Nashville, Chattanooga & St. Louis Ry. on "Railroad Water Supply." Dr. C. R. Mann's recent report on engineering education was discussed by J. P. W. Brown. The annual meeting and dinner of the association will be held Jan. 6.

The New England Water-Works Association will hold its annual meeting in Boston Jan. 8. The meeting of the executive committee on the morning of Jan. 8 will be followed by a luncheon at the Hotel Brunswick, and reports of officers and committees will be received in the afternoon. Among the committee reports to be presented are the following: "Standard Specifications for Cast-Iron Pipe"; "Statistics of Water

Purification Plants"; "Proposed Standard Schedule for Grading Cities and Towns of United States with Reference to their Fire Defences and Physical Conditions," and "A National Water Law."

The Western Society of Engineers' nominees for office to be voted on before Jan. 17 are as follows: For president, D. S. Baldwin; vice-presidents, Kempster B. Miller, William M. Kinney and J. L. Hecht; treasurer, C. R. Dart; trustee for three years, E. T. Howson. Herbert C. Hoover has been named as recipient of the Washington Honor Award presented by the society for the first time. It was founded by John W. Alvord for meritorious public service. The presentation will be made at the society's Washington Birthday meeting. The annual meeting will be held Jan. 22 at the Sherman Hotel, Chicago.

The Engineers' Club of Trenton, N. J., was addressed Dec. 30 by W. W. Colpitts, who read a paper on "Some of the Questions Involved in Determining the Compensation Due the Railroads While Under Government Control."

Personal Notes

MAJ. EDWARD C. SCHMIDT, Ordnance Department, U. S. A., previously professor of railway engineerign, University of Illinois, who was temporarily assigned to service with the United States Fuel Administration as assistant to the manager of the Fuel Conservation Section, has returned to service in the War Department.

WILLIAM B. LANDRETH has been named chief of the board of consulting engineers, New York State Canal System, succeeding Joseph Ripley, who has resigned to undertake irrigation and canal work in China. Mr. Landreth has been connected with the canal system of the state for many years and has served as deputy state engineer during the administrations of State Engineer Williams.

T. C. HUGHES, Tulsa, Okla., has been appointed consulting engineer to supervise the construction of hard-surfaced roads to be built by Tulsa County, under the $1,700,000 bond issue voted last year. He will coöperate with D. W. Patton, county engineer, who will be engineer of construction.

J. S. DODD, assistant road engineer of the Iowa Highway Commission, who has been taking the place of Maj. T. R. Agg as professor of highway engineering, Iowa State College, during the absence of the latter in the Army, has resigned and has returned to his duties with the commission. Major Agg has reassumed his teaching duties as professor of highway engineering.

H. T. SYMPSON, assistant division engineer, Eastern Division, Pennsylvania Lines West, with headquarters in Pittsburgh, has been appointed division engineer at Columbus, Ohio, succeeding G. R. Barry, promoted to division engineer, Chicago Terminal Division, as mentioned elsewhere.

GEORGE WESTON, assistant chief engineer, Board of Supervising Engineers, Chicago Traction, has resigned to become consulting engineer for the Philadelphia Rapid Transit Company.

W. J. ECK has been appointed signal engineer, Southern Ry. and associated lines, with headquarters in Washington, D. C.

V. I. SMART, formerly professor of railway engineering and transportation, McGill University, and J. A. Burnett, formerly electrical engineer, Grand Trunk Railway System, are now associated as consulting engineers, with offices at 821 New Birks Building, Montreal.

G. R. BARRY, division engineer, Pennsylvania Lines West, Columbus, Ohio, has been appointed division engineer, Chicago Terminal Division, Pennsylvania Lines, succeeding F. M. Graham, who was appointed supervising engineer, Southwest System of the Pennsylvania Lines, with offices in Columbus, as mentioned in *Engineering News-Record* of Dec. 12, p. 1102.

J. D. NEVILLE, county engineer of Lewis County, Washington, has been appointed division engineer of the southwest Washington counties for the Portland Cement Association.

HARLEY W. BRUNDIGE, Los Angeles, and Irving Martin, Stockton, Cal., have been appointed by Governor Stephens of the State Railroad Commission. Harry D. Loveland has been reappointed for another term.

MAJ. CLARK R. MANDIGO has returned to his duties as consulting engineer, Western Paving Brick Manufacturers' Association, with headquarters in Kansas City.

ROY J. FINCH, who for some years has been chief clerk of the New York State Engineer's office, has been appointed deputy state engineer to succeed William B. Landreth, who has been appointed chief of the board of consulting engineers, as mentioned elsewhere. Mr. Finch, a graduate of Rensselaer Polytechnic Institute, has been connected with the State Engineer's office since 1908, serving as supervising engineer and division engineer before taking the position of chief clerk.

ROSWELL M. ROPER, for the past year acting engineer for the water department, East Orange, N. J., has been appointed engineer of the department.

Obituary

CHARLES E. PHELPS, former chief engineer for the Public Service Commission of Maryland, whose death was noted in these columns last week, was born in 1871 and received his first technical training at Johns Hopkins University in 1891-1893. In 1902 he was retained by the City of Cleveland to report and estimate upon the cost of an electric street and commercial lighting project adopted by the city council. In 1903 he was retained by the cities of Johnstown, N. Y., and Rochester, N. Y., in litigation over the construction and operation of underground electric conduit systems, and by the city of Montreal to report and estimate upon an underground conduit system project. Two years later he was retained by the City of New York to assist in the investigation of charges for electric street lighting. Later he became chief engineer for the electric commission of the city of Baltimore, and was in charge of the construction of underground conduits. He also served as secretary of the Municipal Lighting Commission of Baltimore and as a member of the Sewerage Commission. In 1910 he became chief engineer for the Public Service Commission of Maryland, and five years later was appointed to the Maryland State Board of Health as engineering member.

GEORGE ALEXANDER JUST, president of the George A. Just Co., contracting engineers, Long Island City, N. Y., died Dec. 27 in New York City. He was born in 1850 and was a graduate of Rensselaer Polytechnic Institute. At one time he was associated with Cooper, Hewitt & Co. He had been in charge of the erection of many buildings in New York City.

DOUGLAS W. TAYLOR, formerly city engineer and superintendent of streets, Portland, Ore., died in that city Dec. 12, at the age of 68.

KARL A. FUNK, structural engineer, who for the past few months had been associated with the Deslauries Aircraft Corporation, Newark, N. J., died Dec. 11 in that city. He was graduated from the Massachusetts Institute of Technology in 1912 and had been in charge of the construction of several buildings in Boston.

Converts Waste Marble Into Valuable Byproduct

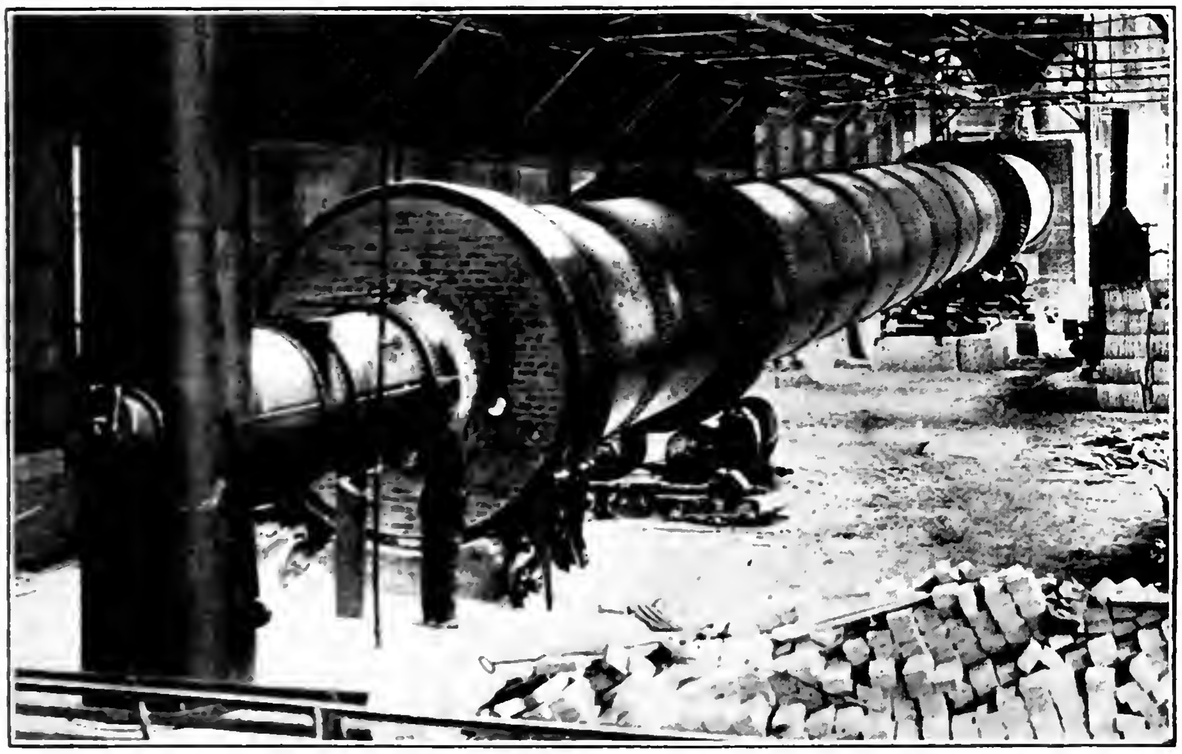
Vermont Company Now Produces Lime from Culls and Chips Formerly Discarded as Useless

During the past four years a large New England marble company has been experimenting with the stone usually wasted in its yards, with a view to converting it into a byproduct. Three years ago experiments were made on different grades of marble to determine the amount of lime obtainable by burning. The tests resulted in the company's building a modern well-equipped lime plant.

The raw material, as it comes to the plant, is in miscellaneous sizes. Blocks over 12 in. thick are conveyed in slings to a 60 x 48 jaw crusher, from which the material is conveyed by gravity through a gyratory crusher set to reduce all the material, including the sizes not sent through the jaw crusher, to 2 in. or less. The material is then elevated and screened, the screened product passing through a set of 36 x 16-in. rolls to reduce it to ½ in. or less. All of the material is then elevated and conveyed into storage or kiln bins, from which it can be drawn at any desired time.

The material from the kiln bin is sent into the kiln by a feeder. The kiln is patented after the familiar cement design, 8 ft. in diameter, 20 ft. long, installed with a 4% pitch. It is belt driven from a 30-hp. variable-speed motor, geared to give 10 ft. from 0.5 to 1.5 revolutions per minute, as desired.

The producer gas is introduced through a flue into the lower end of the kiln, and in burning furnishes the heat for calcining the stone as it gradually rolls through the revolving cylinder. A temperature of 2200 deg. F. is maintained, which drives off the CO from the stone, leaving the quicklime. The hot lime drops from the lower end of the kiln into a revolving cylinder, where it is cooled by the draft of air on its way into the kiln to support combustion. The cooled lime is elevated from the discharge of the cooler and is then deposited in lime-storage bins.



ELECTRICALLY DRIVEN LIMEKILN

Reduction of Labor Shortage Reported by Department

That the supply of labor is rapidly meeting the demand is indicated in a report received from the Department of Labor. The information in the bulletin, the department says, is received by telegraph from local representatives of the Federal Employment Service, and is used in making replacements, in allocating labor, in the curtailment and cancellation of war contracts, and in the demobilization of the Army. The bulletin shows that there is a surplus already in the Middle West, West and Far West, mostly in the cities, and some slight surplus in certain lines is reported from Boston, Buffalo and Rochester, as well as from Nashville, Tenn., and cities farther south. The greatest surplus reported, in Dayton, Ohio, amounts to 5000. The New England States generally report the supply and demand about equal, as do some of the Middle Western States and the South generally. Los Angeles, Cal., also reports the demand about equal to the supply.

Most of the shortage appears to be in the Atlantic States, from Connecticut to Florida. The greatest, amounting to 15,000, occurs in Philadelphia, but is 10,000 less than is shown in the preceding report. Although there are shortages in the manufacturing cities of eastern Ohio, the report states that they are reducing rapidly. Pittsburgh, Harrisburg, Scranton, Allentown and South Bethlehem, in Pennsylvania, all report shortages, more or less in amount, as well as the southern cities of Atlanta, Louisville, Baltimore, Lynchburg, Norfolk and Chattanooga.

Record Non-Stop Tractor Run

A run of 480 miles from Peoria, Ill., to Detroit, Mich., in six days, was recently made by a caterpillar tractor. This is said to be a record for tractors, and to mark a new milestone in tractor progress.

The tractor, which was of the 85 hp. Holt type, was delivered to representatives of the United States Government, and the run was made in the nature of a test of the machine. It followed highways of all kinds, many in very bad condition, and although the speed on road is rated at three miles an hour, it did a little better, covering the distance in 151 hours. Despite the bad roads, however, the tractor was in such good condition at the end of the run that it was immediately ordered overland to the Army Proving Grounds at Aberdeen, Md. There were no mechanical breakdowns, and inspection showed the machine to be in excellent condition.

Business Notes

The Maxwell Engineering Co., formerly at 156 Twenty-fourth St., Brooklyn, N. Y., is now completing its new yard, plant, and office building at 103 Thirteenth St., Brooklyn.

The Carbo Steel Post Co., formerly of Chicago Heights, Ill., has changed its address to 2600 West 111th St., Chicago, Ill.

The Chicago office of the Electro-Bleaching Gas Co., 11 La Salle St., which was temporarily closed on account of the war, is to reopen, and will be in charge of G. R. Ellis, as formerly.

Trade Publications

The Raymond Impact Pulverizer Co., Chicago, Ill., has issued catalogue No. 13, covering its equipment of roller mills and pulverizers equipped with air separation for grinding all kinds of materials to powdered form.

"Steel Pile Forms" is the title of bulletin No. 12-A issued by the Northwestern Steel & Iron Works of Eau Claire, Wis., builders of engines, concrete mixers and steel forms. It is an 8 x 10 twenty-page pamphlet illustrating and describing the product of the works.

The Milliken Brothers Mfg. Co., New York City, has issued a 23-p. 6 x 9 ½-in. booklet entitled "Space and Speed in Steel Buildings," describing the standardized truss unit system of building construction designed and manufactured by the company.

A Consolidation of Engineering News and Engineering Record — McGraw-Hill Company, Inc.—JAMES H. MCGRAW, *President*

ENGINEERING NEWS-RECORD

A WEEKLY JOURNAL
DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, *Editor* — CHARLES WHITING BAKER, *Consulting Editor*

Volume 82 — NEW YORK, THURSDAY, JANUARY 9, 1919 — Number 2

What Do You Want From Your Legislature?

THIRTY-THREE state legislatures meet this year. What do you, reader, want from yours in behalf of your city or state, the engineering profession, the returning soldier, or to better the relations between employees and employers, or to help solve the increasingly serious utility problems of the day? The question would be most appropriate for discussion before local and state engineering societies. Many of the latter will meet this month and next. Meanwhile, each engineer and contractor may well ask himself and his fellow, "What do you want from your legislature?"

Low Labor Costs With High Wages

OF THE two chief construction-cost factors, materials and labor, one is inflexible, the other flexible. Material prices are what they are, and there is no recourse. Wages are relative to what the laborer produces. Steel-erection costs in the vicinity of New York are very much lower today than they were ten years ago, *though wages have doubled.* The reason is simple: *The men are producing more per dollar of wage.* Labor leaders are recognizing that to maintain high wage levels production must come up in proper proportion. We know of one construction job on which labor leaders are working with the owner (in this case the Government) to bring up the admittedly large output per man. In consequence, costs have been reduced 30 per cent. as against what they were some months ago. With such a wage policy adopted generally by the labor unions, the labor costs, even with present wage scales, need not be above pre-war costs. Only high material prices would then remain to becloud the construction horizon.

Rural Development Urged by Governor of New York

IN HIS message to the legislature Governor Smith of New York has urged very strongly the coöperation of his state with the national Government in creating land settlements for soldiers. In doing so he heartily indorses the plans laid out by the Secretary of the Interior for coöperation between the Federal Government and the individual states. He well says: "It is becoming more and more apparent that the ability and the experience of our agricultural leaders should be mobilized to create a planned rural development which will include coöperative organization for buying and selling, a system of credit that will give broader opportunities for men of small capital to become farm owners, and a better social life." We have generally associated with Western conditions such rural projects as that so well described by the Governor, but every one familiar with rural conditions in the West realizes the need for well planned rural projects, even in the most thickly settled districts. Such projects would take advantage of all of the experience and experimentation which has resulted from Federal initiative or from successful local communities in every part of the country. The remarkable development at Durham, Cal., of the State Land Settlement Board is a pattern that can easily be duplicated if existing agencies are called upon for help. The entry of New York State into such a land settlement scheme would give an impetus for better agriculture throughout the entire East, and we sincerely trust, therefore, that the New York legislature will give attention to this feature of the Governor's message. While put forth principally as a reconstruction measure, it has promise of great influence as a peace-time measure.

War Control of Highways Here and in Great Britain

A COMPARISON of highway construction control in the United States and Great Britain during the war will be found elsewhere in this issue. It is written by an engineer who had close contact with the control work in this country and constant access to reports of the English Road Board's activities. His attitude toward the work of the United States Highways Council is quite favorable, while that of *Engineering News-Record* during the activities of the council was decidedly critical. There is all the more reason, therefore, why a hearing should be given to what may be interpreted as approximating the council's own view. Two points should be advanced in extenuation of the heavily restrictive activity of the council: First, that the narrowness of policy, the failure to recognize the war-function of highways, was due very largely to the attitude of one member of the council; and, second, that during the last month of the council's life there was marked progress in the direction of a more liberal policy. One man, it will be contended, should not have been able to hamstring the whole council; yet that was possible when the man in question held the whip hand—in his control over materials. In the matter of more liberal policy, the increase in the number of projects approved in the month before the signing of the armistice indicates that if the war had continued there is likelihood that the council's stand would have changed to full recognition of the highway's place in the war scheme. As it was, however, criticism lay heavily on the council for its too heavily restrictive attitude.

Will New York Engineers Fail in Their Civic Duty?

AS THIS issue goes to press there is grave danger of the engineers of New York City failing in their civic duty. Elsewhere in these columns are the details of the sudden discharge of 300 engineers of the Public Service Commission, resulting in the disruption of an excellent engineering organization and in a probable heavy loss, through delayed work, to the city. The situation calls for immediate and organized protest by engineers. The work being chiefly of a civil engineering nature and of a public character, responsibility for calling a meeting lies either with the organized body of civil engineers or with an organization designed to handle public questions of an engineering nature. There being no local society of civil engineers in New York, responsibility lies between the American Society of Civil Engineers and the Engineering Council. The society, holding that it had passed its civic functions to the Engineering Council, promptly, by telephone message of its secretary, urged the council to take the matter in hand. Up to this writing (Tuesday, noon), the executive committee of the council has refused to call the much-needed meeting of protest.

The reason has not been made public, but the weakness of the committee's position is shown by the known fact that it is ready to take action if it receives a *formal communication* from the Public Service Commission or from one of the Founder societies requesting action. *Formal communication!* when the story of the injustice and the disruption is spread in every newspaper in New York City, when an Associate of the American Society of Civil Engineers has spread the matter before the council in a letter, when the secretary of the same society has urged the council by word of mouth to act, when other engineers who know the situation thoroughly have orally put the matter before the council's executive committee. *Formal communication!* while meanwhile every engineer in New York City with red blood in his veins is boiling at the injustice to his fellows and the loss to the city. But the end is not yet. Before the week is out, we hope, the executive committee of the council will have acted, and the engineers of New York will have registered a ringing protest. Meanwhile, this weakness of engineering society organization in New York City needs to be recorded, this inability of the engineers to secure quick action in the discharge of their civic responsibilities. The Engineering Council will have its side to tell, but this fact is outstanding, that it has delayed action awaiting a *formal communication* on a pressing matter on which even the man in the street is informed.

Theodore Roosevelt and the Engineer

THIS is not the place for any extended comment on the personality or work of Theodore Roosevelt. For two of his activities, though, engineers have especial reason for remembering and honoring him—his vigorous backing of the Panama Canal work and the impetus he gave to the movement to conserve our natural resources. In both he displayed a keen appreciation of technical features and backed the engineers with a vigor that could be the result only of strong faith in men of professional training.

His interest in the Panama work, particularly, was of value to the nation. The project had dragged along in the report stage for years. With his accustomed desire for action, he put the job under way, first taking what was then the very sensational step of casting aside the majority report of the international commission, which favored a sea-level canal, and accepting the minority's view. We know now, as a result of the building of the canal, that he was well advised in his choice. What part he played, whether of action or acquiescence, in the Panaman revolution, the first step in the realization of the canal project, is not for discussion here.

In the conservation movement his ability to grasp problems was no less clearly shown, and with the emphasis that he so well knew how to put on things that he wanted cast into the public eye, he made conservation the most talked-of subject in the country in a few weeks' time. What the result of his work in this direction has been has not, so far as we know, been appraised. That it gave a new impetus to the engineers' work in trying to conserve our resources there is no doubt. The full vigor of the early propaganda seemingly is lost, but there is good reason to believe that much of it has been translated into effective machinery for investigation, administration and operation.

In respect to one of his activities the engineers of the future will have more cause than those of the present to remember Colonel Roosevelt. The social-justice program of his 1912 campaign was about six years ahead of the time. Belittled then and scoffed at, it has now been accepted by employers, in theory at least. There was clear evidence of that at the recent Atlantic City Reconstruction Conference. In the coming day those instrumentalities of industrial coöperation will be placed on a scientific, on an engineering, basis, and then some engineers will revert to the 1912 campaign and marvel at the foresight of Colonel Roosevelt and at the denseness of American business.

Administrative Ability in Technical Work

IN THE readjustment for peace conditions which is now just beginning, one of the serious mistakes made in the readjustment for war conditions, which was carried out in 1917, should be avoided. When the nation's resources were being mobilized, eighteen months ago, there was a great demand for engineers to fill places in the little rectangular spaces of numberless so-called organization charts. The harassed higher officials, with their utterly inadequate staffs, trained in precedents and fettered by red tape, had to create proper organizations while carrying on business with what they had. The Construction Division of the Army grew out of an unimportant section of the Quartermaster Corps into a most effective agency because it had the benefit from the outset of the advice of some of the most successful engineers and builders in the country. In the same way the Bureau of Mines, with the help of successful specialists, organized the Chemical Warfare Section, the most imposing aggregation of chemical technologists the country has seen. But there are other departments whose success has been less marked, which

brought into their organizations a large number of technical men of good reputation, but which nevertheless failed to make much progress. These conditions have caused much comment, and the general explanation of them, made by men who have been successful in private life and successful in Government work during the war, is full of warning to those who are taking up the readjustment to meet the requirements of peace.

Where a war-time agency has been successful, it has had an organization in which the difference between technical knowledge and administrative ability has been recognized in the appointments and the scheme of management. In a general way, everybody recognizes this difference, but practically few men, not themselves experienced executives, appreciate its importance. Bureau chiefs in Washington, whose salary lists were so low they could not obtain men of both technical and administrative ability in competition with private corporations, failed to realize that such men would be willing to serve the public in war times at Government rates of compensation. The new men they brought together often lacked administrative capacity, and needed so much overhead direction and control that progress was slow, in spite of the abundance of technical talent that was gathered together.

This is not the place to enter into a prolonged discussion of the administration of technical undertakings. It is enough to say that the war has proved beyond question that, while there is an abundance of technical talent in the country, the combination of technical and administrative talent necessary to make speed economically in war times is the same combination necessary to make profits in peace times, and it is far from plenty. It is the result of an astigmatic view of the duties of the average technical executive, which lays stress on his scientific knowledge and blurs the importance of his ability to plan and direct the work of others. Administrative capacity has a higher value than technical knowledge in many presumably technical positions, and as it is more difficult to obtain it should be examined into more carefully. The technical schools should also recognize this fact, and turn out graduates who know that the ability to direct others successfully has a big cash value, even in a scientist.

Political Piracy With the Engineer as Victim

POLITICAL piracy has many discreditable deeds in its book, but most of these are outdone by the action of New York City's governing body, the Board of Estimate and Apportionment, in tearing to pieces the Public Service Commission's engineering department on the eve of the new year. Certain consequences of this action, perfectly obvious and as well known to the board as to any citizen, have an ugly appearance. But because a great enterprise of engineering construction is involved, and a great engineering organization performing urgently necessary functions is made the immediate victim of the vicious act, the occurrence becomes one of peculiar concern to engineers.

By vote of the board in connection with a running-expense appropriation, the commission was ordered to dismiss a third of its staff. More than 300 engineers were thrown out on a few hours' notice, without apology or farewell. These men were and are badly needed, on rush work now under construction and on other work soon to be let. So far the bare facts—except perhaps the brief note that, as every one in the street knows, the board has for some time been engaged in bitter personalities with the commission as a whole and with individual members.

Now for the background, of justification or accusation. A score of subway and elevated railway contracts are under way. Some of them were being urged along as fast as possible, as closing links in lines shortly to be put in operation. Many other contracts for finishing work and equipment are also under way. Additional work was being prepared for contract, and this, besides its local importance in helping to bring the city's sadly deficient transit facilities up to requirements, would have been of national influence in aiding to restore the normal course of industrial life in the nation, momentarily checked and reluctant.

All of this activity under the Public Service Commission's jurisdiction is vitally dependent for its progress on the engineering department. A highly expert organization—now wantonly dismembered—had been built up in the course of years to perform this essential municipal service.

By contract stipulation, all engineering data, all lines and grades, all directions and instructions as to quality and quantity, all estimates for payment, must be supplied by the engineers. In much of the work the constant day-and-night attendance of engineering parties is required, aside from inspection. Without this engineering service, the contractors cannot proceed; their work will be delayed, their plant and organization expense continuing, and the city, in the end, must pay the bill. Delay in subway service means further cost—a week's interest on the idle investment already made will weigh up the three-month "saving" in salaries which the board accomplished.

It was known to the Board of Estimate, which itself passed upon the contracts, that the construction work cannot go along without the engineers. It was known to the board that New York needs the service of the new lines, and is paying tens of thousands of dollars daily in interest on idle investment. It was the board's plain duty to know that losses of great amount would fall upon the city if it delayed the work. Did the board, then, act in ignorance? Or must we entertain the hypothesis that it acted with deliberate malice?

So far as engineers are citizens merely, their interest lies in fighting the wrong done the community, and in coöperating with the rest of the community in answering the challenge of the recreant officials by the law and by the ballot. As technical men, however, they have a somewhat specialized duty.

It is their privilege as well as their duty to brand with proper opprobrium the baseness that uses a great engineering work as the plaything of personal antagonisms. It is theirs to write on the record a proper characterization of the outlawry that destroys a trained engineering organization, a municipal asset. And, we think, it will be their privilege to take this occasion for protesting against the subordination of intricate technical problems, and of men trained in their solution. to the whims of political chancemen.

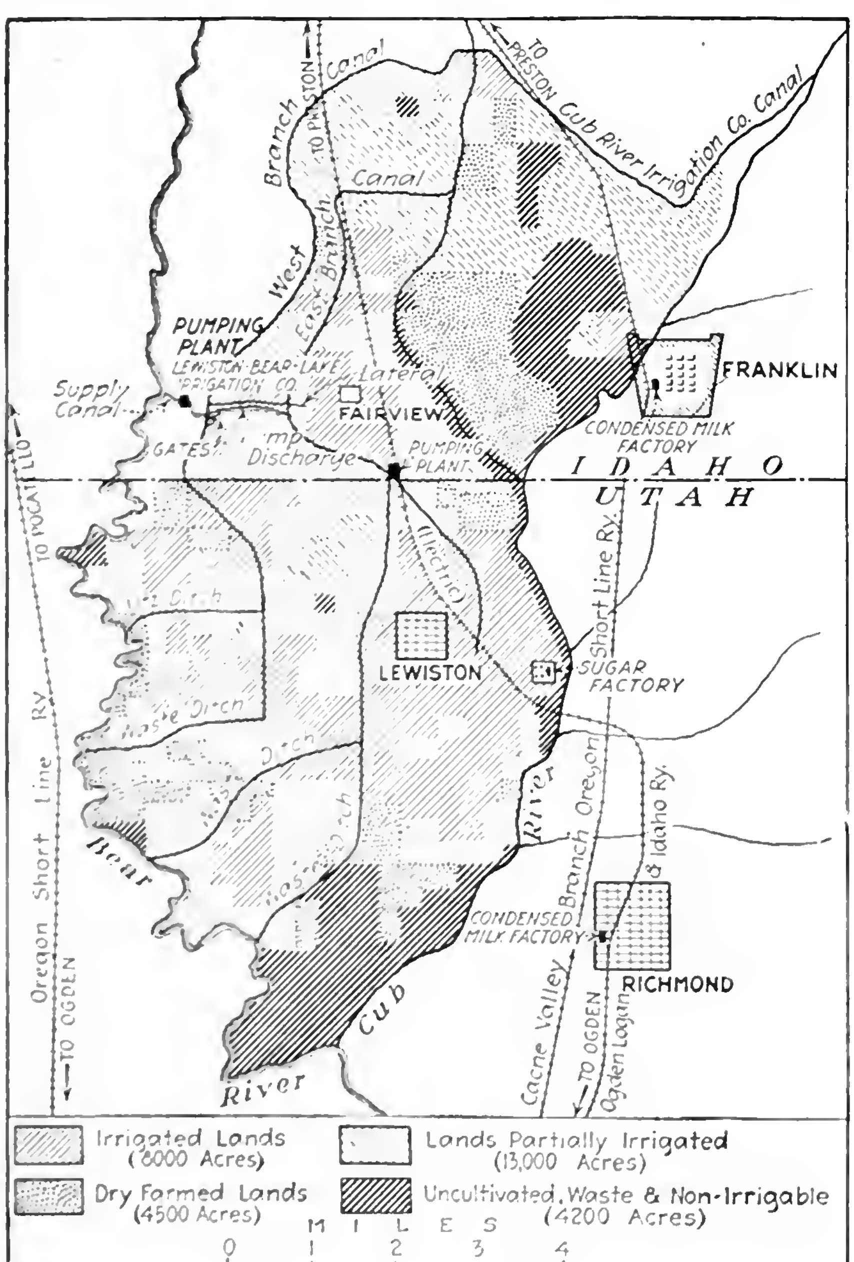
Electrically Driven High-Lift Centrifugal Pumps Supply Water for Irrigation

Water Forced Through Steel Manifold to Reinforced Concrete Conduit Leading Up to Canal—Design Features—Pump Tests Show Over 81 Per Cent. Efficiency Under 90-Foot Head—Construction Work

By B. P. Fleming
Mechanical Engineer, Member American Society of Civil Engineers, Iowa City, Iowa

EVERY year sees greater strides made in irrigation by pumping. This article describes a new high-lift irrigation pumping project with steel manifold and reinforced-concreted force main, put in successful operation in 1917 for supplementing the water-supply of a large area known as the "Lewiston Flat" in northern Utah and southern Idaho. This district is one of the most progressive and productive agricultural districts of the inter-mountain region, the products being sugar beets, dairy products, alfalfa, grains and potatoes. Two sugar-beet factories and two condensed-milk factories are located in the district, and the farming generally is on an intensive and profitable basis where and when water for irrigation is obtainable. Power at low cost as well as intensive agriculture make high-lift pumping feasible.

The irrigable area of the district has been estimated at about 30,000 acres, of which about 20,000 are under existing canals. For the past 40 years the water-supply has been derived from a small stream known as the Cub River, a tributary of the Bear River. The flow of the Cub varies from about 400 sec.-ft. in June to an amount not exceeding 60 sec.-ft. in July and August, during which months the valuable sugar-beet crop is most in need of water. In normal years about 8000 acres of the Lewiston district would be fairly well supplied with water over the entire season, 8000 acres would receive only sufficient to grow grain crops or mature one crop of hay, while 4000 acres might receive no water at all.



CLASSIFIED DISTRIBUTION OF LANDS IN LEWISTON FLAT IRRIGATION PROJECT, IDAHO, UTAH

The securing of such a supply of water as might permit not only of adequate irrigation of the area now farmed but also would lead to a development of the entire irrigable area, has been a very important public question in the district for many years. Various surveys both by Government and private agencies have shown the economic impractability of development of additional water-supply either by gravity flow from the Bear River or by storage developments on the Cub River, so that pumping from the Bear River seemed to be the only solution of the problem.

The Bear River lies from 85 to 90 ft. below the general level of the lands in question. Its natural flow has been entirely appropriated by agricultural and other interests along its course in Idaho and Utah, so that the only hope of the district was in securing a right to stored water. This, fortunately, was obtainable through the extensive storage developments begun by the Telluride Power Co. and completed by its successor, the Utah Power & Light Co., on the body of water known as Bear Lake, in northern Utah. This development comprised the construction of a large pumping plant of 1500 sec.-ft. capacity and control gates which, together with an artificial channel between Bear Lake and the Bear River, make it possible to divert floods into the lake and store them there, or, in case of long-continued drought, permits the pumping out of the waters of the lake to a depth of 17 ft. below the normal stage, and thereby augmenting the flow of the river.

The object of this development is to insure continuity of operation of the large hydraulic power plants established on Bear River, but, incidentally, it has assisted to a certain extent in the possibility of agricultural development, by providing some stored water for the use of those who are able to secure a right to it, and who can divert it below the power plants. The attractive rates for electrical power for pumping offered by the power company, together with the offer of a right to a certain amount of stored water, led to the inception of the project here described. The amount of water estimated as necessary to be supplied by pumping, to supplement gravity water, was 10,000 acre-ft. Since

this amount must be supplied mainly within a period of 50 days, the capacity of the plant became fixed at 100 sec.-ft. For flexibility in operation, it was decided arbitrarily to build a plant of four units of 25 sec.-ft. capacity each.

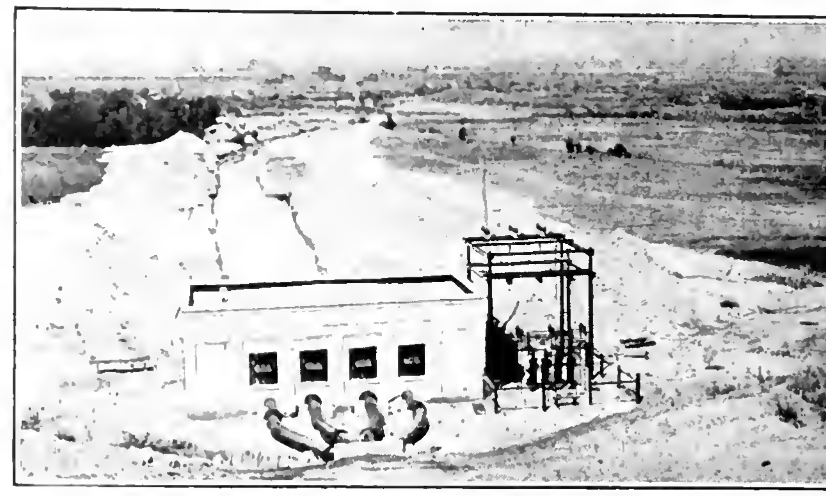
The plant was located directly west of Fairview, Idaho, at which point the Bear River approaches quite near to the present canal system of the Cub River Irrigation Co., into which the pumped water was to be discharged.

The site finally selected for the plant was on a hillside and flat adjacent to a V-shaped bend in the Bear River. Preliminary studies were made of the comparative cost and general suitability of a plant located at the river and discharging into a canal at the crest of the hill through a long wood-stave force main, and a plant located at the base of the hill and taking water from a supply canal leading to the river and discharging through a comparatively short concrete or steel pipe into the canal. Test pits dug on the line of the pump supply canal and at the proposed site of the pump-house structure seemed to indicate that although water would be encountered in large quantities, the necessary excavation required by the second plan could be carried on without serious difficulty. How far this surmise missed the true conditions is related under "Construction." The comparative studies made indicated that the second plan was the more feasible and economical, particularly since it was the desire to eliminate entirely the use of wood-stave pipe, which under the conditions of a pumping plant in use only a few months of the year, cannot be properly maintained. The distance through which the water would have to be carried under pressure, in the case of a plant located at the river, and the size required, seemed to indicate that only a wood-stave pipe could be considered from the standpoint of initial cost—and this fact was of the greatest weight in the decision to adopt the other type of plant.

Another factor having an important bearing upon the general design of the pumping station was the type of pump to be selected, whether vertical or horizontal. This matter was not decided until after bids had been received upon both types. It is significant of the favor with which these two types of units are regarded by the pump manufacturers themselves that, out of seven manufacturers represented, only one would offer a bid upon the vertical unit, and the others were most decidedly opposed to its use under the circumstances.

After various studies had been made, it was found that a concrete pipe was practically as cheap as a riveted steel pipe of the same internal diameter, so concrete was decided upon because of its greater permanency and lower friction loss, as well as the less difficulty in securing construction materials. The design of a reinforced-concrete manifold to receive the discharge from the four pumps proved to be so difficult that it was abandoned in favor of a riveted steel manifold. The full-discharge velocity throughout the manifold and the concrete pipe was limited to 5 ft. per second, and in the design of the manifold an attempt was made to give the easiest flow lines possible while yet maintaining a form providing a maximum of strength. The manifold has a circular section in every part, and in order to insure additional stiffness a vertical plate is riveted in the crotch of the breech-like portion. No leak of consequence was discovered in any of this riveted steel construction.

Some concern was felt by the designers as to the probable pressure effect in the steel manifold and the concrete discharge pipe resulting from sudden closing of the hydraulic gate valves on the discharge side of the pumps. If, for any reason, power goes off while the pumps are in operation, the pumps almost immediately begin to run backward, and the water in the discharge pipe attains a fairly high velocity backward down the pipe. Checking this flow suddenly by the closure of the gate valve would cause water hammer. Calculations, based upon the various formulas tried, while not giving consistent results, seemed to indicate that no dangerous pressures would be developed. A small relief valve was, however, placed at the end of the steel breeching. In the operation of the plant and in the deliberate creation of conditions favorable for water hammer at the time of testing, scarcely appreciable rises in pressure were noted.



WATER FROM RIVER IS PUMPED THROUGH STEEL MANIFOLD AND REINFOCED-CONCRETE CONDUIT

A vacuum relief valve was also placed at the top of the concrete pipe at Sta. 14 + 17, at which point there is a break in vertical alignment where vacuum conditions may be created by the rapid letting out of water from the pipe. The free area of the air valve is about 1% of the area of the pressure pipe.

Excessive temperature changes in the concrete and steel piping were anticipated, since, although backfilling over the concrete pipe was proposed, it was not of sufficient thickness to insure against considerable daily and seasonal temperature changes, while the steel piping was completely exposed. Expansion joints in the concrete pipe were considered, but the difficulty of construction and the possibility of leakage led to the rejection of expansion joints altogether in the concrete pipe and the placing of dependence upon the longitudinal reinforcement alone to prevent the formation of transverse cracks. It was planned also to construct the pipe in cold weather, and this was successfully accomplished by late spring, before hot weather had set in. No leaks of any magnitude have so far (April, 1918) appeared in the pipe although water was turned into it for the first time early in July, 1917, when there was probably 50° difference in temperature between the pipe and the water. Expansion joints were introduced in the steel piping of the manifold next to the pump-house, and the pump side of the joint was anchored securely to piers braced against the pump-house foundation.

The substructure of the pump-house is of reinforced concrete, designed to withstand a water pressure of 15 ft. The sump floors are designed to act as beams between the sump walls. The parts of the floor beneath the machinery were designed as beams heavily reinforced. Elsewhere the floor is 6 in. thick, well reinforced. The walls are 15 in. thick. The superstructure walls are of brick. They sustain a concrete crane girder, a 10-ton crane, and a flat roof supported by 12-in. I-beams. The roof is 3 to 5 in. of concrete on asbestos-steel corrugated roofing, and is covered with tar felt and gravel. The crane is provided with hand-operated lifting and racking mechanism.

Sump Drainage—Hydraulic Gates—Pumps

To drain the sump beneath each main pump unit, there is a 3-in. motor-driven side-suction centrifugal pump, with a valve-controlled 4-in. suction pipe. For priming the main pumps and the sump pump, a motor-driven rotary vacuum pump is provided, its suction being connected to a vacuum main from which branches lead to each pump. To the priming pump, immediately above each main unit, is attached a gage glass by which the operator can tell exactly when the unit is primed. Some difficulty was met in the initial operation of the priming pump, due to inexperience in adjusting the amount of water needed for water-sealing it. When finally adjusted, it would prime a main unit in from 5 to 7 minutes.

The hydraulic gate valves are 18 in. in size and are provided with a hand operating device for use when the pumps are first started and no pressure head is available in the discharge line for their operation. This device was found by no means satisfactory, since its design requires an entire dismounting before the valves can be operated hydraulically. The control of the hydraulic valves is centralized at a point near the switchboard, so that after priming a unit and starting the motor the operator merely turns a small pilot valve which opens the main valve. A reverse motion of the pilot valve likewise closes the main valve, so that the operation is very easy and rapid. Hydraulically rather than electrically operated valves were chosen because of their greater simplicity and much smaller first cost. Their operation in this plant has been eminently satisfactory.

Each main pump unit is an 18-in. double-suction split-case centrifugal pump with bottom horizontal discharge and vertical suction connection. The impellers are of bronze, and a bronze sleeve covers the shaft from the impeller out through the stuffing-boxes. The latter are water-sealed and were provided with bronze lantern rings.

Water for sealing was taken originally from the pumps themselves, which necessitated tightening the glands when priming. It is now proposed to utilize clear water from a spring near the station which will give sufficient water under pressure for water seal irrespective of the operation of the pumps.

The pumps are provided with ring oiling bearings in split babbitt cases. A flexible coupling attaches the pump to a 350-hp. induction motor on the same bedplate. These motors are three-phase, 60-cycle, of the squirrel-cage type, using current at 440 volts. Each motor is controlled from its own switchboard panel, the cable running in a conduit laid in the floor.

The switchboard is of standard slate construction and consists of six panels. Of these, four are motor panels, on each of which is mounted an ammeter, an integrating watt-hour meter, and the triple-pole single-throw oil switches. One panel is a totalizing panel, on which is mounted a totalizing wattmeter, a totalizing integrating watt-hour meter and a graphic recording frequency meter. On the sixth panel are a volt meter and the instruments of the auxiliaries and lighting circuits, comprising a watt-hour meter and the necessary single-throw switches for the house lights and auxiliary motors.

The current is transmitted to this station from the Preston substation, about six miles away, at 44,000 volts. Current is transformed into the 440 volts used at the plant by a bank of three 500-kva. transformers of the outdoor, oil-filled, air-cooled type. Four 44-kv. aluminum cell lightning arresters are provided for protection against line surges and lightning discharges, and the other equipment includes disconnecting and line switches, choke coils, expulsion fuses, etc. Serious difficulty experienced in times of electrical storms with high potential discharges on the secondary side, soon after operation was started, led to the installation of secondary arresters between the transformers and the switchboard, in addition to the more thorough grounding and transformer cases.

Tests

The contract between the pumping enterprise, or the Lewiston-Bear Lake Irrigation Co., and the Utah Power & Light Co., comprises many features intended to penalize peak-load conditions and to encourage an endeavor to economize on power consumption, although the base rate is only 1c. per kilowatt-hour. In the design of the plant, therefore, an effort was made to eliminate so far as possible hydraulic energy losses in piping and sumps, and in preparing the specifications an efficiency for the pumping units themselves of 81% was demanded. This figure was considered a not unattainable ideal, but one of the largest pump manufacturers in the country refused to bid upon the basis of this figure, and several other manufacturers were very loath at first to offer to attain this efficiency, particularly since the contract was so worded that a certain percentage of the contract price was to be withheld pending the attainment of the guaranteed efficiency. Inasmuch as this percentage amounted to $12,000, the contract provided for very complete tests of the pumps upon completion of the plant. Considerable thought was given to the matter of accurate water measurement. After rejection of other methods because of difficulty of operation or probable inaccuracies, it was decided to install a 14-ft. Cippoletti weir in the discharge canal, 200 ft. below the outlet of the discharge pipe and at the end of the concrete-lined section of the canal. The weir was constructed of 2-in. grooved and tenoned lumber with a thin steel plate for the weir crest, the weir being installed in a substantial concrete structure, with provision for removing the weir board upon completion of the tests. Heads on the weir were measured by a hook gage reading to thousandths of a foot, the zero of which was de-

termined by an engineer's level. Bazin's formula, as tabulated in Williams' and Hazen's tables, was used for calculating weir discharge. Although Bazin's formula is based upon the use of a weir without lateral contractions, it is recognized that the trapezoidal weir with side slopes of 1 to 4 gives a discharge "equal to that of the rectangular weir without end contractions"; hence Bazin's formula may be applied to the determination of the discharge of the weir in question and provides a very convenient method of computation, inasmuch as velocity of approach is taken into account in the formula and may be neglected when the weir conditions are comparable to those of Bazin, which it was the endeavor to secure in this case.

Pressure head on the pumps was determined by a calibrated Bourdon gage and suction head by a mercury manometer, both being referred to the axis of rotation of the pumps as a datum. Power input to the motors was measured at the motor terminals by an indicating polyphase wattmeter, current transformers only being used. Merely as a check, the readings of the switchboard instruments were taken during the test, but were not used in making calculations. Subsequent to the test the gages and electrical instruments were calibrated, and these calibrations were used in making the official calculations. In calculations of pump efficiency the motor efficiency was assumed as that shown by factory test at full load, 91 per cent.

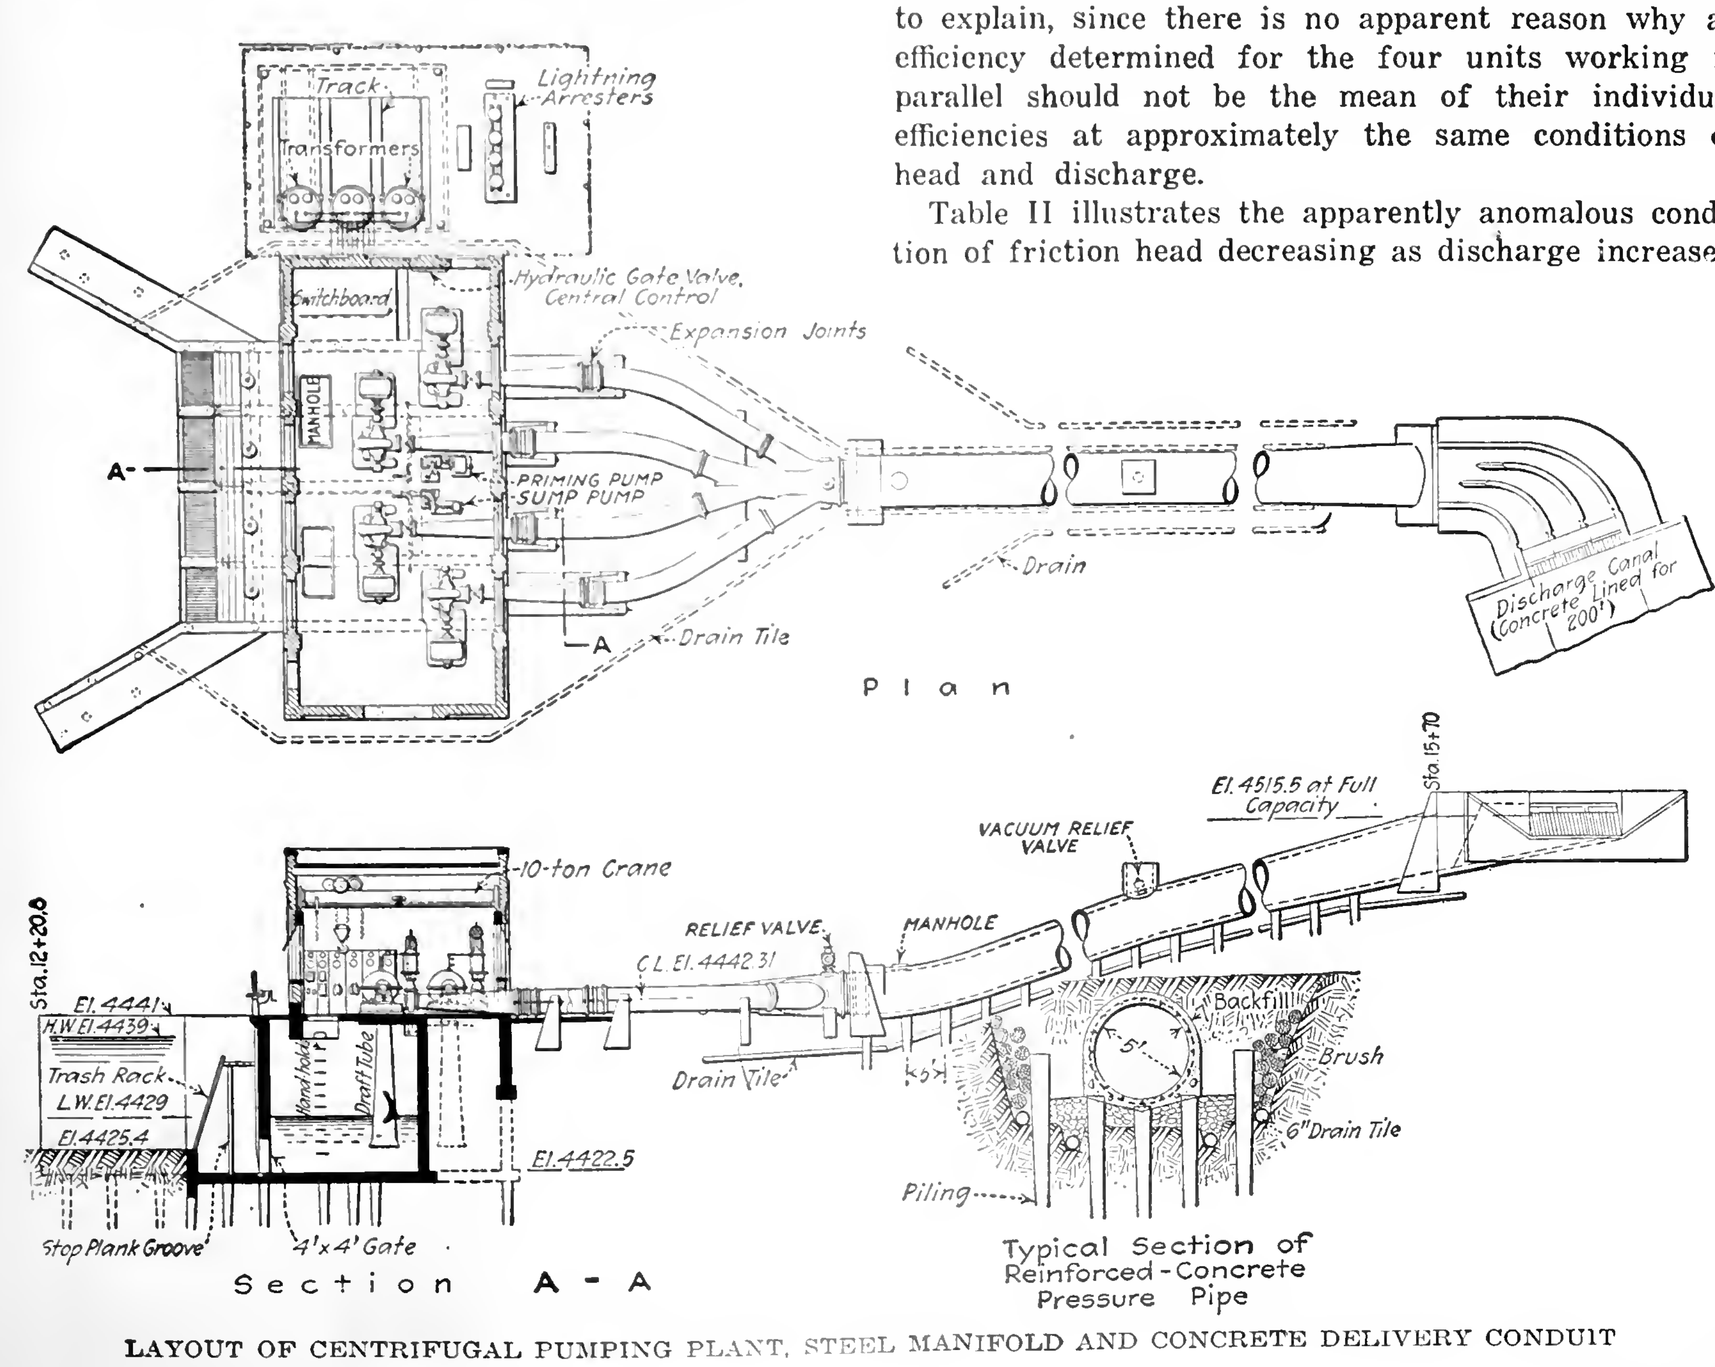
In testing (see Table I), the pumps were each run separately at three heads, the heads being varied by partly closing the hydraulic gate valves. Following the runs of the individual pumps all four were operated together to determine the action of the manifold as regards friction effect.

TABLE I. RESULTS OF CENTRIFUGAL IRRIGATION PUMP TESTS

Unit No.	Discharge Head, Ft.	Suction Head, Ft.	Total Head, Ft.	Static Lift, Ft.	Discharge, Sec. Ft.	Water, H.P.	H.P. Input	Pump Efficiency %	Speed
1	70.1	18.2	88.3	85.35	28.36	284.5	344.6	82.5	886
1	75.8	17.7	93.5	85.26	27.51	292.0	347.6	84.0	883
1	81.5	16.75	98.25	85.05	25.95	290.0	344.4	84.2	889
2	70.1	18.1	88.2	85.34	27.69	277.5	344.4	80.6	880
2	75.3	17.5	92.8	85.20	26.82	282.8	347.8	81.3	880
2	80.5	16.9	97.4	84.90	25.76	285.0	350.0	81.4	882
3	70.1	18.3	88.4	85.23	28.52	286.2	341.6	83.8	...
3	74.8	18.1	92.9	85.24	27.81	293.6	344.6	85.2	...
3	81.0	17.4	98.4	85.38	26.09	291.9	341.6	85.4	...
4	69.9	18.6	88.5	85.55	27.72	278.3	339.6	81.9	884
4	74.8	17.9	92.7	84.91	27.22	286.3	343.5	83.4	882
4	80.3	17.2	97.5	87.79	26.32	291.4	344.0	84.7	880
1, 2, 3, 4	71.1	17.4	88.5	85.8	108.01	1086.0	1421.5	76.5	

The most significant figures in Table I are those on pump efficiency. It will be noted that efficiencies of over 85% were attained by No. 3 unit, while all units are safely over the guaranteed efficiency of 81% at 90-ft. head. The lower efficiency of No. 2 unit is thought to be due to a small air leak in the suction pipe. This leak was not discovered until the tests had been completed. With all the pumps in operation there is noted a distinct falling off in pump efficiency which is difficult to explain, since there is no apparent reason why an efficiency determined for the four units working in parallel should not be the mean of their individual efficiencies at approximately the same conditions of head and discharge.

Table II illustrates the apparently anomalous condition of friction head decreasing as discharge increases.



LAYOUT OF CENTRIFUGAL PUMPING PLANT, STEEL MANIFOLD AND CONCRETE DELIVERY CONDUIT

This is probably due entirely to the better flow conditions established in the steel manifold when all four branches are discharging than when one only is being used, so that the saving of head here more than overbalances the greater loss in the concrete pipe due to the increase of velocity when carrying 108 second-feet.

TABLE II— FRICTION LOSSES BETWEEN DISCHARGE CANAL AND FOREBAY

Unit No.	1	2	3	4	Four in Parallel
Total static lift, ft.....	85.35	85.34	85.23	85.55	85.8
Discharge head, ft.....	70.1	70.1	70.1	69.9	71.1
Suction head, ft	18.2	18.1	18.3	18.6	17.4
Total head, ft.....	88.3	88.2	88.4	88.5	88.5
Friction head, ft	2.95	2.86	3.17	2.95	2.7
Discharge, sec.-ft.....	28.35	27.69	28.52	27.72	108.01

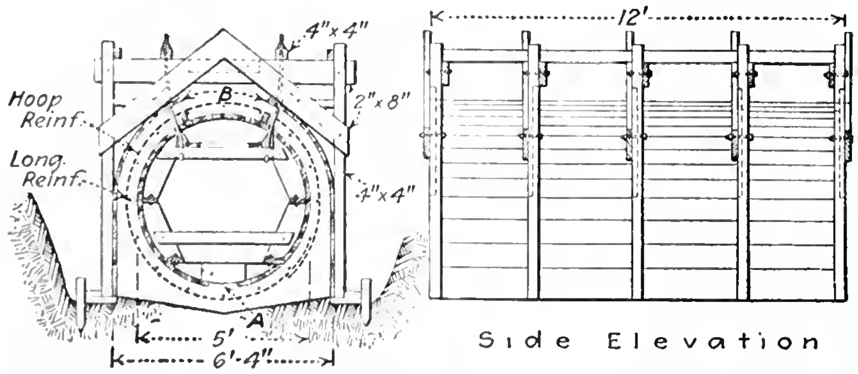
As a whole, the efficiency tests of this plant illustrate the recent very remarkable advance in centrifugal-pump design from the standpoint of efficiency, and give reason to believe that it is not too much to expect that in the case of large units, working under reasonably high heads, 85% efficiency may be obtained where the character of the installation is such as to warrant the extra expense of a pump designed for the special conditions under which it is to operate. It is to be noted that such efficiency can only be obtained by the use of small running clearances in the impeller at the wearing ring which prevent leakage from the discharge back to suction; and the water seal preventing air leakage into the suction passage around the shaft must be perfectly air-tight. Wear is to be expected in the course of time in the wearing rings, and the glands cannot be maintained in perfect condition after a long period of use, so that to maintain the high efficiency found when the installation is new it will be necessary to renew from time to time the wearing rings and the bronze sleeves on the shaft.

Construction

Active construction work was begun in September, 1916. To J. E. Wilson, Jr., of Logan, Utah, was awarded the contract for the pump-house building and foundations, the supply canal and all concrete structures, including the concrete pipe and the outlet, the weir and the various structures in the discharge canal.

The contractor's scheme of operation was to use a dragline excavator for the supply canal and for as much of the pump-house excavation as could be reached by such a machine. The excavation for the concrete pipe was attempted by teams and slip scrapers. The work had progressed only a short time when great and increasing difficulty was experienced with slides and cave-ins. The whole hillside was found to be in a completely saturated condition, and the site of the pump house and most of the supply canal was found to be underlaid to a great extent by an undetermined depth of quicksand. No progress could be made with the pipe trench until several lines of drain tile and brush drains had been put in and piling had been driven 5 ft. c. to c. almost the entire length of the pipe. Although the use of piling under either the pump house or the pipe had not been contemplated, the uncovering of the subsoil conditions made it necessary to use about 400 piles beneath the force main. Cave-ins in the pump-house excavation delayed the work greatly and increased enormously the amount of material to be moved. When the point was reached where concreting could be done it was midwinter. Most of the concrete in the foundation was placed when the thermometer never rose above freezing temperature. Forms frequently were overthrown or misplaced by cave-ins before concrete could be poured, and the water rose so rapidly in the excavation that a 3-in. centrifugal pump was kept going night and day. Nevertheless, in the face of such discouragements, the foundations were built and the superstructure was erected in time for the completion of the plant before the irrigation season of 1917 started. The pump-supply canal likewise involved serious difficulties in excavation, and it was found necessary to use side slopes as flat as 2½ to 1 to prevent slipping. This required the removal of excessive quantities of material and repeated dredging of the bottom, in order to establish a grade.

The construction of the concrete pipe involved form work of so interesting a character that it will be detailed. The hoop reinforcement was formed first to circular shape of the proper diameter, the ends being lapped about 18 in. and securely wired. It was then assembled in place and spaced by being wired to the longitudinal reinforcement. The inside form was then assembled inside of the reinforcement. The inside form was made in 12-ft. lengths, in six sections, five of which were bolted together at brackets. The sixth or top section rested on wedges supported on a cross-brace, and the whole inside form was hung by ½-in. rods, hooked on each end and attached to eye-bolts, passing up through 4 x 4-in. longitudinal stringers supported by the outside form framework. Thus the inside form could be raised or lowered into exact position by the adjusting nuts on these eye-bolts, the outside form first having been set to correct position and grade. The hoop reinforcement was supported in proper position by small blocks resting on the inside form. It will be noted that the bottom of the inside form was left open



FORMS FOR 5-FOOT CONCRETE DELIVERY CONDUIT

at A (see detail), and that an opening, B, was left in the outside form. The latter was held together by ½-in. bolts, to facilitate disassembling and moving.

Concrete was poured through a spout into opening B from a trough running the length of the pipe and supplied by a mixer established at the crest of the hill. The opening A gave an opportunity to see that the concrete was worked well underneath the inside form and completely filled the bottom of the pipe. After concrete had been poured partly up the sides of the pipe, the hooks supporting the inside form were removed and pieces of tin were tacked over the opening; the blocks supporting the reinforcement also were removed, so noth-

ing was left in the concrete to prevent the pipe from being perfectly tight, and no patching of the hole was necessary. Forty-eight feet of pipe was poured every alternate day. Care had to be exercised not to use too wet a mixture, as at the start some difficulty was experienced with the concrete running up through the bottom opening in the inside form.

The morning following the pouring of the concrete the first 12 ft. of inside section was taken to pieces and moved ahead through the other sections and reassembled. The other sections followed, until all were moved ahead and set ready for the pouring of the concrete the following day.

The conduit as finally completed was an exceptionally neat and smooth job inside, and when plastered with neat cement a surface was insured which, as subsequent tests showed, gave little frictional resistance to the flow of water. No leaks of any consequece developed in the entire length of the pipe—a mere sweating, which soon stopped completely, being noted soon after water was turned in near the lower end.

The joint at the junction of the concrete pipe and the manifold is worthy of notice. It is a section of steel pipe 5 ft. in diameter. A length of 3 ft. is bedded in the concrete block at the lower end of the concrete pipe, there being two 3-in. angles riveted around the steel pipe to act as cut-offs. The longitudinal reinforcement was passed through holes drilled in the flange of one of these angles and bent back to form a loop, thus being held securely to the reinforcement of the concrete pipe. No packing joint around the steel pipe between it and the concrete was provided, and no leak of any consequence has yet been noted at this point.

Design of Outlet—Contract Costs

The outlet at the upper end of the concrete pipe presented in construction some difficulties that were overcome. The curved interior walls are for the purpose of directing the flow of water as it issues from the enlarged end of the pipe so that it does not bank up against the outside wall.

To insure a minimum of leakage between the outlet and the measuring weir at the time of testing, the outlet canal for 200 ft. was lined with concrete. This has a thickness of 4 in., the bottom width being 12 ft. and the side slopes 1½ to 1 to a water depth of 4 ft. The concrete was laid in alternate sections about 12 ft. in length, and no special provision was made for joints.

The contract cost of the various items was as follows:

Supply canal, 23,485 cubic yards	$8,220
Pump house and foundations	13,534
Reinforced-concrete pipe and outlet	5,007
Delivery canal, 23,000 cubic yards	3,450
Light structures on delivery canal	3,461
All machinery and equipment, including erection	40,000
Total	$73,672

No extras of any consequence were found necessary on any but the first three items. The very difficult excavation for the pump-house foundations, concrete pipe and supply canal, and the greatly increased amount of material which had to be moved, due to slides and cave-ins, as well as the necessity of using piling under the pump house and pipe, increased the cost very materially. The final cost, therefore, of the completed project, including right-of-way, engineering and legal expenses, was $96,000.

The machinery and all the hydraulic and electrical equipment was furnished by the Allis-Chalmers Manufacturing Co., Milwaukee, Wis., through the Salt Lake Hardware Co., contractor. The erection of machinery was subcontracted to the Lynch Construction Co., Ogden, Utah. The concrete structures, including the pump house and the supply canal, were contracted by J. E. Wilson, Jr., Logan, Utah. The supervision of the work was under the immediate charge of T. H. Humphreys, hydraulic engineer, Logan, Utah, and most of the detailed plans and drawings were prepared by the writer.

Mixer Association Standardizes Mixer Rating

Wet-Batch Capacity Is Taken as Basis After Careful Study of All Factors and Submission of Questionnaire

By G. B. Arthur
Manager, Concrete Mixer Association

It is not necessary in this day to argue the advantages of standardization to anyone engaged, as engineer or contractor, in engineering work. For example, the field would be thrown into utter confusion if an electric motor rating meant one thing to one manufacturer and another to someone else. Intelligent design, intelligent purchasing, intelligent operation are not possible so long as the producers of equipment fail to agree on standard methods of designating their product.

What is true of electric motors or steam engines is equally true of concrete mixers. The output of the mixer usually controls the speed of the job. Intelligent "planting" of work, so far as the mixing is concerned, is impossible unless there is a standard rating or the contractor fortifies himself with knowledge of all the fifty-seven varieties of ratings used by as many manufacturers.

Realizing the need and advantages of standardization, the Concrete Mixer Association has adopted a standard method of rating concrete mixers. This is based on the "wet batch"—that is, on the amount of mixed concrete which a mixer will discharge.

Standard Rating Not Absolute

The adoption of a standard method of rating may suggest that such a rating will be absolute, but this is impossible. A No. 7 mixer may mean a mixer which will discharge 7 cu.ft. of mixed concrete of given proportions. But when other proportions are used the output will be the largest batch which is consistent with the use of whole sacks of cement, although when cement is used in bulk the maximum output of the mixer can be obtained with any proportions.

A system of rating can be established only by taking a mixture of given proportions as a basis, with the understanding that this rating can apply only to the proportions specified, and that the output, when other proportions are used, will vary with the size of the batch, which in turn is determined by the method of handling

the cement. And while any rating should be expected to state the capacity of the mixer, this capacity might be either in terms of loose, unmixed material—called "dry rating"—or, according to the "wet rating," in terms of mixed concrete in one batch as discharged from the mixer.

The "wet rating" was adopted by the National Association of Mixer Manufacturers before that organization was dissolved to form the Concrete Mixer Association, and it became so familiar to buyers and users that any change in the method would seem like throwing away a certain amount of capital; at least, the careful work which brought about the adoption of the method could not be disregarded easily.

On the other hand, manufacturers who were not members of the old organization, and therefore were not consulted when the "wet rating" was adopted, were now to be considered, and most of these manufacturers had used the "dry rating." Some of them made chiefly large mixers, the others made only small ones. The former had much in common with the members who had been parties to the earlier standardization; the latter group, who sold many of their mixers to small contractors, farmers and other individuals, had an entirely different problem. A thought-provoking element in their selling is the principle that when a mixer receives a "dry rating" the buyer is impressed with the "bigness" of the machine and feels that the bargain is highly satisfactory, whereas if it receives a "wet rating," making the rated capacity one-third less, this reduction has its effect on the mind of the customer—he thinks he is not getting as much for his money.

Questionnaire Used

The standardization committee carried its investigation far enough to make a convincing recommendation, but action was deferred until a questionnaire was mailed to a representative list of men and organizations who would be likely to have a preference for either the "wet" or the "dry" method. When the replies were tabulated as in Table I it was seen that the preference was in accord with the report which was ready for presentation. It will be seen that of the 283 replies which were made 80% voted in favor of the "wet rating" while 20% favored the "dry rating."

TABLE I. RESULTS OF QUESTIONNAIRE ON "WET" OR "DRY" METHOD

Classification	No. Mailed	Replies Voting "Wet" or "Dry"	"Wet" No.	"Wet" %	"Dry" No.	"Dry" %	Replies Not Voting: Neutral	Replies Not Voting: No Experience	Total Returned	Unclaimed
State highway officials	47	26	19	73	7	27	3	2	31	
Cement companies	82	35	26	74	9	26			35

Engineering societies	26	1		.	1	100	2	1	4	..
Editors of technical journals	6	2	2	100			1		3	
Contractors	505	98	75	76	23	24	7	13	118	43
Other associations	15	11	6	55	5	45			11	.
Total	1,010	283	227	80	56	20	16	19	318	51

One factor probably outweighed all others and became the deciding one, when everything else had been considered: The advisability of using the "dry" method of rating could be disputed in the beginning because the volume of a batch of loose, unmixed materials when thrown together is a variable quantity, depending not only upon the kind but also upon the condition of the aggregates used. A careful reading of the replies which favored the "dry" method gives the impression that in the majority of cases this consideration was overlooked, the writers probably assuming that the volume of a batch of loose materials when thrown into the drum would be so nearly constant as to warrant its use as a basis for rating the mixer. It seems reasonably certain that, seeing that this is not true, many would change their preference to favor the "wet" rating.

As there is only one constant quantity available—the amount of mixed concrete which a mixer will deliver in one batch—the rating is established on this basis, with the following definition: "The standard association method of rating mixers shall be upon the basis of the quantity of mixed concrete which a mixer can deliver in one batch; assuming the use of one part cement, three parts sand and six parts 1½-in. crushed stone; with water at the rate of not more than 1¼ gal. to 1 cu.ft. of mixed concrete; the loose, unmixed batch to be approximated as 1½ times the mixed batch, or the mixed batch as ⅔ of the loose, unmixed batch."

A method of numbering was then adopted which requires that the size of the mixer shall be designated by a number indicating the capacity of the mixer in cubic feet of mixed concrete per batch, based upon the accepted method of rating. The practice of using the letters "S" and "E" to indicate side or end loading is discontinued, because in practice they seem to confuse rather than explain.

With these rules in force a No. 7 mixer can mean only one thing when found in the catalogue of a member of the Concrete Mixer Association—a mixer which will discharge, in one batch, 7 cu.ft. of mixed concrete of the proportions 1 : 3 : 6, using 1½-in. crushed stone, with water at the rate of not more than 1¼ gal. to each cubic foot of mixed concrete. The number 7 thus acquires much significance and becomes the natural beginning for a range of sizes of mixers.

Just before a war conservation program was put into effect in the industry the sizes 2½, 4, 5, 7, 14, 21, and 28 of building mixers were practically adopted for all members. But to conserve as much as possible the War Service Committee revised this, and the sizes 4, 7, 14, 21, and 28 in building mixers were recommended, with the understanding that manufacturers would put into these classes any mixers which were approximately of these sizes. In paving mixers the sizes 10 to 14 were recommended for adoption until it was possible to make the definition more particular. The tendency in the in-

TABLE II. OUTPUT OF CONCRETE MIXERS

Number of one-bag batches which will be discharged by mixers of different sizes, Concrete Mixer Association rating. (No. 10 is for paving mixer only) — Number: 2½	4	7	10	14	21	28	Proportions by Parts: Cement Sacks	Sand Cu. Ft.	Stone Cu. Ft.	Volume in Cubic Feet: Loose Cu. Ft.	Mixed Cu. Ft.
½	1	1½	2½	3½	5½	7½	1	1½	3	5.5	3.7
½	1	1½	2½	3½	5	7	1	2	3	6.0	4.0
½	½	1½	2	3	4½	6	1	2	4	7.0	4.7
½	½	1	2	2½	4	5½	1	2½	4	7.5	5.0
½	½	1	1½	2½	3½	5	1	2	5	8.0	5.3
...	½	1	1½	2	3½	4½	1	2½	5	8.5	5.7
...	½	1	1½	2	3½	4½	1	3	5	9.0	6.0
...	½	1	1½	2	3	4	1	3	6	10.0	6.7

dustries is to hold to sizes recommended by War Service Committees, as far as practicable.

Table II shows the output of these standard sizes for various proportions, and a little study of the variations in one-bag batches will throw all the foregoing statements into sharp relief. It shows also that the standards which have been adopted are practical and rational, and puts them beyond further argument. This table should be made a part of the information supplied for every job, to make sure that the mixer is doing all that should be expected of it; and these standards should not only make it easier to choose a mixer but should also go far toward safeguarding the integrity of the job.

Efforts to Consolidate the Engineering Profession

More Federation and Simplification Which Means Elimination Are Advocated—Problems Which Demand Solution Are Outlined

By A. D. Flinn
Secretary, Engineering Council, New York

THE organization of engineers in America is chaotic, complex and illogical. As consequences there are confusion, waste, inefficiency and dissatisfaction, which, however, are exaggerated in some minds. If no associations existed, it would be relatively easy to plan and create a system of organization that would satisfy demands much more effectively than does the present multiplicity of unrelated societies. But there have grown with the years traditions, and loyalties, and prejudices, clustering about the societies that now are. An answer to the problem thus created is not easy. To me the solution is not obvious, but some progress in the process is now appearing. There must be extensive consolidations, more federation and much simplification, each of which demands elimination. Steps are being taken, or preparations made for them, in various ways and places, and by a number of agencies. They will be accelerated as their benefits gain appreciation; but education, time, and patience are needed for attaining the goal.

The Problems Confronting a Consolidation Scheme

What are the present desirable limits to consolidation and federation? To what goal should they tend? By what methods and means can they best be brought about? These and similar questions are not being answered conclusively, because the necessary facts are not in hand. We have been muddling along in an unengineering fashion, attempting to plan and design and specify without a survey. On Sept. 12, Engineering Foundation by formal vote proposed to make the much-needed survey and preliminary studies, the four Founder Societies concurring. Of the necessity for this survey I have been more deeply convinced with the passing weeks, as I have listened to ineffective arguments and to misstatements based on ignorance which can be corrected only by the results of the proposed survey of engineering organizations.

Without the enlightenment of such a survey it now seems that the following elements of organization are desirable for the engineering profession in America: Excepting possibly three or four cities having large numbers of engineers, there should be in each community, having a sufficient group of technical men to be organized, one organization that embraces them all. Reasons for this are obvious. This organization may be an association of local societies and sections of national societies, or it may be a society admitting to its membership men of all branches of the profession. Examples of both forms of organization exist in a number of places. Local organizations should have large measures of autonomy, but should conform to approved types and standards.

Logically, the next step in organizing would be the combining of these local organizations into one or a few national societies, so that the loyalty, interest, comradeship, and activities naturally developed by the local organizations would flow to the national societies. But at this step the difficulties increase. Many engineers cannot become active members of local organizations, because of distances from headquarters; others do not desire local membership. If there were only one national society, many of the difficulties of scheming a system of organization would disappear; but there are, and probably for some years will be, several national societies of importance, and in each local organization there will be members of two or more national societies. A number of plans have been submitted to me for overcoming these difficulties. None is wholly acceptable. These problems lie at the bottom of the tasks of the Committee on Development of the American Society of Civil Engineers, and of the Committee on Aims and Organization of the American Society of Mechanical Engineers, and similar committees appointed by the other societies. Many engineers are giving them thought.

There are said to be approximately 400 organizations of engineers in America, of various kinds. Of these, about one-quarter are the leading national societies and their local sections. In general, the remaining societies have no official relationship, excepting the associations of local societies and sections in a few communities. Consequently, the engineering profession, before the public and Government, has no one organization which represents it as a whole, as have the medical profession, the lawyers, the chemists, the architects, the Chamber of Commerce and even labor. In the memberships of the Founder Societies, aggregating 35,000 engineers, there have been variously estimated to be only one-third to one-sixth of the total number of engineers in the country. The engineering profession lacks solidarity.

Not a little of the dissatisfaction voiced in various quarters as to the shortcomings of the national societies

grows out of ignorance or lack of apprehension of benefits actually received. In no small measure the complainants are at fault in not making better use of the facilities provided and the means of information put within their reach. Furthermore, some important benefits of membership in large technical societies are intangible and not capable of definition; not a few persons overlook these. Nevertheless, there are causes for reasonable dissatisfaction. The societies are endeavoring to remove these as they are recognized and remedies can be found. Humanity and its institutions will never be wholly rid of dissatisfaction, and to this truism engineers are no exception.

Quotes President Main's Address to Mechanical Engineers' Society

In this connection, a quotation from the presidential address of Charles T. Main to the American Society of Mechanical Engineers, December, 1918, is interesting reading:

In the *Monthly Bulletin* of the American Institute of Mining Engineers, March, 1918, there appeared the following:

"The vision dwells in the minds of many that ultimately these four great societies, lightening the emphasis they place upon their differences, may see the time when, for the solidarity of the profession, for their best interests, as well as for the increase of their influence on the country at large, they may become one great national association of engineers. With the gain in power and prestige inevitably following such an aggregation, freedom from individual development may be achieved through division along the lines of technical interests, which might either follow the present four grand divisions or be more minutely subdivided.

"An organization of this sort could and probably would be more strictly professional than any of the four have been heretofore, and through the prestige and power of its numbers could establish standards of ethical conduct for its members, violation of which would bring, grave consequence."

This great vision is worthy of the most careful consideration and might be carried with safety to a point where the national societies would be gathered in under one executive head, without any one losing any vital portion of its individuality.

This would be a great step in advance and perhaps as far as we should go for some time to come.

Whatever scheme of organization be ultimately selected, it must be flexible, so as to meet successfully constantly changing conditions, and it must provide for both technical and social requirements of the membership, while maintaining high standards. "Social requirements," is here used to mean, in addition to social intercourse among members, services of the organizations to Government and to the public, and services to engineers individually, such as assistance in securing engagements and better standing in corporate and Governmental employment. Technical and social functions probably will be best kept distinct. Some engineers even suggest separate organizations; but at present prefer separate departments of one organization or of a federated group of organizations.

The United Engineering Society

So far as known, none of the leading organizations has stated a definite policy on these questions. Opinions herein expressed are only personal. The statements in this paper are merely a contribution to the general discussion of this subject by one who for several months has had especial opportunities for learning the opinions of others and gathering a little information.

As regards the joint activities of the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, the present organization seems involved; and even some members of the governing bodies of these societies have difficulty in keeping relationships straight. It is, however, not so complex as some persons assume. It may be simply stated as follows. The four Founder Societies named have joined in creating the *United Engineering Society* to hold and administer property and to perform other broad functions for them. At their request the United Engineering Society has established three departments—the Library Board, the Engineering Foundation, and Engineering Council.

The Engineering Societies Library has possibilities for active usefulness to the engineering profession and to the industries of this country. Its present passive services are good and of great value, but the library can do much more. Funds are needed at once for complete recataloging of the books, for strengthening the collection of books, and for instituting new lines of service. The books of the societies have been brought together, but they have not yet been assembled as one library. Never, except during the war, has it been so important that all useful recorded technical information should be fully and quickly accessible to engineers—not only to those in the New York district, but also to those scattered throughout the whole land.

Engineering Foundation and Engineering Council

The Engineering Foundation now has an endowment of $300,000, yielding an annual income of $15,000. It rendered vital financial assistance to the National Research Council at the latter's inception in 1916, and for the year terminating in September, 1917. That council performed services of great importance to the Government during the war. For the future it already has in hand many projects. One of the most important of these is the promotion of industrial research, in which the Engineering Foundation is coöperating. The Engineering Foundation investigated a scheme for spray camouflage of ships; is conducting long-time tests on the wear of gears, and is making a research into the selective control of wireless communication. It has offered to undertake a "survey of existing engineering organizations, and from information thus developed to formulate a series of constructive recommendations which may be serviceable in guiding the further development of local and national engineering organizations, in their relations to the profession of engineers, to the public, and to one another." Other projects are being studied, but cannot yet be announced. Engineering Foundation's policy is to devote its energies and resources to undertakings of broad application, such as bringing about and stimulating coöperation among existing agencies engaged in research and outlining programs and organizations for research in specific fields.

The Engineering Council, since its organization meeting on June 27, 1917, has made progress in exploring its proper field of activity and fixing some of its boundaries. It has accomplished much useful but negative

work. In other words, its rejections have been important and have consumed much time. But there are noteworthy constructive achievements, also, on the credit side of its records. During hostilities the Council rendered no small aid to the Government through the American Engineering Service, which procured thousands of engineers for the War, Navy, and other departments, and through the War Committee of Technical Societies, which assisted the Naval Consulting Board and the Army General Staff in examining scores of thousands of suggestions for naval and military devices. Through efforts of its public affairs committee, the Council aided in having the military draft adjusted to permit the continuance of training in the engineering schools of the vitally necessary technical men. Through the industrial affairs committee vigorous opposition was offered to "anti-efficiency" legislation in Congress. Ten days after the signing of the armistice, the Engineering Societies Employment Bureau, with the four Founder secretaries as its board of directors, was substituted for the war-time American Engineering Service. The fuel conservation committee acted in a consulting capacity to the Fuel Administration and the Bureau of Mines in securing war economies, and is continuing its much-needed services into the era of peace. The water-conservation committee is prepared to promote right, and to oppose wrong, national or state Governmental actions relating to water-power or other utilization of water, by supplying statements of facts rather than joining in controversial support of or opposition to any particular measure. The license committee, with members judiciously distributed throughout the country, is collecting information on the licensing of engineers by the various states, and is preparing to render proper assistance in these matters whenever needed. The patents committee, coöperating with other similar bodies, is preparing important action for the improvement of the patent law and practice. During the spring and summer, the secretary visited groups of engineers representing the local societies and sections of national societies in 20 different cities from the Atlantic seaboard to the Pacific Coast. In 30 or more communities local correspondents have been selected for direct communication between Engineering Council and engineers at distances from headquarters. Furthermore, important projects of interest to all engineers are in preparation and may soon be announced. One of these is the formation of a national service committee, which is to have an office in Washington, as the representative of American engineers at the national capital.

All aims and endeavors of engineers through their national and local societies and their joint instrumentalities must be pervaded by a sincere spirit of service, not alone of one to another, but by all to the community, the state, and the nation. Such public service by engineers, architects, chemists, scientists, doctors, lawyers, and clergymen is our professional obligation, the *noblesse oblige* of a free and democratic people. Each profession has its distinct service to perform. In each profession there are big men and small men; each must contribute according to that which he has. Service is the only true stepping-stone to that eminence which alone is worth attaining. Greater opportunities have never opened to American engineers than those which confront them in these rapidly passing years of war and "reconstruction."

Committee Analyzes Track-Elevation Costs or Rock Island Work in Chicago

Book Figures Are Redistributed, Freight Charges and Other Elements of Expense Estimated and Added In, to Obtain Complete Unit Costs for Fifty Items on $2,700,000 Improvement

UNIT costs of the track-elevation work of the Chicago, Rock Island & Pacific Ry. have been the subject of an extensive study by a committee of valuation engineers. An organization known as the General Committee of the Chicago Zone Railways has been considering for more than two years the special valuation problems presented by the network of railroads in the Chicago terminal district. Between Aug. 1, 1912, and Dec. 31, 1916, track-elevation from 72nd St. to 90th St., a distance of 2½ miles, was carried on by the Rock Island as a continuous operation, at a book cost of $2,703,196.75. The Rock Island completed an extensive study of the unit costs of this work, the results of which were reviewed and criticized by a subcommittee of the general zone committee, created for the purpose. The subcommittee is known as subcommittee 14, and Robert H. Ford, principal assistant engineer, formerly engineer track elevation of the Rock Island, is its chairman. The object of the investigation was to determine the correct methods for the distribution and probating of certain charges that appear on the books of the auditor, set up under account 43, later referred to, and the proper basis for estimating costs that do not so appear.

The report is divided into three books. Book 1 is simply an accounting analysis, or summary, of the auditor's records. Book 2 is an engineering analysis of the charges set up in book 1, which has been made for the purpose of obtaining the cost per unit of work. It embraces labor, material and work-train service costs as set up in book 1, and in addition freight on material over company lines. In this book the items in book 1 are analyzed and redistributed, and the units of work done allocated to the book charges for each class of work, such as filling, excavation and concrete. Book 3 is an addendum to the engineering analysis in book 2 and consists of added items of direct expense which affect the unit cost but which for various reasons have not been included in the book charges, these being added in order that the entire direct unit cost may be derived.

Book 1—Accounting Records

In book 1 the accounts are set up in conformity with the Interstate Commerce Commission classification—

(1) engineering; (2) land for transportation purposes; (3) grading; (6) bridges, trestles and culverts, and so forth. These are subdivided into the items of work—account 6, for example, containing 37 subaccounts, including such items as excavation, sand, cement, wood forms, drainage. Across the page these are divided into labor cost, material, quantity and cost, and work train hours and cost. The labor column includes only such labor as is covered by the pay rolls of the track-elevation forces. All amounts paid by voucher to contractors or others, whether for labor or material or both, are included in the material column. The material column does not include freight charges on the company's own lines. On July 1, 1914, the I. C. C. classification was changed to provide that thereafter such charges should be added on completion of the job, but as the work was still in progress when the analysis was being made the charges were not added in book 1. They were included in the material column in book 2. Under account 43, other expenditures and suspense, the company carried a large number of items that under a different policy would perhaps have been charged to other accounts, the company's policy being that doubtful items could better be classified upon completion of the work, after careful study. One hundred subaccounts, totaling $594,826.03, were carried under account 43.

Book 2—Engineering Analysis

The task in preparing book 2 was to subdivide and regroup the subaccounts of book 1 to cover actual inventory or physical units, adding in the computed freight charges for material hauled over the company's lines and allocating the suspense items in account 43, but otherwise retaining the I. C. C. classification. Thus, in accounts 3 and 6 the items for forms appearing in book 1 are incorporated in the concrete costs for book 2, and on the other hand the single item for concrete cribbing in book 1 is subdivided to cover the making and the handling and setting of two types of cribbing. "Drainage" in book 1 is replaced by "Drainage—4-in. Tile" and "Drainage—6-in. Tile" in book 2. Detailed statements of what the items in book 2 consist of, where the materials were obtained and how they were transported, are included in the report.

Numerous different bases were used in distributing the items of account 43 to the other primary accounts. General work-train service and repairs to material cars were allocated to benefited items in all of the other accounts, except engineering and land in the ratio of total costs of those items; handling material and general freight charges to benefited items in the same accounts as indicated above, in the ratio of the material

costs of those items; camp, repairs to small tools, to tool cars and to bunk cars, to benefited items in the same account as above, in the ratio of labor costs of those items; temporary trestle to "filling," account 3, and "concrete," accounts 3, 6 and 16, in the ratio of yardage; material yard items and temporary tracks to benefited items in accounts 3 to 27, in the ratio of weights of material; temporary tracks at source of supply of materials to "filling," account 3, "ballast," account 11, and all items in which sand and gravel were used in "concrete," accounts 3, 6, 15, 16, 26 and 27, in the ratio of yardage.

Book 3—Additions to Book Charges

Book 3, as previously explained, is an addendum of the engineering analysis shown in Book 2. "It consists," states the committee's report, "of added items of direct expense which materially affect the unit cost, but which, for various reasons, have not been included in the book charges." One element which is not included in these additions is general overhead charges—organization expenses; general officers and clerks; law; stationery and printing; taxes; interest during construction, and other expenses, general. Special studies have been made of the various items to determine whether the figures indicated in book 2 contain omissions. The same general classes of items, irrespective of the account to which they have been charged, are regrouped to show the average unit cost. Thus, the concrete items in the different primary accounts of grading, bridges, trestles and culverts, stations and office buildings, and so forth, were merged, but the different *classes* of concrete as plain, reinforced, etc., were kept distinct. On the other hand, certain items dependent on local conditions, such as station buildings, rail and other track material, were eliminated.

Engineering in book 2 was carried on a basis of percentage of all accounts except engineering itself and land, and was shown as 6.185%. Two additions were made in book 3. In connection with the inclusion of freight charges it was estimated that the additional work required the time of at least one accountant and one clerk during the period covered by the analysis, this amounting to 0.408%; the other addition was for divisional overhead, embracing charges for services of the chief engineer, bridge, signal, building and other staff engineers and their office forces. This was estimated by a special study to be 0.680%, and the two increments bring the percentage for engineering up to 7.273.

Special Studies

Following is the statement regarding the item for cinders. "Cinders have been included in the book accounts at an arbitrary rate of 20c. per yd. This is lower than actual cost, and an independent study is in process to determine the cost. Preliminary to this determination an estimated amount has been made based upon the switching rate directed by the Interstate Commerce Commission and the State Public Utilities Commission of Illinois, viz., 1c. per hundredweight (60,000 lb. minimum per car) to the originating line, plus ½c. to the delivery line, or equal to a minimum of $6 per car for the originating line, plus actual cost of handling on the delivery line, the latter being assumed as requiring four days' service for use of car at 35c. per day (demurrage rate then prevailing), plus the cost of switching, estimated as equivalent to 10 miles at ½c. per ton per mile. Computed upon 35 cu.yd. per car (which is the estimated average yardage of the loads of cinders covered in this analysis) and allowing 1500 lb. per cubic yard, the rates indicated above amount to $8.00 per car or 25.1c. per cubic yard. The difference between this cost and the arbitrary cost of 20c. per cubic yard or 5.1c. is added to class A cinders.

A special study of the cost of treated crossties resulted in an addition of 51.2c. per tie, the total cost including freight charges from the treating plant in Missouri to the distributing yard. Similarly, another study added 26.5c. per tie for untreated crossties.

Unit Costs Derived

The accompanying table shows some of the larger items—the unit costs (with freight charges) derived in book 2 and the estimated additions properly included. In some instances, costs in two or three kinds of units have been figured. In the use of the data, it is pointed out, judgment must be applied to evaluate the affecting conditions—not only the character and composition of the finished structure, but the hampering or facilitating conditions under which it was built. Thus, as concrete for retaining walls, it is pointed out, is ordinarily cheaper to place than concrete for abutments, because the work can be laid in larger sections, so all of the concrete work covered by the analysis is held to have cost less per yard than in the average track-elevation program in Chicago, partly because the right-of-way was less restricted and it was less difficult to prosecute the work and still maintain traffic, and partly because the Rock Island, having a large amount of concrete to place on the job, was especially organized for that class of work. On the other hand, it is thought that a similar study of track elevation on the Chicago & Western Indiana R. R., where filling is the principal item and the work has been organized for that, would show a much lower unit cost for grading and a much higher one for concrete. The report describes in considerable detail just what, as to materials and method of fabrication, was involved in each item, and the report, aside from giving a definite basis for fixing prices on the work it covers, aims to show the unreliability of undigested book costs, to suggest a method of analysis to determine correct figures, and to present a fair guide as to what those figures should be.

Besides Mr. Ford, chairman of the subcommittee, its members are Joseph Weidel, valuation engineer of the Santa Fé system; J. H. Roach, valuation engineer of the New York Central; E. B. Crane, assistant valuation engineer of the Chicago, Milwaukee & St. Paul; W. C. Bolin, pilot engineer of the Baltimore & Ohio; D. J. Brumley, valuation engineer of the Illinois Central; G. W. Hand, valuation engineer of the Chicago & North Western; A. Montzheimer, chief engineer of the Elgin, Joliet & Eastern, and L. S. Rose, valuation engineer of the Cleveland, Cincinnati, Chicago & St. Louis.

Supreme Court Fixes Responsibility of Contracts

Through oversight in the preparation of the article with above title published in our issue of Dec. 26, 1918, p. 1167, the author's name and title were omitted. The article was written by George A. King, of the Bar of the United States Court of Claims. Washington, D. C.

Emergency Shipbuilding on Lakes Handled By Erection Cranes of Many Types

Side Launching Imposes Special Requirements—Old and New Cantilever Cranes—Gantries Do Successful Work—Tower Cranes Installed During Past Year—One Crane Per Berth Now Thought Necessary

SHIP-ERECTION cranes of many forms are giving efficient service in the rush work of building ocean-going ships for the Emergency Fleet Corporation in the Great Lakes yards. Side-launching, which these yards practice exclusively, imposes on crane layouts and crane types requirements which lead to pronounced differences from the equipment found in the seacoast end-launching yards. As the building berth lies along a dock wall and the ship is launched over this wall, cranes and material cars can operate along one side only. This condition, and the common arrangement of grouping berths on a pier, have controlled the development of the shipbuilding cranes. Recent types, however, are such as to suit any berth arrangement equally well. The service obtained from the various cranes appears to depend more on the space layout of berth, craneway and storage facilities than on inherent characteristics of the cranes.

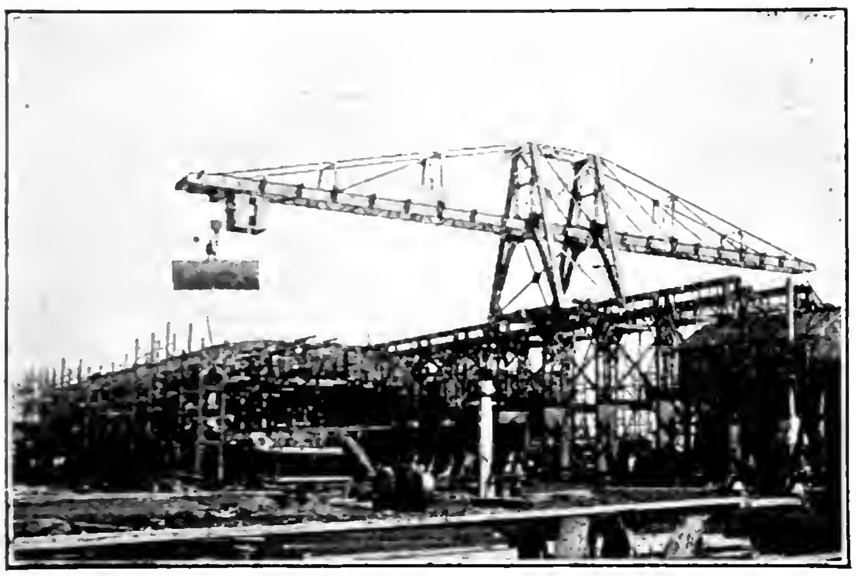

FIG. 1. DOUBLE CANTILEVER CRANE COVERING FOUR SHIPBUILDING BERTHS AT SUPERIOR YARD

Revolving-jib traveling cranes are newcomers in the Lakes yards. Many have been installed during the past year. They are traveling portal-frame towers on which are mounted revolving locomotive-crane or equivalent superstructures.

All the cranes built for Lakes shipyards prior to the present year are either gantry or cantilever trolley bridges. These machines had proved entirely satisfactory, but as additional crane service was needed at once revolving-jib cranes, which could be obtained most quickly, were introduced.

While even the oldest of the trolley machines, as that shown by Fig. 1, are meeting the demands of rush work, evidence of progress is given by the fact that the more

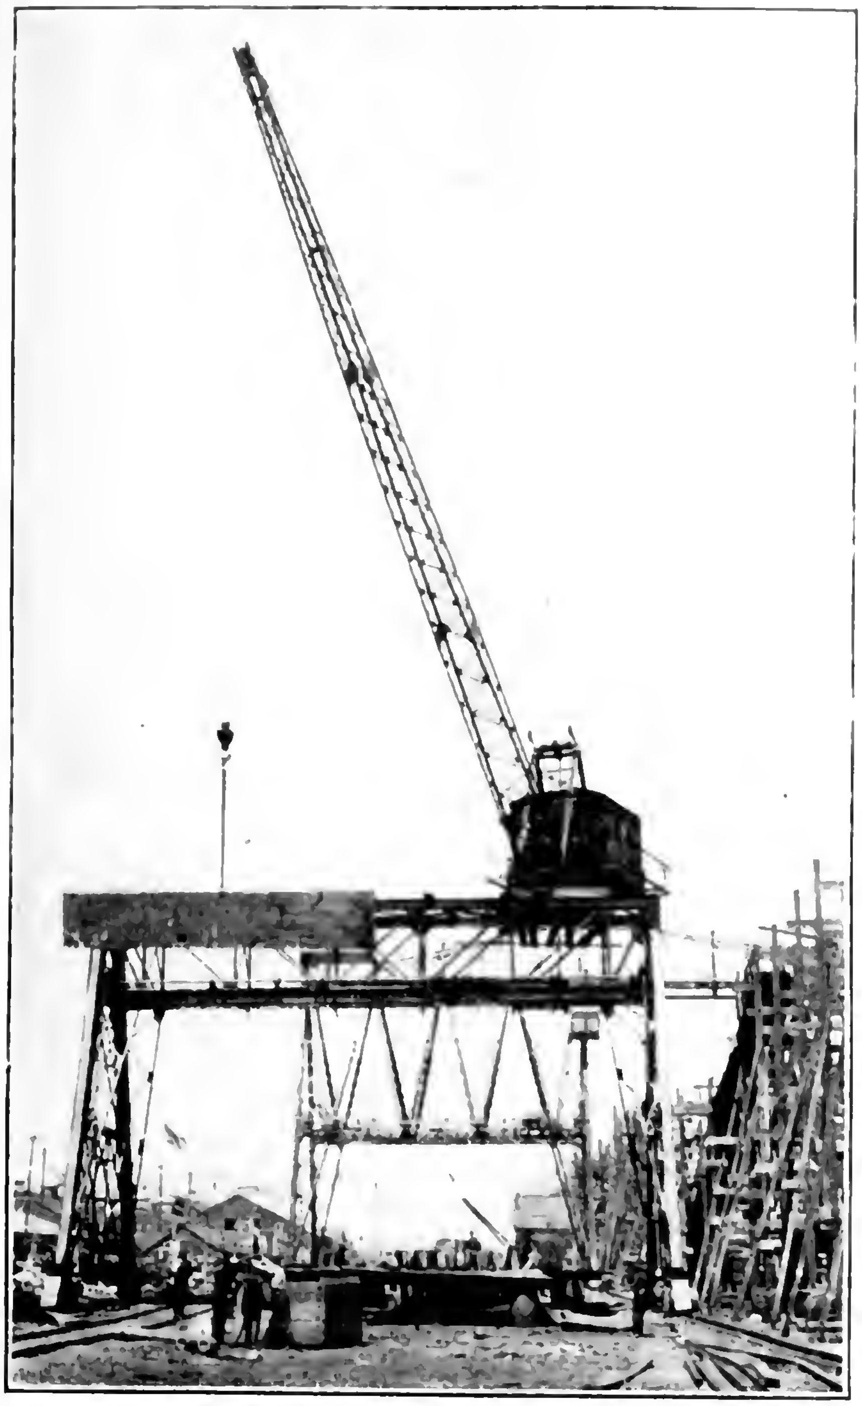

FIG. 3. LOCOMOTIVE CRANE ON WIDE GANTRY BASE, IN SERVICE AT ECORSE

recent ones have proved superior in speed and operating convenience. The best speed records have been achieved in yards equipped with cranes of relatively recent design. It is noteworthy that the cranes which made the two fastest shipbuilding performances were designed by shipyard men; and one of these performances made a world's record for shortest time from keel-laying to launching.

Three Main Types Represented in Various Forms—Except for the revolving cranes of the present year, the Lakes yards are equipped with (1) cantilever cranes reaching out over the berth from its land side, leaving the other side clear to permit launching, or (2) gantries which span the berth and find support on an outboard track removed at the time of launching. The operation of removing and replacing the track, together with the fact that the berth is without crane service in the interval, constitutes a *prima facie* argument against the gantry type, but this is invalidated by the successful work of the gantries. Moreover, gantries as well as cantilevers are represented among the new cranes added during 1918.

A. C. Payton, superintendent of the American Shipbuilding Co.'s Lorain, Ohio, yard, where gantries have been used since the foundation of the yard in 1899, states that the cost of removing the outboard track to clear a 261-ft. ship is negligible, as a gang of 11 men does the work in 1½ days, and in any event part of this time is required for taking down scaffolding. He considers the Lorain gantries the best ship-erection machines on the Lakes. C. B. Calder, president of the Toledo Shipbuilding Co., Toledo, Ohio, is equally pronounced in favor of gantries, of which the yard has three; the cranes can go into service within two hours after a launching. The Globe Shipbuilding Co., Superior, Wis., which began operations during the past two years, has installed gantries as giving the most efficient utilization of the yard space.

Cantilever cranes are the oldest as well as the newest of shipbuilding cranes of the Lakes, however. Four different arrangements are in use, represented by sketches A to D, in Fig. 2. Trestle-supported cranes with cantilever arm projecting to one side (sketch A serve riverside berths at the Cleveland yard of the American Shipbuilding Co. Similar trestle machines cantilevering to both sides (B) form the equipment of berths grouped on piers at three other yards of the same company, at Wyandotte, Mich., South Chicago, and Superior, Wis. All these machines are about 25 years old.

Recent cantilevers are shown at C and D. One-side cantilever bridges carried on gantry bases running on tracks on the ground (sketch C) are used at the Ecorse, Mich., yard of the Great Lakes Engineering Works; the berths are on piers, and two cranes set back to back on separate tracks serve the two sides of the pier. The Manitowoc Shipbuilding Co., Manitowoc, Wis., has cranes of the same structural type, but running on low trestles 6 to 12 ft., high (D); the berths here are arranged along the river bank, and, as supply tracks are located both within the gantry width and back of it, the trolley runway is cantilevered out backward a short distance, so that it commands both tracks. A gantry-base double cantilever similarly supported on low trestles (Fig. 8) is in use at South Chicago.

Gantry cranes, used in three yards, are of as many different forms, distinguished by their track arrange-

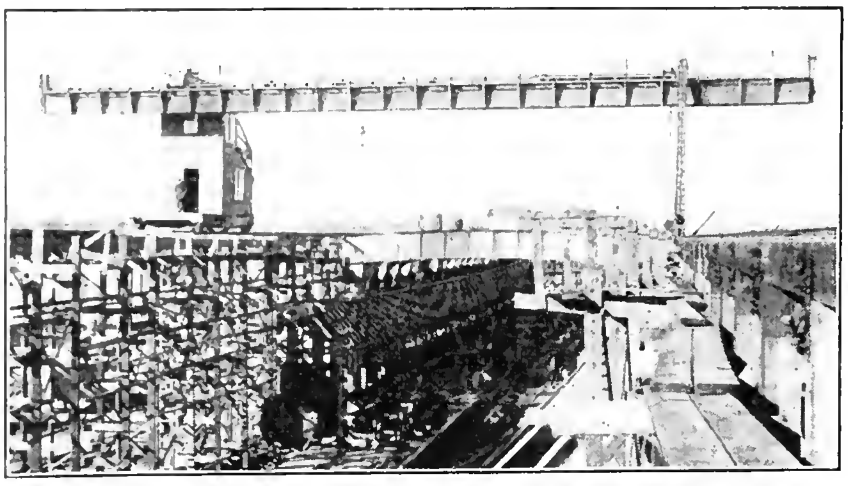

FIG. 4. ONE OF THE GANTRIES AT THE LORAIN YARD

ment. At Lorain the outboard track is carried on a line of columns (E, Fig. 2, and view, Fig. 4). The Toledo gantries have their outboard track on the ground (F). Both these have a trestle to carry the main or inboard track, and the bridge has pin or hinge connections to its supports at both ends. The cranes of the Globe Shipbuilding Co., however, are of true gantry type (G)

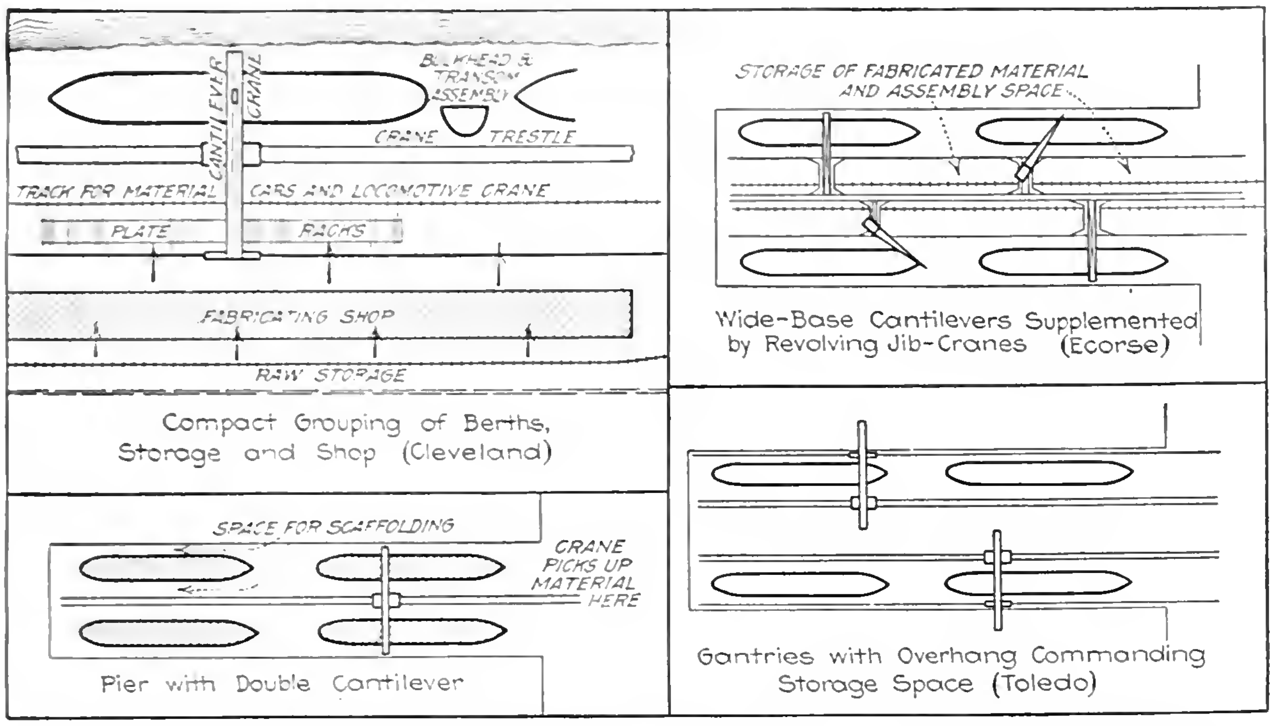

FIG. 5. STORAGE AND HANDLING OF MATERIAL AT BERTHS ARE AFFECTED BY CRANE TYPE AND ARRANGEMENT

and have both tracks on the ground. Removing and replacing the outboard track (and its supports, in the case of the Lorain arrangement) is in all cases done by the crane itself.

Revolving-jib cranes as installed during the past year comprise regular locomotive-crane superstructures, re-

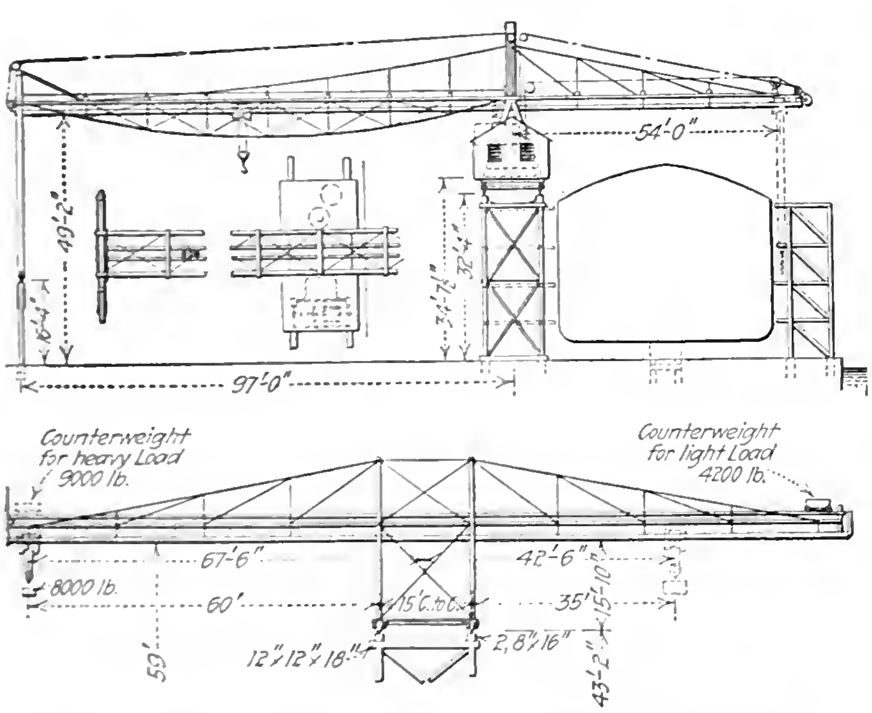

FIG. 6. EARLY SINGLE AND DOUBLE CANTILEVER CRANES STILL GIVING GOOD SERVICE

volving on a fixed turntable seated on a portal-braced tower (sketch H). Even where the supporting tower is widened out to gantry proportions as shown by the dotted line (new cranes at Ecorse), the jib hoist does not traverse on the tower. Such locomotive tower cranes have been installed by the American Shipbuilding Co. at Buffalo, Wyandotte, South Chicago and Superior, to serve new berths; and by the Great Lakes Engineering Works at Ashtabula and Ecorse, and the Manitowoc Shipbuilding Co., to supplement existing cantilever cranes. One of these machine is shown in Fig. 3. A slightly different type of revolving-jib crane was adopted by the McDougall-Duluth Co. late last year in equipping its yard at Duluth, Minn.

Old Cantilever Cranes Under Various Service Conditions—That the berth conditions and the arrangement of the surrounding space are of vital bearing on the results obtained from a particular crane appears in pronounced manner from comparison of the six old cantilever cranes to which reference has already been made—two one-side cantilevers at Cleveland, serving three berths, and four double cantilevers at Wyandotte, South Chicago and Superior, generally serving a group of four berths. All were built in the early '90's, and two of them are of the rod-braced light truss type characteristic of coal-handling machinery in that period. The Cleveland and Wyandotte cranes, Figs. 6 and 7, were built by the Brown Hoisting Machinery Co. for the F. W. Wheeler Shipbuilding Co.'s yard at West Bay City, Mich., and were removed from there later by the new owners, the American Shipbuilding Co. The Superior crane. Fig. 1, was installed about 1896 by the Wellman-Seaver-Morgan Co. when Capt. Alexander McDougall built his whalebacks at that yard.

At Cleveland the shop, berths and cranes are in closely-knit grouping, as sketched in Fig. 5. The shop lies directly back of the crane runway, and delivers either to the cranes or to storage racks in the runway. Material, therefore, has to move only a short distance in going from shop to ship, and a given crane capacity can erect more material than where a longer path is involved. Due to this fact, and also to unusually able and energetic management, the yard has been able to make an excellent shipbuilding record during the past two years, in spite of having much ancient, inadequate equipment and cramped facilities. Not only are the cranes old and of light capacity, and in need of very careful maintenance, but the shop, which is even older,

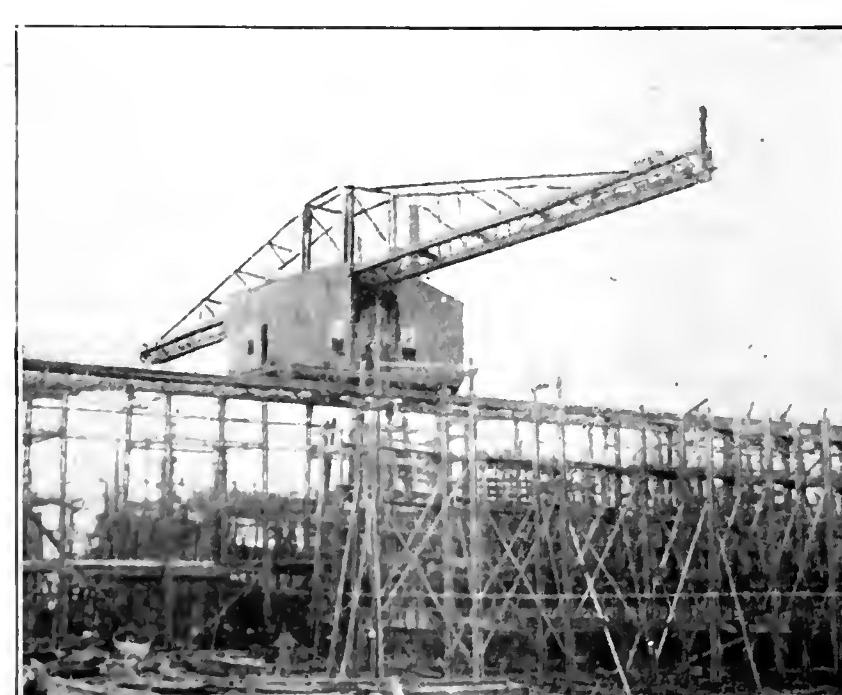

FIG. 7. WYANDOTTE DOUBLE CANTILEVER, ORIGINALLY AT WHEELER YARD, WEST BAY CITY

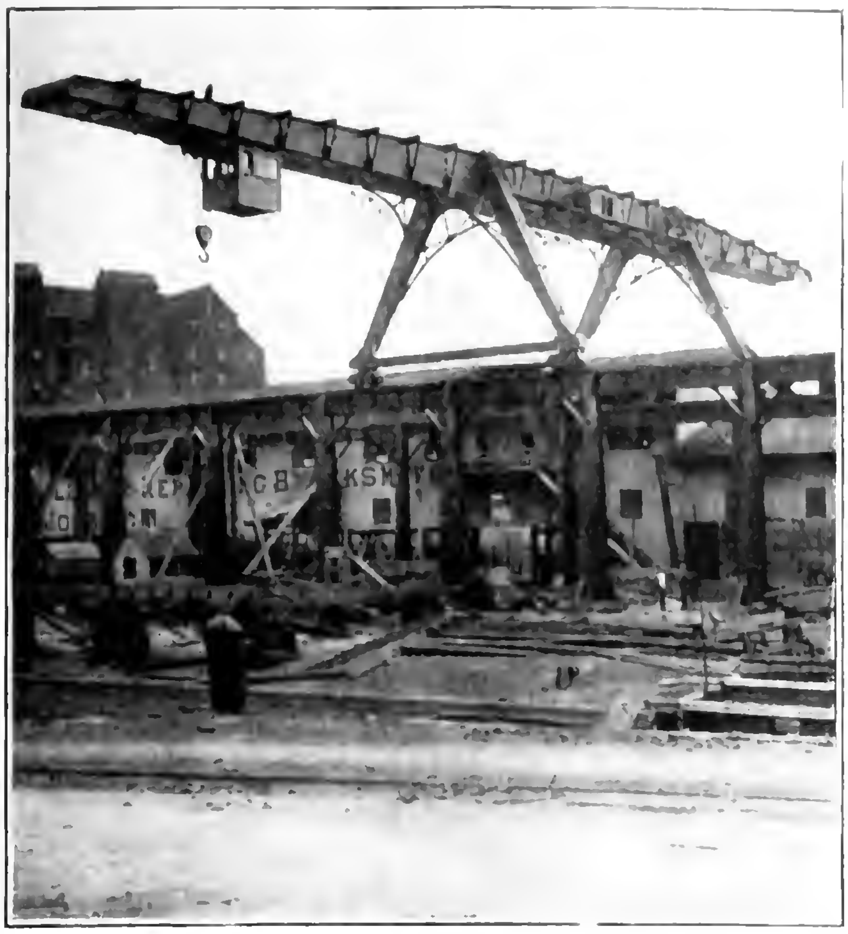

FIG. 8. UNEQUAL-ARM CANTILEVER CRANE ON GANTRY BASE, SOUTH CHICAGO

is badly cramped in layout and lacks handling facilities. The hoisting capacity of the cranes is three tons, and the speeds are: Lifting 250 ft. per minute, trolley travel 1000 to 1200 ft. per minute, bridge travel 300 to 400 ft. per minute.

Very different layout is found at the berths equipped with the double cantilever cranes, as Wyandotte and Superior. These are berths arranged in a group of four on a pier, down the center of which is placed the trestle of the double cantilever, as sketched in the small-scale plan in Fig. 5. No space is available for supply tracks between the ship and the crane trestle, or under the trestle. In fact, there is no way of bringing ship parts or other material from the inshore end of the pier except by the crane itself. Under this condition, and with only one hook for four hulls, these berths have crane service that is more limited than any other on the Lakes.

Experience in the South Chicago yard, where there is a Brown double cantilever similar to that at Wyandotte, is that shipbuilding on the berths served by the double cantilever is under a handicap in regard to crane service. Edward Morris, assistant superintendent of the yard, says that the crane is far from equal in capacity to the locomotive tower crane which has been installed to serve a new berth.

Surprisingly satisfactory service, however, has been given by the Wyandotte crane, according to the yard officials. A special method of operating the crane contributes to this. The crane platform is used as a magazine when material is handled from the shop to the berths, and this practice economizes in crane travel and saves time. Six or eight shell plates or other ship parts are piled at once on the truck platform of the crane carriage (see end elevation sketch at B, in Fig. 2) and are distributed to the ship in a single trip. While one plate is being run out on the trolley, the crane helper fastens lifting chains to the next plate, so that when the hook returns no time is lost in picking up a new load. The crane has a lifting capacity of 4 to 12 tons at speeds of 300 ft. to 80 ft. per minute; its trolley speed is 1000 to 1200 ft. per minute and its travel speed about 500 ft. per minute. It is reported to work as fast as the needs of the berth demand. At the time of writing, the yard officials were of the opinion that the double cantilever crane is equal in service to three of the tower cranes recently provided for the new berths of the yard, but called attention to the fact that the old crane has the advantage of skilled operators, the new cranes having been in service too short a time to have been brought up to best performance as yet.

An interesting change was made in the Wyandotte crane (Figs. 6 and 7) a few years ago. The traveling counterweight, which is equal to about half the maximum load capacity, was cut down to one-fourth or less of its original amount. Though this change decreased the stability of the machine, a 14-ton load has been carried at extreme reach without lifting the far wheels of the crane off the track.

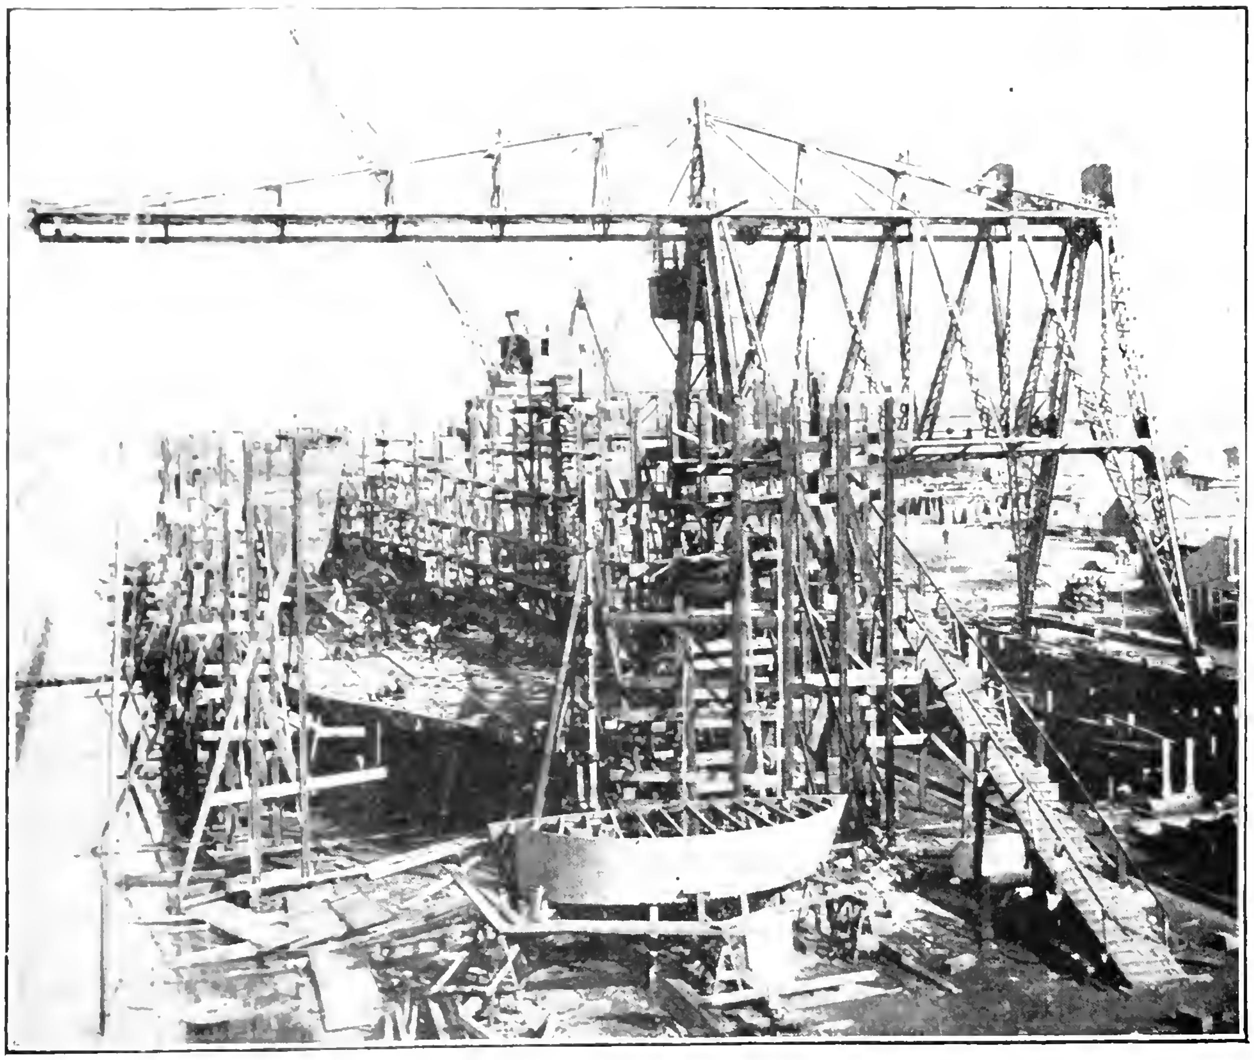

FIG. 9. GANTRY-BASE CANTILEVER AT ECORSE YARD

Another early cantilever, Fig. 8, shows more modern detail design, though built in 1898. Its trolley runway is supported by a gantry base resting on separate lines of columns. This crane is in service at South Chicago. Its structural parts are of plate-girder makeup, as commonly used by its builders, the Wellman-Seaver-Morgan Co. This machine, at present serving only a single berth, has been giving very satisfactory service. Its capacity is 10 tons, the maximum lift about 50 ft., the height of track rails above the ground 22 ft., and the total length of girders 195 ft. It was built for a Buffalo yard, and was later moved to South Chicago.

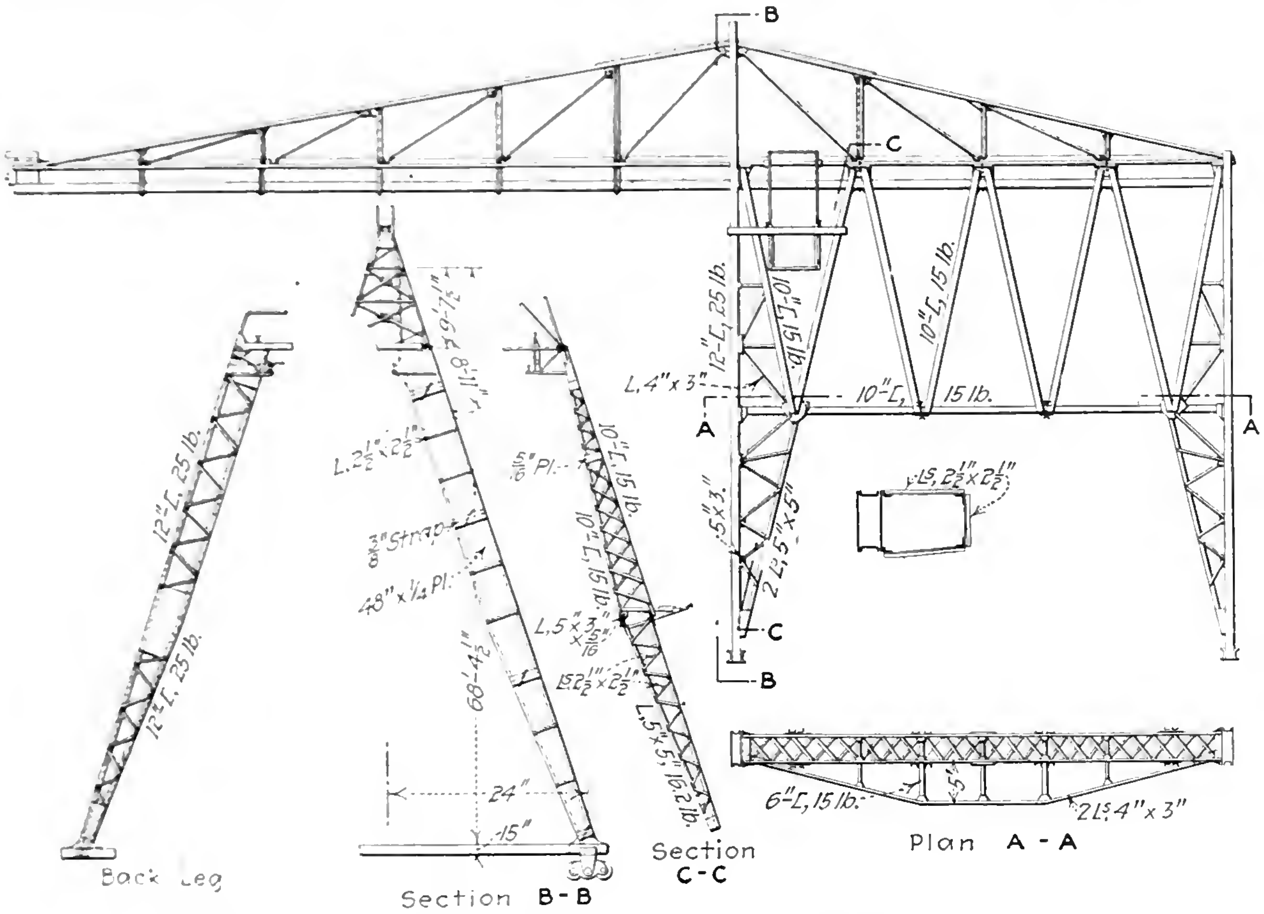

FIG. 10. OUTLINE DRAWING OF ECORSE CANTILEVER CRANE

Wide-Base Single Cantilevers Are Doing Fast Work—Remarkable efficiency was shown recently by the shipbuilding cranes of the Great Lakes Engineering Works at Ecorse, Mich., in building the 3500-ton steamer "Crawl Keys" in 14 working days. The berth system is such as to utilize most fully the advantages of short-travel material supply afforded by the layout. This feature, which was brought out in a description of the Ecorse pre-assembly system printed in *Engineering News-Record* of Dec. 12, 1918, p. 1076, is the determining factor in the performance of the cranes. The load capacity (seven tons) and the crane speeds compare closely with those of other ship-erection cranes in the Lakes yards.

The Ecorse cranes, Figs. 9 and 10, were originally designed by the Wellman-Seaver-Morgan Co., but the lower part has been rebuilt at the yard. Two were built in 1903 and the other several years later. Electric current for the operating motors is supplied by contact wires carried on short poles just back of the rear gantry leg. The control stand is in a cage at the forward end of the gantry frame, just under the trolley rail.

By combining the operator's cage with the hoist trolley, the Manitowoc Shipbuilding Co. has added a new operating feature to the gantry-base cantilever crane. The yard has four of these machines at present, all of them designed in the yard; the last was installed during the present year.

An old coal unloader was the starting point of the first crane, shown in the view, Fig. 11, Gantry legs were added to it, with the necessary travel machinery. The bridge was strengthened by trusses between the front and rear legs and by cable guys run from a frame erected over the forward legs down to the panel-points of the cantilever portion. An I-beam runway carries a two-hoist Pawling & Harnischfeger monorail trolley with operator's cage. This machine, built in 1903, has proved its value in the service it has rendered since then, and on the basis of this experience the same type was adopted for three new cranes installed during 1917 and 1918. Fig. 12 shows the structure of the latest of these cranes, built last spring by the Wisconsin Bridge & Iron Co. With forward and rear cantilevers of 80 ft. and 12 ft., it commands a supply area 59 ft. wide and a berth area 80 ft. wide. The two 1917 cranes, built for a double berth hitherto handled by the first crane, are of substantially the same design, but have a track gage of 58 ft., so as to be able to use the existing trestle. Berth 4, newly built, is served by the oldest of the cranes, transferred from the double berth, so that one crane per berth is provided, while berths 5 and 6, the newest, are equipped with a locomotive tower crane, which, together with a second one yet to be installed, will handle these berths and the adjoining fitting-out dock.

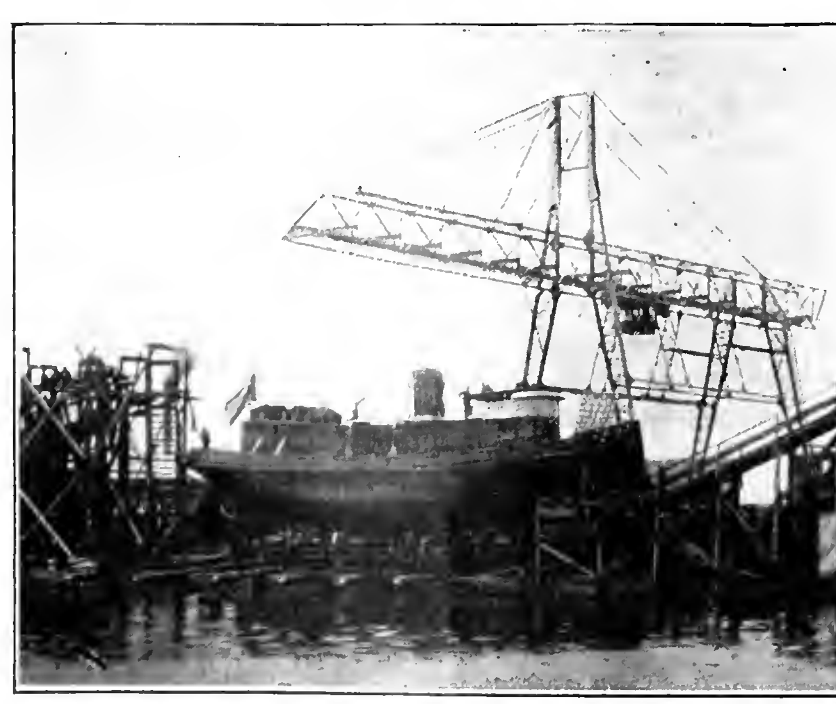

FIG. 11. CANTILEVER BUILT FROM AN OLD COAL-UNLOADING BRIDGE

A speed record in shipbuilding was made by the

Manitowoc cantilevers in July; on July 10 a keel was laid and on Aug. 7 the hull of the "Corsicana" was launched, after only 24 working days of building. Two cranes were used on the ship and a night crane force was run, but bolting and riveting were done only by the ordinary 10-hour day shift.

Gantry Cranes in Three Yards—During the same time exactly the same speed-record was made by the Lorain yard of the American Shipbuilding Co. The keel was laid July 1, and the fully riveted hull of the "Lake Deval," with tail shaft, propeller and rudder in place, was launched Aug. 8. Only one crane was available for this work. It was a gantry, of a type used at Lorain for 20 years. In a single 10-hour day this machine made 230 lifts, working up to its limit of speed, according to A. C. Payton and Charles Marlow, superintendent and assistant superintendent of the yard.

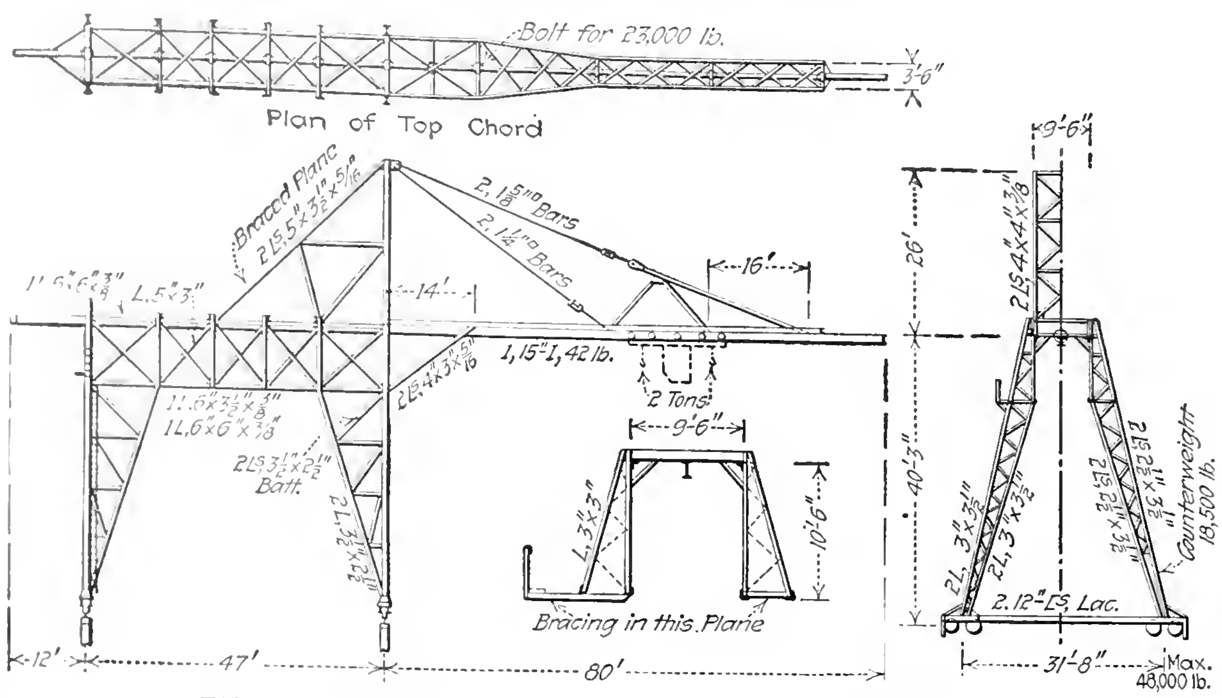

FIG. 12. NEW CANTILEVER CRANE OF MANITOWOC YARD

Berth conditions are substantially the same at all of the yards using gantry cranes. Material is picked up by the gantries from a rear cantilever extension of the trolley bridge in most cases. A few of the cranes have a span sufficient to cover a wide supply area alongside the berths.

Of the four gantries at Lorain, two built in 1899 and two in 1906, the later ones are represented by Fig. 13, from a drawing of the builders, the Wellman-Seaver-Morgan Co. The older cranes differ only slightly from these. Open-side main frame, gear drive of the travel wheels, and high travel speed distinguish these machines: trolley travel 250 ft. per minute, crane travel 500 ft. per minute. Steel columns support the outboard track of the 1906 cranes, while the earlier have 12 x 12 timber columns braced by the ship-erection scaffolding.

Figures on the time lost in removing and replacing the outboard track have already been given. The loss of time is reduced greatly at Toledo, where the crane serving a berth of reinforced-concrete construction has its outboard rail supported by an I-beam resting on chairs at a height sufficient to clear the fixed launching ways (see drawing in *Engineering News-Record* of Jan. 2, p. 9). Preparation of the ways, therefore, does not interfere with crane service.

At this yard three 10-ton gantries (Fig. 14) serve the six (short) berths. No speed records have been made here, but the gantries are specially interesting because of the flexibility of service which their design and location afford. They are designed so as to serve not only the berths which they cover, but also the dry docks which at this yard are used as launching slips (see sketch in Fig. 5). A 32½-ft. forward extension out over the dry dock enables the crane trolley to reach nearly to the middle of a ship in the dock. A rear cantilever extension of the same length covers a fabricated-storage and assembly space, and, as the layout of the yard gives a remarkably short straight-line route for material from receipt through the shop and to delivery opposite the ship, conditions for efficient hull construction are present. The travel speed of these cranes, however, is notably slow, being only 100 ft. per minute. A little boom is mounted on the gantry bridge to remove and replace the outboard track.

Two of the three machines were built by the Cleveland

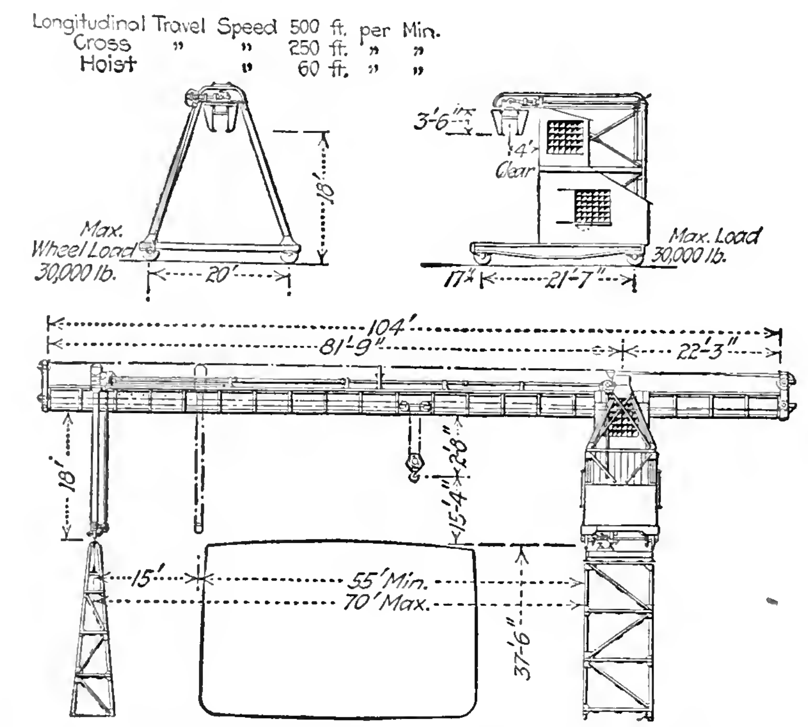

FIG. 13. GANTRY CRANES AT LORAIN EQUIPPED FOR HIGH TRAVEL SPEEDS

Crane and Engineering Co. about 15 years ago, while the third was designed and built by the yard. The spans are 75, 80 and 100 ft.; the long-span crane has no rear cantilever, as it is located close to the side property line, and has the storage and assembly space under the bridge, instead of back of the trestle.

The new Globe Shipbuilding Co. yard at Superior, Wis., has two gantries, which present an interesting difference in outboard rail supports. The first one built, of five tons lifting capacity, has its rail stringer seated directly on the cap timber of the dock wall. The launching ways, which rest on this same cap, cannot be placed until the stringer is removed. When the second crane, of 15 tons, was designed, this difficulty was avoided by raising the outboard track stringer on timber pedestals, about 3 ft. high. The ways can be placed

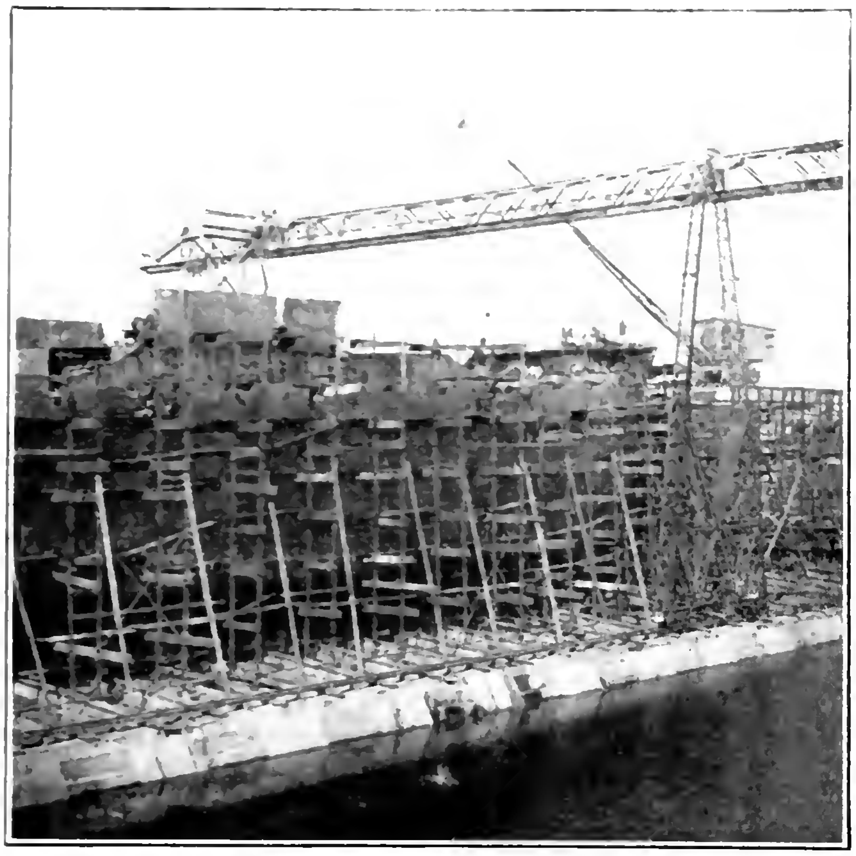

FIG. 14. TOLEDO GANTRY OVERHANGS DRY DOCK USED AS LAUNCHING SLIP

under this stringer between pedestals, and thus the crane can continue in service. James McKellar, general manager of the company, says that it takes about six hours to remove this rail before launching and about one day to replace it. The crane is operated up to within one day of the launch.

Ample width to cover supply tracks, storage and assembly space also distinguishes the newer crane. The first one is located so close to the side of the punch shop that the same arrangement was not practicable, and the inboard track was therefore placed close to the line of the scaffolding (Fig. 15); a cantilever extension of the trolley runway commands a supply track just inshore of the crane track. The new crane (Fig. 16) has a similar cantilever extension in addition to its large gantry width. Both machines were built by the Lakeside Bridge and Steel Co. of North Milwaukee, to outline designs of Mr. McKellar.

Some data of the larger machine are as follows: The span between the track rails is 100 ft., and its cantilever extensions are 18½ ft. and 43 ft. on outboard and inboard ends, respectively. The clearance height is 75 ft., the maximum lift 65 ft. Three speeds of hoisting and lowering are provided for, varying from 60 ft. per minute for a five-ton load to 20 ft. per minute for a 15-ton load. They are controlled from the cab, which, as in the Manitowoc cantilevers, is hung from the trolley, so that the operator has a direct view of his load. Power is supplied as 60-cycle three-phase current at 220 volts pressure. The crane travel drive is actuated by separate motors at the two legs. As the inboard leg carries about 60% of the total load with the trolley at midspan, and also takes all of the wind load, it was equipped with a larger motor; the drive has been found to work well with this arrangement.

Large-Capacity Tower Cranes Introduced This Season—In the pressure to increase crane facilities during the past year, locomotive tower cranes have become the dominant type of crane in some yards. The Wyandotte yard has its six new berths served by Link-Belt tower cranes, while the four old berths are served by the double cantilever crane previously described. One has been installed at Chicago. Ecorse has now four Orton & Steinbrenner tower cranes, against three of its regular cantilevers. Two McMyler-Interstate tower cranes have been added to the four cantilevers at Manitowoc. The McDougall-Duluth Co. yard has a tower crane of distinctive type, the superstructure being of derrick type; that is, only the boom and mast swing, while in the other machines the engine platform with boom is a unit, revolving on a center pin. The Duluth crane was built by the Clyde Iron Works.

One of the new gantry-base locomotive cranes at Ecorse is shown by the view, Fig. 3. It uses the same runway as the cantilever which hitherto served the two berths here. Each of the yard's three cantilevers has been supplemented by a machine of the kind shown, while berths 7 and 8, which are new, have been equipped with a locomotive tower crane alone, a narrow-base machine which will work from storage back of the track instead of between the rails. All four machines have booms 85 ft. long capable of lifting 3½ tons at full reach and 10 tons at 35-ft. reach. They are steam-operated, the boiler being oil-fired. With engines 9 x 10 in., they secure a high hoisting speed—110 ft. per minute with maximum load and 220 ft. per minute on single lines. The swinging speed is four revolutions per minute, and the travel speed 200 ft. per minute. The travel drive is actuated by double-friction clutches on the crankshaft of the hoisting engine. The super-

structure is simply the upper part of a standard locomotive crane of the same manufacturers. The turntable is formed of 28 chilled tread wheels 8 in. in diameter running on an 11-ft. circle of 60-lb. rail.

The Wyandotte cranes are of similar proportions, with boom length of 90 ft. and lifting capacity of about five tons at 50-ft. radius. A slightly more powerful machine

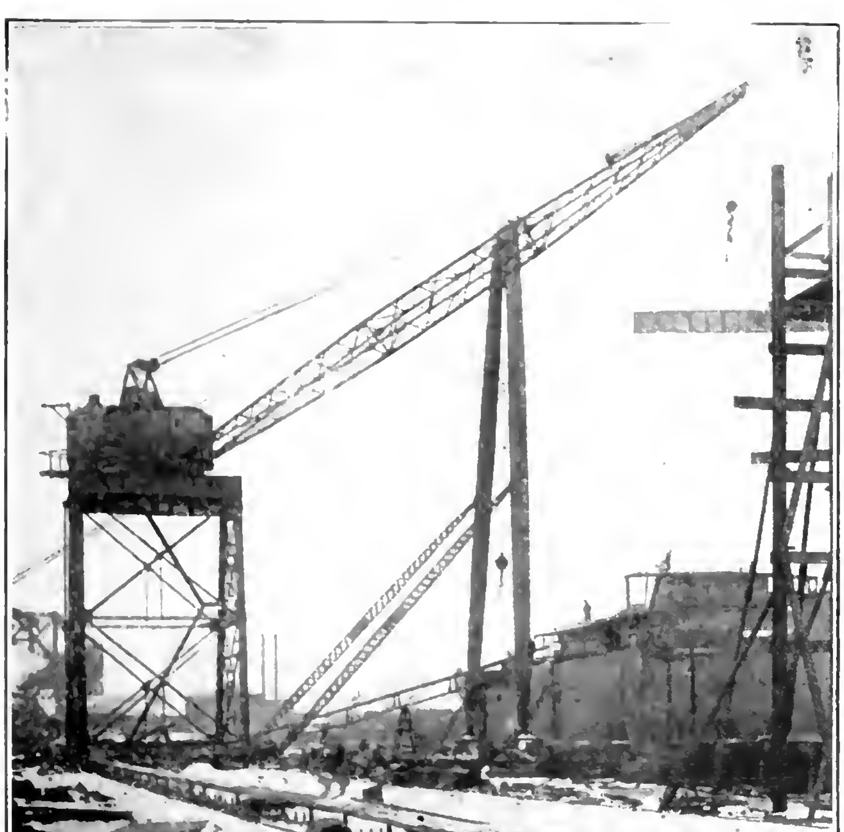

FIG. 17. LOCOMOTIVE TOWER CRANE RECENTLY INSTALLED AT ASHTABULA

has been installed at Manitowoc, and a similar one at Ashtabula (Fig. 17). The boom length of this crane is 98 ft. and the capacity at extreme reach is three tons. All engine parts are set by this crane, working at the fitting-out dock. Boilers do not have to be set at the yard, however, as the affiliated Manitowoc Boiler Works, about a mile away, has a river-front shear-legs for this work.

To carry on shipbuilding at maximum speed, as demanded by the Emergency Fleet Corporation's program, the erection equipment of all the yards, as well as other departments, required expansion. While the existing cranes in most cases were able to handle material fast enough to keep up with the *average* rate of shipbuilding during the past year, irregularities in material supply and fabrication frequently unbalanced the work sufficiently to call for a large excess, temporarily, of erection capacity. The pressure for output therefore led most of the yards to increase their crane equipment to practically double its former amount. All yard extensions made during the year have been provided with one crane per berth, and virtually the whole Lakes district will enter on the 1919 work so equipped.

Chinese, United States and Other Railways

China has 5193 miles of railways, according to a recent commerce report issued by the United States Department of Commerce, giving statistics for 1915. The lines under control of the Ministry of Communications aggregate 3703 miles (including the Hsuchow-Kaifengfu line completed in 1916), of which 150 miles are owned by private companies. Railways operated under concessions to foreign nations total 1490 miles. China has about 460 square miles of territory and 107,000 population per mile of railway, as against 40 and 8600 for India and 12 and 3800 for the United States. The report states that China's extensive system of canals tends to keep the proportion of mileage lower than in other countries. The locomotives on the Chinese government railways total 629, and are of various types introduced by the different nations which have built or provided capital for lines now forming parts of the national system. The necessity for standardization is becoming apparent, as the Chinese policy is to prolong the life of the engines by extensive repairs and renewals, partly on account of the heavy freight charges and agency commissions on imported locomotives. The passenger and freight cars total 1280 and 10,652 respectively. The freight cars averaged 69 tons per ton of capacity, or 69 loads per year, as compared with 99.3 for Japan and 23.7 for the United States. The average haul per ton was 89, 84 and 146 miles for the three countries, respectively. The cost of operation absorbs 53% of the total revenue; while 30% covers interest and other income charges. The remaining 17% is for the Government, of which 10% is the return on investment and 7% is business profit. The total investment is given as about $512,500,000, of which construction and equipment represent about $507,000,000. The total operating revenue for 1915 was $36,000,000.

Road Signs for Amexforce Trucks Save Gasoline

In the Army's Intermediate Section East, in France, It Is Almost Impossible to Take Wrong Route

By Robert K. Tomlin, Jr.
War Correspondent of Engineering News-Record

A CERTAIN adjutant on the staff of an American brigadier general here in France has the reputation of being lightning-quick in detecting mistakes and letting their authors know of them promptly. It is only in exceptional cases, however, that he has been known to praise work. One of these occurred recently after he had finished his first long automobile trip in

Photograph by "Engineering News-Record"

IN FRONT OF HEADQUARTERS SPECIAL SIGN INDICATES BEST ROUTES TO PRINCIPAL TOWNS

the Intermediate Section East. Returning to his general's headquarters he happened to encounter there the major of engineers who is acting as superintendent of roads for this district.

"Are you the man responsible for all those road signs which have been put up in this section?" he inquired. The major admitted that he was. "Well," replied the adjutant, "you've done a damned good job."

The marking of the roads in the Intermediate Section East of the American Expeditionary Forces has been carried out in a manner so thorough that one can now travel from one end of the section to another without once stopping to ask questions and without taking the wrong route. But while the new signs would justify themselves from the point of view of convenience alone, the important feature of this whole business is the enormous saving in gasoline which has been effected by the placing of wooden signboards at frequent intervals along the roads which are now carrying so heavy a volume of Army motor-truck and automobile traffic. Through the Intermediate Section East is moving, day and night, train after train of motor trucks, to say nothing of passenger automobiles, motorcycles and side cars. Gasoline in France today is a costly commodity, and it is imperative to conserve it in every way possible. In this campaign the road signs of the Intermediate Section East are playing a silent but effective part.

The plan of marking the roads embraces other features than the indication of direction. With the long-haul motor-truck trips which have now become so common, as a result of congestion of railway transportation, a train of vehicles may be on the road many days. Gasoline and oil supplies must be replenished en route, and occasionally it is necessary to know where spare parts and extra tires can be obtained. Special signboards are placed to give this much desired information. Then, too, in that part of central France covered by the Intermediate Section East, the old macadam roads were built primarily for slow moving traffic. Curves much sharper than would be considered good practice today are very common. Almost invariably they are built without any superelevation, and with the trees and foliage so general along French roads, one arrives at a sharp turn before realizing it. To prevent accidents at such points, all curves are marked by warning signboards located several hundred feet back from the curve, so as to give the motor-truck driver ample time to slow down.

In July, about 2500 road signs had been placed in the Intermediate Section East. As a general rule, they are squares, 15 in. on a side, and are made of wood salvaged from broken packing cases. They are given three coats of white paint and are lettered in black. When possible these signs are nailed in place, but in cases where they must be affixed to a metal support they are wired. The sign-placing problem, however, is a simple one, and generally it is not necessary to place any post or standard, as all French roads are flanked by trees. Since our Signal Corps has been busy establishing communication by wire between all important Army centers, there are, in addition, lines of telegraph poles to which road signs may be attached. The American Army road signs are recognizable as such because they are always set up with a diagonal vertical instead of like the existing French road signs, which generally have a rectangular form. When an American truck driver sees a white, diamond-shaped sign he knows that its message is for him. There is no confusing our Army's signs with anything else to be seen along a French road.

During a recent trip through central France with the superintendent of roads of the Intermediate Section East I had a good opportunity of observing how the roads have been marked. To begin with, there is in front of headquarters a large rectangular special sign, 4½ ft. long and 2 ft. wide, listing the names of the principal towns and indicating the best routes to them. One of these signs is shown in one of the photographs. On this sign the location of gas stations also is indicated. A driver entirely unfamiliar with the

VARIOUS SCHEMES OF LETTERING FOR ROAD SIGNS USED BY AMERICAN ARMY IN FRANCE

surrounding country can start at this sign and, without questioning anybody, proceed to any town in the section. If his gasoline supply should run low he would know where to replenish it, as a result of the information given on the headquarters signboard.

The matter of getting out of a French village and on to the main road leading somewhere else is no simple matter. The streets twist and turn in the most unexpected manner. A route that looks like a back alley may actually be the connecting link to the *route nationale* for which you are looking. On the other hand, you may, if your French vocabulary has not yet been recruited up to war strength, turn into a street with a name like *Impasse de l'Univers*, only to pull up sharply at its end when you discover that you have been navigating in a blind alley. Another confusing situation is presented to the motor-truck driver by the *place*, or square, which is abundant everywhere. Sometimes half a dozen streets radiate from one of these centers and when you try to choose the right one you begin to realize how overwhelming are the odds against you. I can think of no better way of describing the complex street plan of the small French town than to say that it follows lines that are as regular as those of a dish of Italian spaghetti.

There is one other point about the marking of roads over here which cannot be fully appreciated in the States. Take the case of a motor-truck driver arriving at a cross-roads. He may have two or three choices of route to follow, and all of them may appear to be main roads. Without road signs, what is he to do? The obvious solution would be to stop and inquire at the nearest farmhouse. This sounds simple, but in reality it is not. Many names of French towns as pronounced by the American truck driver mean absolutely nothing to the French peasant. The poor chap whose destination may be, let us say, Pougues-les-Eaux, or Monteignet-Escurolles gets in over his head when he tries to make known orally the name of one of these tongue-twisters. As one driver expressed it recently, after trying out his limited stock of French words on an old farmer whom be encountered plodding along the roadside:

"These guys can't understand you even when you talk to them in their own language."

Direction signs are placed at all crossroads and at intervals along all main routes. They are of several types, as shown in the drawing. If a town happens to be a "gas station" these words are placed in small letters above or below the name of the town. In addition to the direction signs are many others, of which the following are samples:

Road closed to U. S. Motor Vehicles.
U. S. Vehicles Must Not Cross This Bridge.
Bad Curves and Grades—Suitable Only for Passenger Cars and Light Trucks.
Slow! Railroad Crossing—300 Yards.
Loaded Trucks Use This Road.
Slow—Danger—Bad Curve—Sound Horn.

In the case of so long a title as that in the third group above the 15-in. diamond-shaped signboard is too small, and a larger rectangular one is employed generally for these special notices.

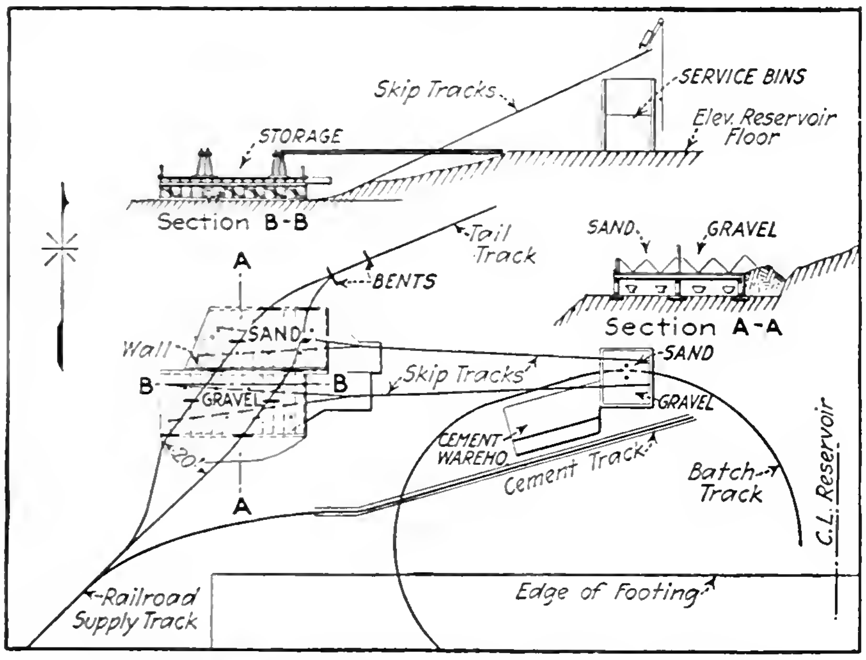
War Wage Increase Met by Revising Construction Plan

Concrete Output Multiplied Sixfold on New St. Paul Reservoir by Changing Method of Operating Traveling Mixing Plant

WELL-PLANNED plant met the handicap of labor scarcity and rising wages, in the construction of the new concrete high-service reservoir for St. Paul, Minn. Transportation was the governing operation. Not far from 150,000 tons of materials, including excavation, had to be moved. For the concrete structure alone 40,000 tons of materials had to be transported some two miles from the railway to the work. At the work these materials had to be assembled into a structure covering 2½ acres. By careful plant selection and layout, material handling both to the site and into the structure was made largely mechanical. Everything was put onto wheels. All raw materials were handled by cars. Concrete when not chuted directly into place was distributed in buggies over runways. The mixing plant was truck-mounted, and even complex forms for groined arches and buttressed walls were shifted by travelers on wheels.



CONCRETE MATERIALS FOR ST. PAUL RESERVOIR HANDLED HUNDRED PER CENT BY CARS

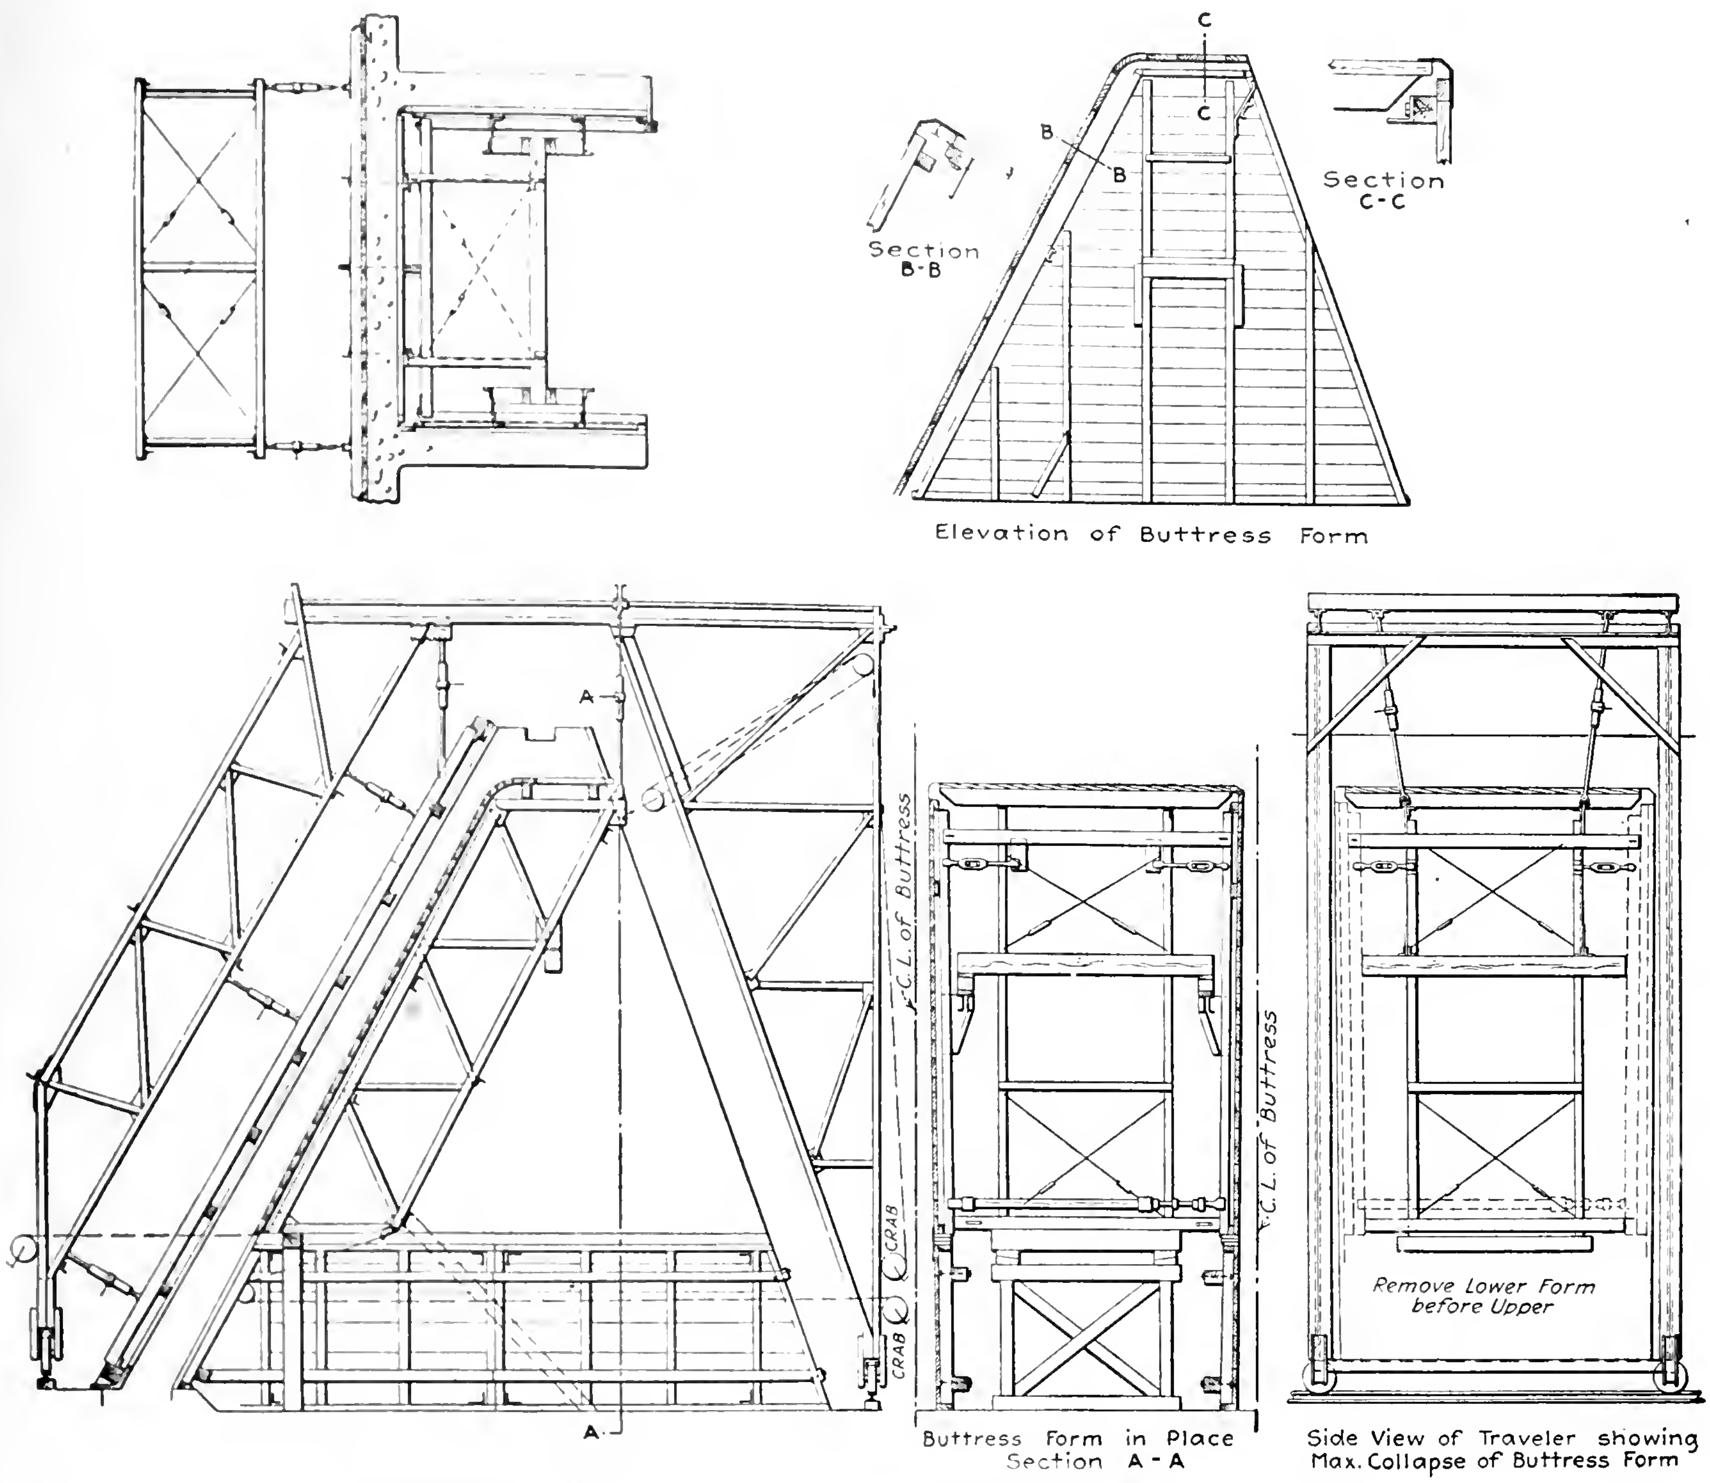
The plans and structural details of the new reservoir were illustrated and described in *Engineering News-Record* of Nov. 15, 1917, p. 927. The plans provided for a structure 452 x 446 ft., so located that a second unit of the same area can be added when required. Structurally, the reservoir consists of an inverted groined arch floor carrying columns which support a groined arch roof. On three sides, the walls are inclined slabs braced by buttresses. The fourth side wall, which will be the dividing wall when the additional unit is built, is a cantilever gravity wall. Included in the main structure are gate chambers, aërator chamber, sluice gates, conduits, valves, etc. The roof and sides are covered and banked with earth.

Located 300 ft. above city datum and two miles from the nearest railway, the reservoir site, despite its proximity to the city, was isolated in respect to available means of transportation. Estimates were made of the cost of tractor haulage. Including a necessary concrete road up the reservoir hill, a figure below $1.20 a ton could not be had. Surveys for a narrow-gage railway connecting with the contractor's yards and gravel plant on the railway two miles away, and passing a clay pit, gave a more reasonable figure, and the railway was built. It was 2¼ miles long, with a 1000-ft. trestle and a maximum grade of 2½ per cent. Turnouts and yard tracks at the reservoir were provided. The road cost $12,000, this figure not including rails and some other materials in stock. This railway, as events proved, did not reduce haulage cost below the original estimate, but it did cut down haulage time. Without it the construction probably would not have been completed in the specified time.

Construction began with the building of the railway and simultaneous excavation of about 90,000 cu.yd. of earth to level the site. Excavation was by steam shovel and narrow-gage cars, wasting the spoil on the sloping sides of the hill. About 32 days were required for these tasks. When the reservoir site had been graded the clay blanket was placed. In this blanket, and later for banking the walls and covering the roof, some 15,000 cu.yd. of clay was required.

All construction materials came in over the narrow-gage railway and was stored as indicated by the sketch map. Incoming tracks ran over the sand and gravel storage bins and to the cement house. From under the sand and gravel bins skip car tracks rose on a 50% grade to sand and gravel service bins with measuring hoppers. Under these bins and alongside the

COMPLEX WALL FORMS ARE MOVED SUCCESSFULLY BY TRAVELER



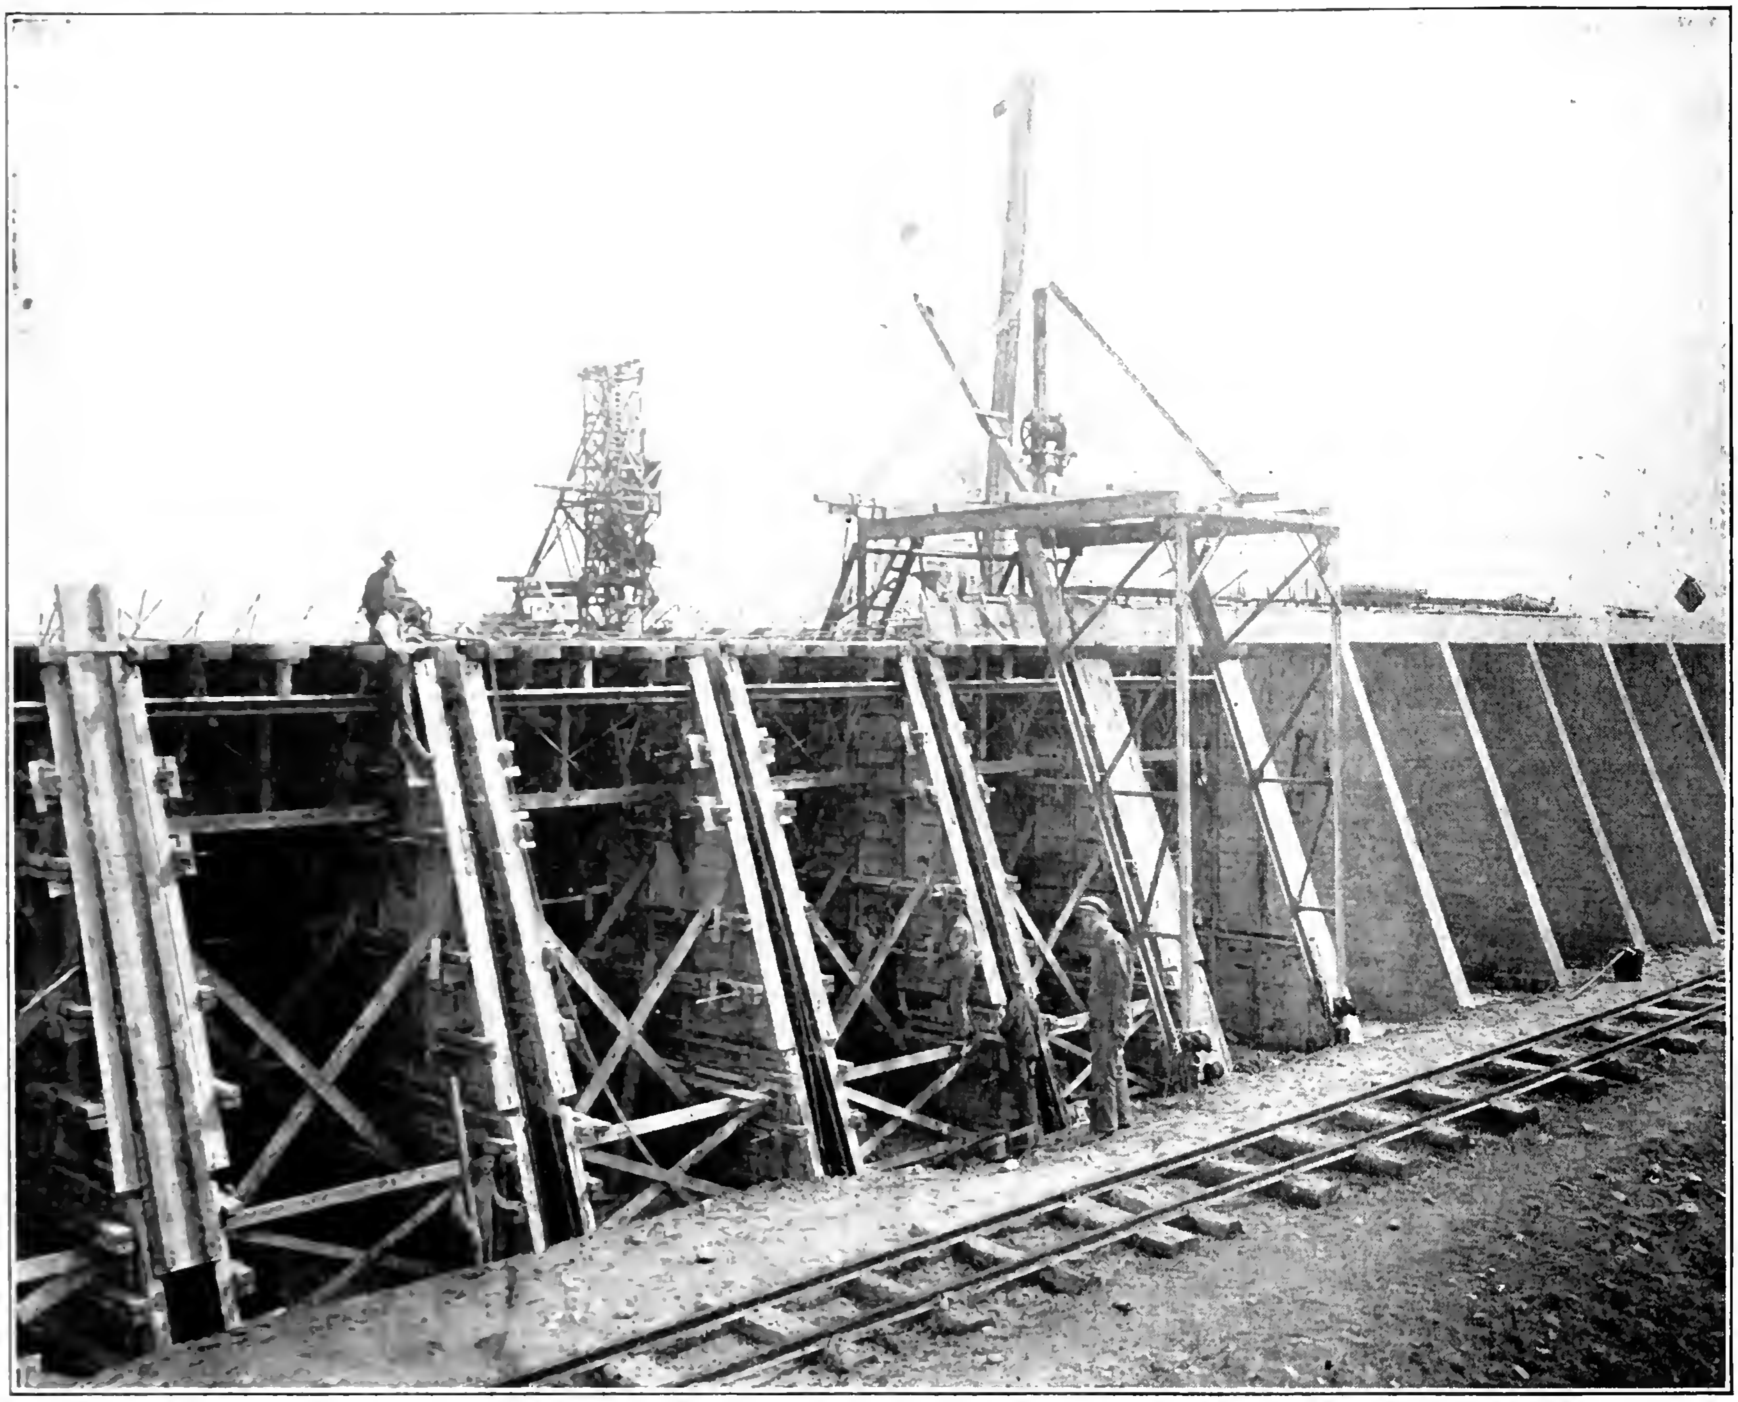
BUTTRESSED WALLS NECESSITATED COMPLEX FORM CONSTRUCTION

cement house ran the batch track to the traveling mixing plant. All batches were proportioned at the service bins and cement house in side dump cars holding each a batch.

Batch cars run to the mixing plant, which was mounted on a 16 x 22-ft. steel frame with a two-wheel truck at each corner and a wheel gage of 15 ft. From the platform rose a hoist tower, with a boom for supporting chutes. The tower bucket was charged from two 1-yd. mixers, which in turn were charged by an elevating skip into which the batch cars dumped. A 50-hp. boiler supplied steam to two hoist engines and to the mixer engines, all mounted on the steel frame.

The concrete was proportioned 1 : 2 : 4. At the beginning, empty batch cars returning from the mixer passed the cement house and there received their supplies of cement. Thence they passed under the service bins and received sand and gravel. With this method of loading, the cement stuck to the car bottom and gave trouble in dumping. To avoid this, a change was made by which the cement was added last. Trouble was then experienced from the cement blowing off the car in transit. The final change was to load first the sand, then the cement and finally the gravel. An inspector controlled the proportioning, from an elevated seat under the service bins. The measuring hoppers at the bins were like those described in *Engineering News-Record* of June 27, 1918, p. 1221. As originally planned, sand and gravel were dropped into the car simultaneously by one lever movement. When the order of loading was changed to sand first, then cement and then gravel, the hoppers had to be operated by separate levers. This was the only change found essential in the plant or the methods of handling raw materials.

The construction of the reservoir structure began with the concreting of the partition wall. First the footing was poured by direct chuting from the mixing plant running on a track parallel to the wall. When the footing was finished the mixing plant retraced its course and poured the wall proper. After the partition wall and a section of the connecting side wall at one end were completed, the mixer track was moved over a distance equal to three bays of the reservoir parallel to its first position. It was planned to complete the reservoir by repetitions of this operation. One condition which prompted this plan was that the specifications restricted chuting of concrete to a distance not exceeding 50 ft. The procedure in concreting



ROOF FORMS COLLAPSED, CARRIED AND ERECTED BY TRAVELERS

the first three bays was about as follows: The inverted groined arch floor three bays wide was poured for several days, by which time the forms for a group of columns had been erected. The mixing plant then backed up and poured the columns. It then moved ahead and resumed pouring the floor until the roof forms were in place on the columns first poured, when it ran back and poured the roof arches and such other columns as were ready. Shuttling ahead and back, the mixer proceeded until three bays across the east end of the reservoir were completed.

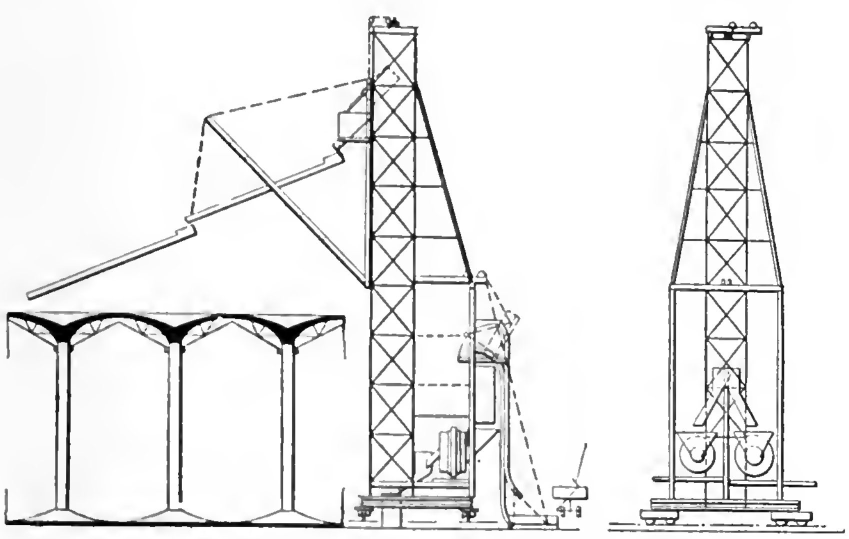
During the operations just described the contractor had been working with the material and labor market rising. A change of plan was necessary to equalize the wage and price increase. While this change was being planned, the mixer was set to concreting the wall footings all around the reservoir, and it had completed this work when cold weather set in.

Too frequent shifts of the traveling mixing plant to place a small yardage of concrete was the fault of the first plan of operation. Not only did the plant have to go ahead and back up several times to concrete the floor, columns and roof for a three-bay zone, but it had to be shifted sidewise, track and all, every 48 ft. During the winter the contractor sought by careful cost analysis a means of overcoming the fault. The outcome was a decision to place a permanent mixer track just west of the north and south middle line of the reservoir, and from this track to complete both halves of the concrete structure, spouting the middle 50-ft. zone and handling the concrete in buggies from mixer to forms for the remainder of the area. This plan was put into operation when work was resumed in the spring.

The procedure by the new plan was to concrete first the east half and then the west half of the reservoir. In detail, the operations were: The mixer, standing at the south end of the north and south track, poured, two rows at a time, nine rows of footings from the track east to the east wall of the reservoir. Concrete was spouted directly into the footings nearest the mixer and was wheeled in buggies on runways to the footing farther away. By the time nine rows of footings had been concreted, column forms had been erected on the two rows first poured. The mixer backed up and poured these two rows of columns, the buggy runways being supported on the column forms. Then the mixer ran ahead and poured two more rows of footings (rows 10 and 11). The form erectors then had ready roof forms on the two rows of columns first poured and also two more rows of column forms. The mixer then backed up and poured two rows of roof arches and two rows

of columns, and ran forward and poured two more rows of footings. These operations were repeated until the east half of the reservoir was concreted. Precisely the same procedure was followed in concreting the west half. By the sequence of operations followed, the concrete poured in each operation had time to set, the form erection was kept ahead of the concrete, and the mixing plant was continuously in operation. The time required to pour 24 footings was six hours; 24 columns three hours, and 24 roof arches 5½ hours. The maximum yardage poured in one day was 330 cubic yards.

The cost of placing concrete by the original method was $1.43 per cubic yard. Then the average yardage of the plant was 25 cu.yd. per day. In 1918 the plant averaged 155 cu.yd. a day. The cost is not available, but it can be stated that it has been considerably less than in 1917, notwithstanding the increased wages.



Sectional Elevation Front Elevation

TRUCK-MOUNTED MIXING PLANT FACILITATED ZONE CONCRETING

When work was started in 1917 wages were on a 25c. per hour basis. In 1918 work began with an increase to 30c., then to 35c. and finally to 40c. Labor difficulties were not lacking. During the height of operations 175 men were required, but a two weeks' payroll had 527 names entered.

Form handling by means of travelers was employed whenever practicable. In building the partition wall timber sections 12 ft. long and the full height of the wall, 21 to 23 ft., were supported and moved by steel frame travelers which straddled the wall. Forms were set up for a 50-ft. wall section at a time, and a 50-ft. section of 150 cu.yd. was poured in six hours. This did not include footing, which was concreted in a separate operation at the rate of 25 cu.yd. per hour, or a 50-ft. section in eight hours. Side walls were concreted in step with the floor, roof and column construction previously described, except the footing slab, which was completed ahead of the other work. Chief interest in the side-wall concreting lies in the use of traveling forms for a complex wall design. The forms and traveler are shown by the drawings and picture. All of the forms were designed with care to economize in lumber by repeated use. Groined arch roof forms were like the wall forms handled by travelers.

The contract for the work was held by the George J. Grant Construction Co., St. Paul, Minn., which completed the concrete work Aug. 5, 1918, and the reservoir Oct. 1. The City of St. Paul furnished f.o.b. cars at the contractor's plant all cement, reinforcing steel, pipe and castings.

Fine Screens and Chlorine Meet Daytona Conditions

Ample Dilution—Chlorine Removes 80% of Bacteria — Imhoff Tanks Elsewhere More Efficient Than Screens at Daytona

By GEORGE W. SIMONS, JR.,
Sanitary Engineer, State Board of Health, Jacksonville, Fla.

PERFORMANCE studies of the Reinsch-Wurl sewage screens installed by the City of Daytona, Fla., in 1916, made by the State Board of Health, show that although the percentage of removal of suspended matter is only 7, yet fine screening, followed by chlorination, gives results at low operating cost which meet local requirements of discharge into the Halifax River. The percentage removal of solids would be higher if pumping and storage did not break up the sewage considerably.

Daytona sewage is almost wholly of domestic origin. Originally strong, it is highly diluted by ground water on its way to the screens. Ejectors at seven stations lift the sewage from half the area of the city over a ridge to the screening, disinfecting and main pumping station within the corporate limits of the city. For efficiency of pump operation, the sewage is stored in 560 ft. of 24-in. trunk sewers and in nearby laterals for some five hours, and is then fed to the screens and at the maximum capacity of the pump in operation at the time. Regulation is effected by passing the sewage through a small slot, the size of which is automatically controlled by a float designed by G. A. Main, superintendent. As the most remote sewer connection is less than 7000 ft. from the sewage-works, the sewage would be comparatively fresh were it not for the storage just mentioned. The septic action, combined with the previous agitation of the ejectors and the subsequent passagé of sewage through the regulating slot, comminutes the original solid matter to such an extent that much of it passes the screen in a finely suspended or colloidal state, as is shown by the analytical data and also by tests with Imhoff conical settling glasses.

The raw sewage, as delivered to the screen, shows

upon evaporation (filter paper, etc., method) an average of 95.7 p.p.m. of suspended solids (800 lb. per 1,000,000 gal.) and 620 p.p.m. of dissolved solids—or 87% of the total solids content appears as dissolved solids or volatile matter. The same sewage showed 15 p.p.m. of nitrogen as free ammonia, 31 parts of total organic nitrogen and 142 parts of chlorine.

Sewage flow for 24 hours on May 23-24, 1917, with 335 house connections, was 280,000 gal., or 835 gal. per connection. Daily totals for Dec. 1-5, 1917, are shown by Table I. The average for these five days was 470,000 gal., or 1030 gal. a day for each of the 456 connections then in use. Some idea of the relative rates of flow during the 24 hours may be got from the records of intermittent pumping given in the table. On Dec. 6-7, when the pump was operated continuously for 24 hours, the maximum daily rate of flow was about 860,000 gal. and the minimum night rate was about 500,000 gal. All these records fall outside the winter tourist season and in comparatively dry weather, although there was rain on Dec. 5-6 and again on Dec. 6-7. The ordinary night flow is apparently ground water, at a rate of 100,000 gal. or more a day. This dilution increases the volume of sewage to be pumped and treated, and it affects the operation of the screen.

The Screen and What it Accomplishes

The sewage screen is of the usual Reinsch-Wurl overhung type, 8 ft. in diameter, with 5/64 x 2-in. tapered rectangular slots. The screen is driven by a belt at a rate of approximately 0.5 r.p.m. The rotating brushes move around the vertical axis of the brush shaft at a speed of 7.5 r.p.m. and revolve around their own axis at a speed of 37.5 r.p.m. The screen is placed in a pit at the pump station, receiving the gravity flow from the trunk sewer.

According to the specifications, "the screen will be required to remove from the sewage all solids sedimentable and nonsedimentable above 0.10 in. in diameter." The screen does this, but for reasons already stated a large part of this suspended matter passes the screen, the average suspended solids content of the screened sewage being 88.6 p.p.m., or 740 lb. per 1000 gal. On Dec. 6, 1917, an increase appeared in the composite samples representing the sewage flow from 5 to 11 p.m., sample collections being made every 15 min. Increases are not of regular occurrence, as decided reductions have also been made, as on Dec. 5, 1917. At this time composite samples representing the flow from 2:55 to 5:15 p.m., collected at 5-min. intervals, indicated a decided reduction.

The removal of screenings is the one real criterion by which to measure screen performance. During the pumping period, 2:55-5:16 p.m. Dec. 5, 3.67 cu.ft. of wet screenings were collected from 195,000 gal. of sewage, representing a removal of 18.8 cu.ft. or approximately 1080 lb. per 1,000,000 gal. From the pumpage started at 11:20 p.m. on Dec. 5 and continuing for 2.5 hours and again resumed at 6 a.m. Dec. 6 and continuing for an hour, 15.3 cu.ft. of wet screenings were collected per 1,000,000 gal. of sewage, representing the night flow. During these two periods a total of 291,000 gal. of sewage were pumped; 208,000 gal. from 11:20 p.m. to 1:50 a.m. following a heavy downpour of rain, and 83,000 gal. between 6 and 7 a.m. The influence of the rainfall can here be noted. The combined removal of wet screenings during the two periods representing the night flow was considerably less than during the period preceding, when there was no rainfall. The reduction of screenings following a heavy rain is made still more apparent in the following paragraph.

TABLE II.—COMPARISON OF SUSPENDED MATTER REMOVED BY IMHOFF TANKS AND R-W SCREENS

Raw Sewage, p.p.m.	Treated Sewage, p.p.m.	Percentage Removal	Place	Method
170.0	48.0	72	Eustis	Tanks
116.0	35.0	70	Mulberry	Tanks
201.0	85.0	58	Tampa	Tanks
95.7	88.6	7	Daytona	Screen

To get results with the screen operating continuously, a 24-hour test was instituted 11:36 a.m., Dec. 6, 1917. All sewage passing the screen was carefully gaged and samples were collected at frequent intervals. During this 24-hour run a heavy rain occurred which affected the flow curve decidedly, and 446,000 gal. of sewage passed the screen. From this total sewage flow only 4.7 cu.ft. of wet screenings were collected, representing about 10 cu.ft. per 1,000,000 gal. These wet screenings weighed 271 lb., or 608 lb. per 1,000,000 gal. of sewage. Unfortunately, no apparatus was available for making moisture determinations of the screenings. The screened sewage showed an average of 88.6 p.p.m. suspended solids, or 740 lb. per 1,000,000 gal. of dry matter.

As the sewage flows upon the screen the degree of comminution is easily noticeable, and the finely divided appearance of the screenings gives additional evidence of the disintegrating action. The sewage after screening is very turbid, high in suspended solids, but free of large particles which would have a tendency to float, despoiling banks and flats, and of a quality suitable for disposal into ample dilution water.

The wet screenings, which average 14.5 cu.ft. (2½ cans) a week are removed from the screen station to a dumping ground a mile west of the city limit by a negro who is paid 37½c. a can for this work.

Chlorination to Protect Oyster Beds

Chlorine is used to protect the oyster beds in the vicinity of the sewer outfall into the Halifax River. When the plant was first started the chlorine was supplied to the sewage, previous to the screening, at a rate of 20 lb. per 1,000,000 gal. of sewage treated. During the spring of 1917 the point of chlorine application was changed so that the greater part of the disinfectant was admitted to the chamber under the screen, a small portion still being admitted to the upper side of the screen. Bacteriological determinations made under the original plan (chlorine applied previous to screening) indicated a 75% reduction of all bacteria and a 90% removal of the colon type. At the present time, with the chlorine cut down to 5 lb. per 1,000,000 gal., there is an 80% removal of all bacteria.

For the year 1917 the cost of screen operation, including labor for removing and burying screenings and for other purposes and slight repairs, but with no allowance for power consumed, was $370. The sterilization cost for the year was $679.

Much has been said of late as to the relative merits of fine-screen and Imhoff-tank treatment. That there is a definite place for screen installations and a future

for fine screens is unquestionable, but screens will hardly replace tank treatment where refined results are necessary. Out of curiosity the writer has collected a few suspended-matter removals from Imhoff tanks in Florida, in plants treating sewage closely resembling that at Daytona. These results are shown in Table II. (See preceding page.)

With the usual Florida conditions—where fresh sewage is to be handled, quantities are small, flow is regular and ample supplies of dilution waters are available—the screen is more to be preferred than the tank because a refined treatment is not essential.

In conducting investigations at Daytona the writer has received heartiest coöperation and assistance from George A. Main, superintendent of the sewerage department.

Characteristics of War-Time Highway Work in Great Britain and the United States

War Conditions Have Been Injurious to Roads in Both Countries, and Immediate Maintenance Is Necessary—Each Has Recognized the Importance of Better Systems, Nationally Organized

This article has been prepared by an engineer who has seen the work of the United States Highway Council at close range and has also been in touch with highway work and highway control in Great Britain. A brief comment on this article will be found in the editorial pages—EDITOR.

NOW that peace is assured, it is apparent that one class of public works in need of immediate attention in this country and Great Britain is the public highway. In both countries it has been subjected to such excessive wear and inadequate maintenance, the investment in roads is already so great that the loss due to further neglect will be a serious economic matter, and it has been demonstrated that the utility of the roads during war times has so national an aspect that there, as well as here, a national system of highways is receiving serious study. Until the war laid its heavy hand on road work, the nationally economic value of main roads was looked upon in many quarters as theoretical rather than actual. The purpose of these notes is to point out how the war has nationalized road work on both sides of the Atlantic among English-speaking peoples.

Pre-War British Road Work

Before the war Great Britain had made a small step toward national roads by the creation of the Road Board. This was formed in 1910 for the purpose of assisting financially desirable improvements in the highways of the United Kingdom. The influence of this board was directed toward the widening of narrow roads, the improvement of road intersections, the strengthening of bridges and the betterment of the pavements forming the roadway. The actual amount of money granted by the board has not been large, but its influence has been marked.

When the war broke out there were 150,000 miles of roads and streets in England and Wales, of which 33,600 miles were in cities and 23,800 miles were main rural highways. The funds for the road work were provided by taxes levied by the local authorities, by loans which required the sanction of the Local Government Board and which were equivalent to American bond issues, and, to a small extent, by funds supplied by the Road Board. The funds supplied by local taxation formed most of the appropriation for road building, and were not directly subject to national control.

In Scotland there were 24,900 miles of roads and streets. Here the financial management is more local, for there is no national board to control the making of loans for road work. The Road Board exercises practically all the national influence there is upon the highways of the kingdom; it is mainly advisory and coöperative.

In Ireland there were 58,300 miles of roads and streets, under a sort of dual control by both county and district councils. Here there is a Local Government Board which must give its consent to all loans for public works, so that the local financing of road work, not carried on by direct taxation, is under central control.

British War-Time Road Control

The financial features of road work in Great Britain during the war have been little understood in the United States, and as a consequence many erroneous statements have been made. It has been frequently stated that the British expenditures for road work have greatly increased; actually, however, the total funds made available for road and street work have remained practically stationary, despite the fact that large appropriations were made by the War Department and other agencies for roads having heavy motor traffic. The local authorities have continued to raise for road work sums which would be ample for their usual programs under normal conditions, but these sums have rarely been used up, and there are considerable accumulations available for work when conditions become normal. Practically no money has been raised for road work by loans, the Local Government Board stopping such bond issues, and the funds of the Road Board have been greatly reduced.

As soon as the war began, British road building received its most severe setback by the call for experienced road engineers and road builders for service in France. Just as some of the British railways had their rolling stock, rails and ties shifted to France almost overnight, so every highway resource in men and materials was sent across the Channel to maintain the roads which it was recognized at once were essential for military success. The first call was by no means the last, and the reports of the local authorities are practically unanimous in declaring that lack of skilled labor at any price has been one of the most serious difficulties in British road work since 1914.

This is a more serious matter in Great Britain than

here, because the normal road program is based on wages for experienced road men which are extremely low from our viewpoint. This is shown by a recent report from the authorities of Derbyshire, complaining that the minimum wages have been advanced to 20s. (about $5.00) a week, and there were 157 workmen receiving 25 to 30s. Even wages so high as to be unprecedented have failed to obtain needed men, and the following quotation from the latest report of the county surveyor of Worcestershire is typical of many such statements: "While there are considerable stocks of material in certain parts of the county, they are more or less concentrated on a few roads on which it was impossible to provide the labor. In some cases the material has been deposited on the side of the road for upwards of three years, and it is unfortunate to be compelled to watch a road seriously deteriorating while material is ready at hand."

A few attempts have been made to work German prisoners on the roads, but the results do not seem to have been satisfactory. The county surveyor of the eastern part of Suffolk recently reported that he had some prisoners on road work being done at the request of the military authorities. They were paid about 1½d. an hour; some were good workers and some were slackers. The results depended to some extent upon the man in charge of them, for they were not obedient to civilian superiors, and more attention had to be paid to their oversight than was the case with free labor.

By the end of 1916 it was apparent that the war demands for stone and gravel were so great that some method of rationing such materials was needed. Accordingly, the Road Stone Control Committee, composed mainly of experienced engineers, was organized to have supervision of their production and transport. It obtained from the local authorities statements of their requirements and from the quarry and pit owners of their facilities for production, also information regarding transportation facilities. Then the material needed for essential war-time road work was allocated, and the remaining needs were met in what seemed to the committee the most fair manner.

Complaints Against Restrictions

There has been some complaint about the restrictions placed upon local officials, but such complaints arise in times of peace as well as under the stress of war. One of the chief complaints has been that the committee forced some authorities to employ local stone, inferior to that previously used and brought from a distance, but the war-time demands for the superior stone and the limited transportation facilities in Great Britain during the war are held to justify such rulings. When the committee first exercised its authority producers of these materials were quite generally able to supply large quantities of them, and there was much criticism that prohibition of shipment was in some cases an unwarranted and arbitrary exercise of power. As time went by, it was discovered that such shipments would have been useless, because the labor for using the materials was not available, and those accumulating in stock were used elsewhere to immediate advantage. In other words, the comprehensive knowledge of the needs of the country which the committee possessed enabled it to foresee conditions better than the local authorities could.

The supply of tar for road work was also curtailed in 1917. In September, the Minister of Munitions directed that no crude or dehydrated tar should be used for the purpose, without a permit. The Explosives Department of the Ministry of Munitions allocated 52,000,000 Imp.gal. for 1918 road work, and entrusted its distribution to the Road Board. This quantity was later reduced to 47,000,000 Imp.gal., and the specifications were changed to allow a somewhat greater percentage of oils in the tar. This material has been used only on roads of national importance. As a matter of fact, the scarcity of labor in some districts has been so great that even had more tar been available it could not have been used satisfactorily. Attempts have been made to use women in tarring roads, but with only fair success.

War-Time Road Work Under Direct Control of Road Board

Strictly war-time road work has been under the control of the Road Board, to which the Army Council early delegated the following duties: (a) Arranging and supervising the construction and maintenance of new roads, and the improvement of certain private roads in several districts for military purposes; (b) arranging with local authorities for improvements on public roads, mainly at the cost of the Army Council, required for military purposes; (c) settlement with the local authorities for the Army Council of damages due to extraordinary traffic for military purposes; (d) similar duties for the Admiralty, the Ministry of Munitions, the Timber Supply Department of the Board of Trade, and for the Air Ministry. About $22,000,000 have been spent on such work since the beginning of the war; about three-fourths of this sum has been spent for the War Department.

The common belief in the United States that the British Government repairs all damage it does to roads, or pays for such repairs, is entirely wrong. The principle on which payment is made can be stated by quoting as follows from a recent report of the county surveyor of Nottinghamshire: "The damage done to the roads by the timber traffic has been considerable. Up to the present no satisfactory scheme has been inaugurated whereby the liability for the damage can be fixed on the responsible parties. Ninety-five per cent. of the timber is for national purposes, but the Treasury has so far declined to accept the responsibility for making good damaged roads, except those damaged by conveying timber on behalf of a direct Government department, it being left for highway authorities to take proceedings on the ground of extraordinary traffic against the person by or in consequence of whose order the traffic has been carried on." As such proceedings are very expensive, the local authorities are reluctant to begin them, for even if they are successful, the cost of obtaining an award will be so great that the net return is likely to be inconsiderable.

On account of the shortage of materials and labor during the war, most of the work done on the roads of Great Britain has been performed on main routes. The

impetus given to reconstruction and effective maintenance by the Road Board for a number of years prior to 1914 put the highways generally in good condition for any ordinary service. The county surveyor of Nottinghamshire reported a few months ago that the main roads under his care were in a very satisfactory condition, considering the general condition of public works.

In Aberdeenshire, where only one-third of the normal number of men can be obtained, the official report for the last fiscal year calls the road conditions very fair. In Essex, the roads have of late been kept in fair condition with the greatest difficulty only. There "efficient labor has been greatly reduced, whilst team labor in the ordinary sense has almost ceased to exist." In Kent and Worcestershire, the main roads have been maintained in fair condition, but they will soon need reconstruction. In Northamptonshire, a recent report states, the shortage of labor and materials has made maintenance very difficult, and extensive reconstruction necessary as soon as possible. In Gloucestershire, the conditions of labor, materials and traffic were such that it has been impracticable even to maintain some of the main roads, and highway conditions there are very poor.

If the occasion demanded, it would be possible to give many similar comments from comparatively recent reports of local engineering officials, regarding the British situation. It is unnecessary to do so, however, for these conditions have been summed up by the Road Board substantially as follows:

There is an urgent demand for the reconstruction of important roads to fit them for modern traffic. When the war is over a great number of motor trucks will be released for business uses. Roads must be built for the legitimate use of such trucks, but it should be stated here that there is the same complaint in Great Britain as in the United States about the reckless use of heavy trucks by military drivers. One county surveyor recently commented bitterly on the "unnecessary damage to road surfaces through the excessive speed at which Army motor lorries are driven, both empty and loaded." Another stated lately that where excessive damage has resulted from military and timber traffic, it has been almost entirely due to driving heavy vehicles in the same tracks without endeavoring to break wheel gage. There are strong indications that while heavy truck traffic will be planned for in Great Britain, the regulation of this traffic will be strict, and the taxpayers will have their investment in roads protected against the needless destruction caused by high speed and careless operation of vehicles.

Many Roads Must Be Reconstructed

It has been estimated by the board that about 15,000 miles of English and Welsh roads must be reconstructed for the traffic they will have to carry shortly. It is out of the question for local authorities to raise the money needed for this work and also for the other public improvements which are essential. The cost is estimated by the board at about $150,000,000. It is justified, the board states, by the fact that unless the main roads referred to are reconstructed to carry heavy traffic, as they become worn out, the annual cost of their repair and maintenance, as now built, will be greater than the total annual cost of suitable highways. This reconstruction of main roads is by no means all of the necessary expense at an early date in order to repair war-time neglect and place the roads in suitable condition for the traffic. About $6,500,000 must be spent on new roads and on widening old highways, and about $35,000,000 must be spent on bridge work in order to make the roads useful for the heavy vehicles which present structures are unable to carry. The total expenditure needed in Scotland is estimated at about $15,000,000. The same need of providing large sums for road improvements does not exist in Ireland, according to the Road Board, because the large volume of heavy traffic which has caused such destruction in Great Britain has not existed in Ireland.

American War-Time Road Work

It will not be possible to give any good summary of the effect of the war on roads in the United States until the state and municipal authorities make public the information concerning the work they would certainly have undertaken if not stopped by one cause or another incident to the war conditions. In a general way, however, anybody who has kept in touch with the road work here and in Great Britain has seen for some time one great similarity—namely, that the local officials agreed that the severe restrictions placed on their activities by the national authorities were marked by an excessive zeal in opposing local improvements. Probably this is perfectly natural, for the persons ordered to check construction in specified lines must inevitably be unpopular with those whose activities are hindered, no matter how carefully they may endeavor to minimize the hardships of the regulations.

The first war-time trouble in road building in this country was due to car shortage, just as it was in Great Britain. The difficulty was much greater here than there, however, because so much more road material is moved by cars here, and our coal situation was so much more acute than that in Great Britain. When the Government Commissioner of Priorities issued his order forbidding the shipment of road materials in open-top cars, except under special conditions, the bottom was knocked out of road work until arrangements were made for hauling such materials when empty cars were moving in the direction of the mines. This was a material help. A little later the demands for fuel oil became so great, and the prospect of still heavier demands was so good, that the Fuel Administration put its ban on the use of bituminous road materials. By this time it was apparent that some step had to be taken to enable important road work to proceed and to distribute the available road materials where most needed and where transportation could be provided. Accordingly, the late L. W. Page, director of the Bureau of Public Roads, suggested the formation of a committee representing all the Government agencies interested in any way in road materials and transportation, for the purpose of unifying all regulatory supervision of road and street construction and maintenance. The Secretary of Agriculture approved this plan and invited the Railroad Administration, the Fuel Administration, the War Industries Board, and the War Department to join with the Department of Agriculture

in the formation of a committee which would practically control road and street work through the control exercised by the departments and agencies named. The United States Highways Council formed in this way later had the coöperation of the Department of Labor and the Capital Issues Committee, and, as a consequence, was able to assist materially in overcoming situations similar to those which had previously led to the drastic orders of the Railroad Administration and the Fuel Administration, to which reference has already been made. If the work of the council has seemed oppressive at times, the conditions prior to its formation should be the criterion and not pre-war conditions.

Coöperation Given by State Highway Departments

The work of the United States Highways Council was only made possible by the coöperation of many of the state highway departments. All requests for materials had to be approved by the highway departments of the states concerned before they were considered by the council. Some of the state departments exercised great care in examining applications, and their recommendations were of the greatest help, it is understood. Even in such cases, however, war-time demands for materials or transportation made it impossible for some of the departments and agencies to furnish the assistance desired, and the applications had to be denied. Other state departments did not have the facilities for making such complete investigations, and as it was physically and financially impracticable for the council to investigate every application through the resources at its command, many of the applications were doubtless delayed seriously by the correspondence necessary to establish the facts.

The outstanding facts concerning the work of the council seem to be these: Before it was established, road construction and maintenance were in a fair way to be stopped. As soon as it was established, the conditions under which road materials and transportation could be furnished were explained, and the state highway departments were not only notified, but were asked to coöperate by passing upon all projects in the light of the conditions outlined by the council. This was in line with the action of the Road Stone Control Committee in Great Britain. In both countries the central authority apparently desired to utilize the knowledge and resources of the local authorities to the utmost. The coöperative idea was carried much farther here than in Great Britain, however, and it is believed that, when the extent of the countries, the mileage of roads and streets and the quantities of materials are taken into account, the results here are at least as good as those in Great Britain.

No data concerning the operations of the council have been given out by that body, but in a general way it is known that of the materials approved by the state highway departments the council was also to supply about 85% of the bituminous materials, over half of the cement, about the same proportion of brick, about three-fourths of the crushed stone and about two-thirds of the gravel. Steel was practically beyond the reach of the council, for the other war committees required all of it for war purposes.

The reasons for declining to furnish materials approved by the state departments have been quite varied. In the Southeastern states the transportation situation has been so difficult that it was necessary, speaking generally, to restrict the quantities of materials brought into that section to a minimum, and to stop all freight movements not essential. The fuel shortage operated to restrict the output of cement and brick below the quantities which the producers were able and willing to supply, if permitted to do so. The threatened shortage in fuel oil made it necessary to exercise, over some grades of bituminous road materials, control which would otherwise have been unnecessary. Transportation difficulties existed in some of the Central states which interfered somewhat, in all probability, with the delivery of materials allocated by the council, although the Railroad Administration did all it could to furnish transportation, for road materials, granted by the council. That body has stated the reasons for its actions in individual cases without any attempt at concealment, but it could not lay down detailed rules governing the allocation of materials, because the conditions varied from time to time and from place to place. All it could do was to give every possible help to essential road projects approved by the state highway departments, at the time these applications were received.

The roads of the country have suffered from lack of maintenance, but that is a chronic condition in the United States. It is open to debate whether maintenance would have been done any better throughout the country, as a whole, if there had been no war conditions. The most serious result has been the ruin of many miles of roads by heavy military trucks, just as in Great Britain. Neither country has produced any effective measure of diminishing such destruction by control of speed and careless driving, and very little attention has been paid to overloading.

Selection of National Highways

In this country, as in Great Britain, the war has shown that some roads are a military necessity—which is synonymous with national necessity. It has shown that where railways are congested and good highways are available the latter are a decided help in moving freight, particularly fast freight. But it is apparent in both countries that the cost of building roads for heavy trucks operated at high speed is so great that no balance sheet of the cost of motor trucking which does not include an item for roadbed—just as the cost sheet of railway transportation includes such an item—is complete, and it may be so incomplete as to be misleading. The experience in this country indicates that one of the most difficult things to define is a "road of national importance," and while there is an evident tendency in both countries toward national highways, the war has done little to help along the determination of those roads whose construction and maintenance are so widely useful that they are plainly of national rather than state importance. The war over there and its influence over here have shown that railways, waterways and highways form a complete transportation system that can only be successfully studied in a broad way, free from economic errors, when studied collectively, before its parts are taken for detailed investigation.

Earthquake Wave-Action in Guatemala

WAVE action of the earthquakes in Guatemala last winter is shown effectively by the effects on an old masonary aqueduct near Guatemala City, according to Lee F. Whitbeck, chief engineer of the International Railways of Central America, who has sent the accompanying view.

He states that at a high arch, illustrated in *Engineering News-Record* of Oct. 3, p. 624, the fallen keystone-shaped block of heavy masonry lies directly under its

WAVE ACTION OF EARTHQUAKE RUPTURES COVERED AQUEDUCT AT REGULAR INTERVALS

former position in the arch, indicating that the wave distance coincided very nearly with the distance between the pillars. Under the wave action the spandrel walls evidently puled apart, allowing the central block of masonry to fall, and then closed. This occurred in a succession of arch spans. The wave distance is clearly marked in the accompanying view of the covered aqueduct, where this action caused the arched roof to "pop out" at regular intervals.

How Soldiers Were Quartered and Fed in the Spruce Production Camps

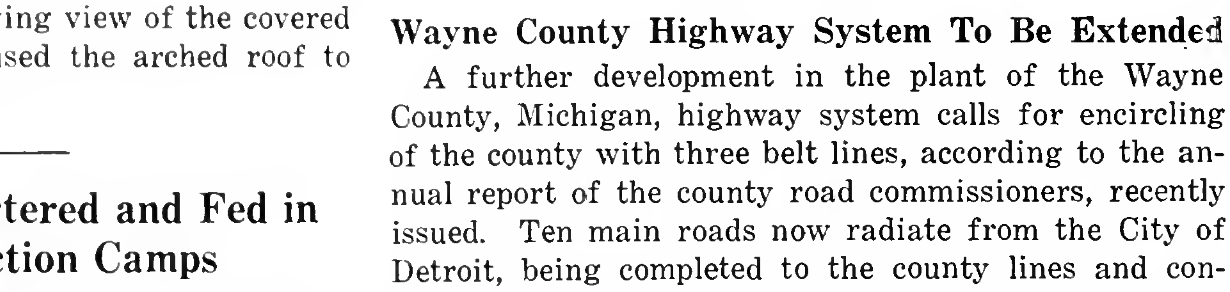
ALTHOUGH there were many phases of the soldier's life in the Northwest woods, under the direction of the Spruce Production Division, which were unlike that at military encampments, yet the camp sanitary regulations were on a strictly military basis and were rigidly enforced. A great contrast to the usual woods camp was presented by the appearance of those camps in which soldier labor was quartered. Typical of these was Camp I-H at Raymond, Wash., the layout of which is shown in the accompanying drawing. The plan shown was the standard arrangement for camps of 100 men. While the men were in fact "under canvas," yet all the tents had wooden floors and wooden wainscoting 3 ft. high, with a wood frame structure over which the tent was stretched. A striking feature of the camp was the scrupulously clean condition of all quarters inside and out, and the strict regulations concerning all sanitary measures. In the mess hall the boards in the table tops and bench seats were loose and were removed and scrubbed daily. Hot and cold water was always available in the bath tent, a feature of the camp that was very popular. The quarters were kept clean and in order by the men themselves. The beds were made, floors swept, clothes hung up, Army shoes shined, blankets aired twice per week, and the sides of tents raised or furled when the weather permitted. The sleeping quarters were inspected daily by both the commander and the doctor of the company.

The regulations of the Food Administration were strictly observed, and meals were served by the contractor on a cost-plus-10% basis. The quality seemed to be very satisfactory to the men. The quantity of foodstuffs and the actual costs of meals served in several of the camps, during August, 1918, are given in the following table:

AMOUNT AND COST OF FOOD SERVED AT THE ARMY LABOR CAMPS OF THE SPRUCE PRODUCTION DIVISION

Camp	Sugar Per 90 Meals (Standard 6 Lb.), Lb.	White Flour Per 90 Meals (Standard 23 Lb.), Lb.	Total Food per Meal (Standard 2.2 Lb.), Lb.	Number of Meals	Cost per Meal
I-A	4.00	7.03	1.404	14,526	$0.24
I-CH	10.76	14.34	2.984	7,690	.485
I-D	6.18	11.88	2.191	8,514	.374
I-E	6.01	11.33	2.047	3,549	.3374
I-F	3.05	14.00	2.086	5,994	.413
I-G	4.03	15.00	1.820	9,642	.339
Averages,	5.67	12.26	2.088	49,915(total)	$0.3647

These figures were supplied by G. W. Gauntlett, district supervisor for the Warren Spruce Co., at Raymond, Wash., in which district these camps were located.



TYPICAL LAYOUT FOR SOLDIER-LABOR CAMP FOR 100 MEN

Wayne County Highway System To Be Extended

A further development in the plant of the Wayne County, Michigan, highway system calls for encircling of the county with three belt lines, according to the annual report of the county road commissioners, recently issued. Ten main roads now radiate from the City of Detroit, being completed to the county lines and connected up to most of the villages and cities. The outer belt will be finished this fall, and a start has been made on both the middle and inner belts. These belts will enable traffic to get out of Detroit on any main road and return by any other main road, as desired.

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

How Raise Status and Pay of Engineers?

Sir—In engineering magazines there is much discussion as to the status and pay of engineers. Not very long ago, while reading a scholarly article along these lines by an engineer of prominence, the writer could not dismiss from his thoughts an experience with the organization of which this same engineer was the chief engineer, in which his indisputable rights received no consideration. This article strengthened the opinion—which had gradually grown to be a conviction—that the average engineer working for a salary has the employer-engineer and those in the higher positions to thank for most of his blessings in the shape of remuneration and resultant standing in the community in which he lives.

The employer-engineer fixes the salary, and to a certain extent controls living conditions. No complaint has ever been heard that he fixes the salary too high, or makes conditions too livable. His main idea seems to be to make low cost records. On large projects no other item contributes so little to the total cost as engineering. Still, in these times, when skilled and unskilled labor is getting two or three times its normal pay, we find some lines of engineering working on practically the same basis as in pre-war times.

Evidently, there will be no relief from this state of affairs until we have an association to look after our own interests. Whether it will be necessary to form a new one or reshape an existing one is the question. Such an association could adopt a minimum scale of salaries for all grades; that is, in civil engineering for rodmen, instrument men, assistant engineers, etc., in the various branches; for city engineers in cities of various sizes, etc., and similarly in other lines of engineering. The engineer or employer who violated this scale could be blacklisted. In a short time the rank and file of engineers, seeing the advantages of such an association, would come into the fold. This may smack too much of unionism to some engineers, but through such an association only, in my opinion, can results be obtained.

Some months ago, in a small city, the seven physicians by mutual agreement doubled all of their fees. Suppose the engineers of that city had done the same, what would have been the result? They probably would have starved, for the services of others from outside could undoubtedly have been obtained at the old rates. Not so with the physicians. Another would not think of coming in and cutting under the new scale established.

Did the physicians' standing in this community suffer? Not that the writer is aware of. The prosperity of a person has much to do with his standing in the community in which he lives. In all probability—other things being equal—the physician with the smallest practice in a big city has a better standing than the city engineer who, acting singly, probably could not get a penny's increase in salary.

These observations are made by an engineer who for twenty years has been of the opinion that hard, earnest work is the all-important thing, and that salary, conditions, etc., will take care of themselves. Twenty years' experience has made him "a sadder but wiser man," and has led him to the conclusion that only through an organization similar to the one suggested above can the rank and file of engineers get results.

SUBSCRIBER.

Sir—"Questioner," in your issue of Dec. 5, p. 1042, states that "following the signing of the armistice he lost a position paying $350 a month." On the same page there is also a letter from V. S. Lawrence on the wage question.

While perhaps but little consolation to these writers, an article in the Sunday papers entitled "Grindstone Jennie," by Christine McKenzie, is *apropos*. The gist of the article is this: Mrs. Hanch is a pretty widow, 24 years old and she has one child. A few months ago she was earning $2 a day as checker in the Submarine Boat Corporation shipyard's (Newark Bay) commissary. She was transferred to a machine shop and her pay jumped from $2 to $8 a day. It took her about two hours to master her new job, earning $48 per week.

This is in striking contrast to $35 a month received by a leveler on a line now owned by the Baltimore & Ohio R.R., with $15 added for board; and $65 a month paid the resident engineers on a line now controlled by the New York Central R.R. Many other instances can be given which would place the engineering profession in very unfavorable light.

I have read Dr. Charles R. Mann's report very carefully, and, in the vernacular of the day, "What's the idea?"—spending years in a college to imbibe knowledge which will yield but a small remuneration, when two hours' practice in a shipyard will bring in $8 per day?

I have been a member of the American Society of Civil Engineers for 30 years, and my membership has never been a financial advantage to me. As you plainly say on page 1057 of your issue of Dec. 12, the main object of engineering societies is "the reading of voluminous papers." I recall one of 350 or more pages that could be compressed into 35. E. N. GINEER.

"No Place."

Proposes National System of Trails

Sir—The pedestrian has been driven from our roads by motor traffic, but, as he is still on earth, he is entitled to some consideration.

The tendency in locating and relocating roads is to take care of a heavy commercial traffic, so that roads begin to assume more and more the utilitarian aspect of the railroads. The problem, even in scenic areas, of locating a road that combines utility and scenery is almost hopeless. It has, however, been done in a few places, such as the Columbia River Highway.

The writer, as the locating engineer for the state highway through the Snoqualmie Pass in 1913 (Cascade Mountains, State of Washington), gave this phase of

the locating problem special study, but with only moderate success; the prettiest places were not touched by the road. Construction of trails through the country and mountains will accomplish this end. These trails should follow certain uniform lines. The right-of-way should be 30 ft. wide. In the matter of grade and curvature, there should be anything up to 10% grades, and curves with a maximum radius of 60 feet.

In the United States, as in all countries, the wealthy have acquired the best places both in the mountains and along the coast, so that an American cannot see his own country except by permission of private property owners. Now, although a man can rightly object to having his estate cut up by a road, he could not make the same objection to the construction of a trail. On the trails, no motor-propelled vehicle or motor cycle should be allowed, and no livestock should be driven over it. The surfaced portion of the trail should be 10 ft. wide—this will enable troops to march in column of squads. These trails would have a great value in the training and maneuvering of infantry, and would be used by the Boy Scouts on their hikes. Trails would run through all the cities and towns.

Every state highway department should have a trail department, so that the work of location, construction and maintenance could be kept separate from that of the roads. It is probable that county engineers would separate their work into road and trail work. By designating a project, for instance as the "Sunset Trail," it would be easy to distinguish between it and the "Sunset Highway," although in naming trails duplication of names should be avoided.

The question of bridges would call for a large variety of treatment. The conditions, as between the mountains and the seashore, would be too variable to permit of the laying down of hard and fast rules. It would add to the military value of a trail situated in a strategic area if all structures were designed to carry a 10-ton road roller.

"See America First" is a good slogan for all Americans, but America cannot be seen until we have built at least 100,000 miles of trails.

Renton, Wash. FRANK W. HARRIS,
Captain, Civil Engineer, United States Army.

Concrete-Base Track For Bridges

Sir—Your editorial of Dec. 12 on concrete-base track and the illustrated article on a 2000-ft. stretch of permanent way of this character on the Northern Pacific R.R., as well as the article on waterproofed floors for railroad crossings over streets, by H. T. Welty, recall testimony given by me in 1917 on behalf of the City of Elizabeth before the Board of Public Utility Commissioners of New Jersey, advocating the use of such concrete-base track for bridges, referring to the low maintenance costs in the subways and elsewhere for such permanent way, and giving also some new designs for concrete bridge floors and other trough sections for ballasted floors.

I introduced here four types of thin floor construction, keeping to about 3 ft. thickness from the underclearance line to the top of the rail (my records are in New York), designed in connection with the problems of eliminating grade crossings on the Central R.R. of New Jersey, where headroom over city streets was very limited, and in new alignment and changes for six tracks of the Pennsylvania Railroad through Elizabeth. The crossing of 12 tracks at two levels over Broad St. made a very interesting problem, one street approach being on sharp curve and at a grade of over 7%, dipping under the intersection of the two railroads to a sinkhole which could not be drained by gravity. The upper railroad was at its summit, with falling grades in both directions.

In making these designs to meet such requirements for thin floors, I began with the old Thompson trough floor which my chief installed on the Park Avenue viaduct in the early nineties, when I was assistant engineer on this work, and followed other practice of record and in evidence within my experience about New York. Mr. Welty has the benefit of all the experience in better designs used on the New York Central R.R. since then, and gives valuable information concerning his several types which may be adapted to the various requirements of the railroad engineer.

In the testimony we brought out at the grade-crossing elimination proceedings to which reference has been made, it was shown that waterproofing materials generally used were not flexible or sufficiently elastic, especially, as Mr. Welty says, at the junction with main girders and attachments of least deflection, and a good type of waterproof thin floor was not in evidence.

Discussion Has Failed to Reach Bottom of Highway-Truck Problem

Sir—In the many discussions of the "motor truck vs. highway" problem that have appeared in print during the past few months, there has been, I believe, an almost unanimous failure to get far enough back into the economics of the proposition. The question that is now vexing highway engineers the country over is, like all other questions, based on certain propositions that have been either firmly established or long recognized as axioms. Starting from these basic propositions, one should be able, by logical steps, to answer beyond the shadow of a doubt two very important questions: First, "Has the motor truck an economic right to exist?" and, second, "Is there a definite relation between the capacity of the truck and the cost of the road and has this relation, in common with other relations, one point that is economically to be preferred?"

Considerable compilation and collaboration will be necessary to answer finally the questions stated above, but the logic that is involved in the answering may be outlined. The questions are of such broad import that there is neither justice nor wisdom in putting the whole thing up to the highway engineer. They are questions for the whole engineering profession to solve, and that solution must be found soon. But let us state the facts that have been overlooked, apparently, in the discussions to date.

As an opening statement on which all can agree, we can reënunciate the old statement—long established but often disregarded through oversight or design—that

"it is the ultimate consumer that pays the bill." This expression has been bandied about until it has become almost if not quite hackneyed, and yet it is deliberately ignored in even the most elaborate estimates of the cost of motor transportation. In the most reliable of the estimates—those based on actual performance—we shall find entering into the ton-mile costs all items relating to the truck itself—interest, depreciation, repairs, taxes, insurance and operation. In how many of them shall we find the fact recognized that money spent on roads for interest, depreciation or repairs should also enter into the estimate? What would happen to the privately owned railroad if it forgot, when fixing its freight rate, to include the cost of building and maintaining its roadbed, bridges and tracks?

When a merchant receives a consignment of goods by freight, he pays for such transportation service a definite amount—an amount which includes the whole cost of bringing the goods to him. This amount he adds to his other costs, in fixing the price to be paid him by the consumer for the goods. If the goods are transported by motor truck instead of by rail, the cost of part of the transportation service—building and maintaining the road, the track on which the truck operates—is not included in the price paid by the consumer for the goods. This cost is paid, however, by the consumer in the shape of a state or Federal tax for highway purposes. Because of our more or less invisible system of taxation, it is impossible to attack the problem from this end—that is, we cannot determine the actual cost to the consumer of any article in which such an item as a road tax enters. The true cost of transporting goods by trucks can be established, however, but before proceeding to outline the procedure let us point out once more that "the consumer pays the bill" either as a higher rate to the railroad or as a tax to the state.

In order to establish the true transportation charge on material carried by trucks, we must include part of the cost of building and maintaining the road. Here begins the argument between the highway builder and the truck manufacturer. What part of this cost shall be included? Opinions, more or less biased, may be uncovered, varying all the way from all to none. A position at either extreme of the discussion is untenable.

Disregarding the truck, roads are still of prime importance and still cost money. It is comparatively a simple matter to determine what a road will cost, both for building and for maintaining, to meet successfully any class or concentration of traffic. It is possible to build a road over which we could transport the Rockies, a mountain at a time, and such a road would be not a question of skill but merely of money. We can therefore determine the difference in cost of building and maintaining a road designed for any class of traffic, and a road designed for any other class of traffic. The calculations may be complicated, but they can be made. With these differences in cost, we are in a position to determine the true transportation charge over a road per ton-mile by trucks of various sizes.

As long as this ton-mile cost is lower than the corresponding freight rate, the truck is an economic factor in life and has a right to consideration, and the truck that would make this figure a minimum is the truck to use, whether its capacity be a hundredweight or a hundred tons. With highways designed for such a truck, it remains for legislation to provide for the proper use of the highways.

It may be objected that the solution is easy to point out but hard to find. That is true, but it is not a problem for one man or for one group of men to solve. We all know the story of the bird that, having found a hole in the roof of a deserted house, tried to fill the house with acorns—how he worked and worked and finally gave it up with the idea that it could not be done. It could have been done, nevertheless, but not by one poor little bird. Just so this proposition calls for the united experience of truck makers and users the country over, even involving the value of different designs in truck construction. It calls for the clearest thought of engineers and financiers and, since it touches the pocket book of every person that pays taxes—and who of us does not?—it is a legitimate subject for Governmental consideration.

W. EARL WELLER,
City Engineer.
Binghamton, N. Y.

Lehigh Valley Dredging Chart Used As Standard for Records

Sir—Referring to the graphic dredging chart shown in your issue of Dec. 12, p. 1070, furnished by G. T. Hand, chief engineer of the Lehigh Valley R.R.: I was allowed to make a few suggestions in this scheme for showing at a glance performances and hold-backs in the work of this suction dredge, operating for the Emergency Fleet Corporation.

Last spring the Fleet Corporation was seriously in need of a third dredge to clean up the turning basin at the Newark Bay shipyard. Partly for patriotic reasons an unnamed 20-in. hydraulic dredge, which we called the "Lehigh," was put to work for the Fleet Corporation on a low flat rental basis. It gave, as partly shown in this chart, an output as high as 970 cu.ft. per hour on a 3200-ft. discharge. This was generally light material, silt, including some shell and hard material.

The work of this dredge was frequently interrupted by the breaking of the line across the Port Newark channel, where we had made an arrangement with the quartermaster's department for quick opening, but in spite of this device the percentage of channel openings ran from 20% to 28% of the total time, increasing costs; notwithstanding this, the clean-up was entirely satisfactory as to cost.

On getting this diagram from Mr. Hand last spring I took the liberty of using it as standard for dredging records in the several shipyards coming under my control.

R. W. CREUZBAUR,
Emergency Fleet Corporation.
Philadelphia, Penn.

Air Currents or Lorelei?

Sir—A queer sort of phenomenon has been occurring at Huntington Lake, the reservoir for the power houses of the Southern California Edison Co., at Big Creek, Cal. This takes the form of a shrill sound which travels, quite regularly, from one end of the lake to the other, very rapidly, and at an altitude of about 200 ft., apparently, above the surface of the water.

Huntington Lake is in the heart of the San Joaquin high Sierras, about 75 miles northeast of Fresno. The lake is about 4½ miles long and one-half to three-quarters of a mile wide, and extends northeast and southwest. The water in the lake is impounded by three large arched concrete dams, the tops of which are at El. 6950 ft. above sea level. These dams were raised from El. 6915 during the summer of 1917.

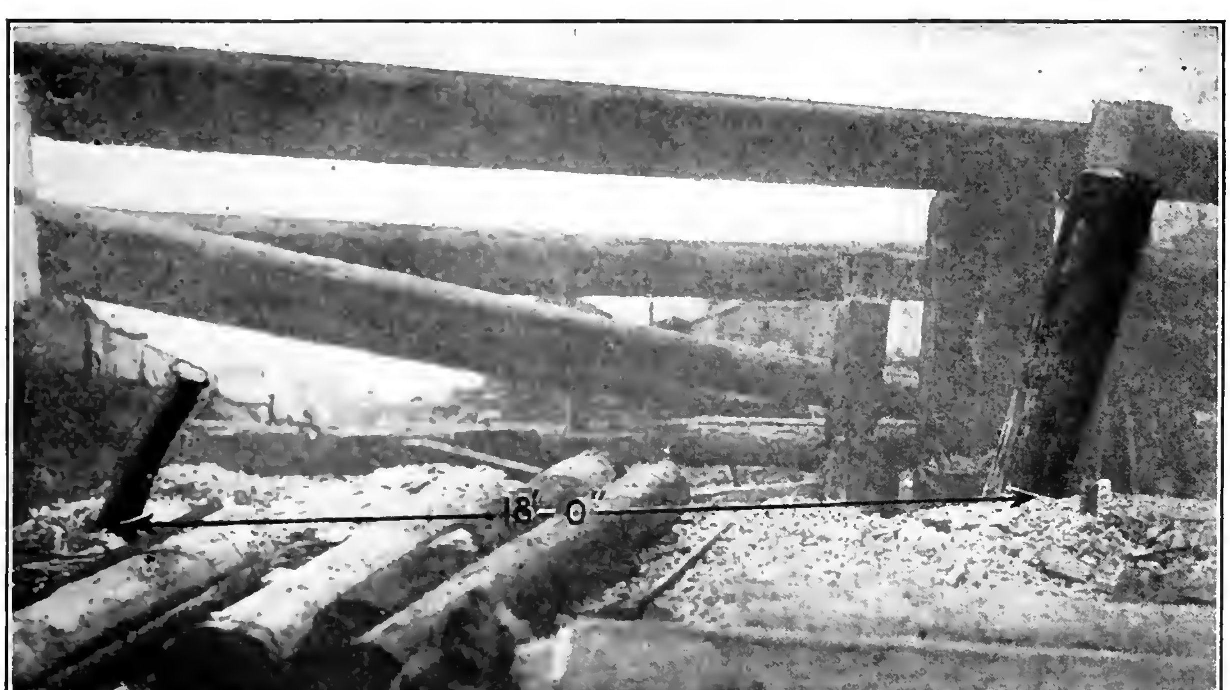
The sound in question was never heard before the spring and summer of the past year, 1918, and it is wondered whether or not the raising of the dams would so affect the action of air currents as to produce a noise which resembles the whir of the propeller of an airplane. The sound occurred regularly during the spring and summer months at 10 a.m. daily, starting in at the south end and traveling to the other end and back in 10 sec. Since the colder weather began in October the visitations have become irregular and less frequent, although they still occur at 10 a.m.

There is no construction work in progress that would produce an echo, and the only explanation advanced so far is that conflicting air currents may produce the sound. Some of the readers of *Engineering News-Record* may be able to corroborate this or offer another explanation. D. H. Redinger.

Big Creek, Cal.

Driven Pile Point Comes Out of Ground

Sir—In driving a wood pile at Pearl Harbor, Hawaii, some time ago, the shaft took a most curious path. As shown in the accompanying view, the point came up vertically through the ground some distance away from where it was driven. At the time the pile was being driven it was noticed that it was not driving straight, but driving was continued, with the result shown.



PILE 52 FEET LONG COMES UP OUT OF GROUND 18 FEET AWAY

The pile was 52 ft. long, of green douglas fir, and it was driven in a hydraulic back-fill of coral, overlying a rock excavation. The distance from the center of the butt, projecting 6 ft. above the ground, to the center of the point, projecting 4 feet, was 18 feet.

James T. Reside.

Washington, D. C.

A Gift and an Appreciation

Sir—One of the most insistent demands to be met by a working engineering library is that for bound volumes of technical periodicals. It has been found that in the library of the Bureau of Yards and Docks the call for previous issues of *Engineering News* and *Engineering Record* is especially urgent. Up to a recent date, the bureau's file was far from complete, and some difficulty was being experienced in obtaining one or two volumes of comparatively late issue.

Henry B. Seaman, who has been connected with the Navy Shipyard Plants section of the bureau during the war period, happened to learn of this situation. Mr. Seaman, who was formerly chief engineer of the New York Public Service Commission, First District, bridge engineer for the Erie R.R., etc., has been a subscriber to the *News* and *Record* during a long professional career and up to a very recent date had kept an unbroken series of the bound volumes on his shelves. It was therefore with every indication of deep chagrin that he informed the writer that, owing to the hazards of moving from place to place, he had found it necessary to consign his entire collection only a week previously to a second-hand dealer in Brooklyn. The writer's regret, as may be imagined, became acute as the tale progressed. Mr. Seaman, however, was not disposed to let the matter rest. He held that the books ought to give the greatest service to the greatest number, regardless of his pecuniary interests in the transaction.

He accordingly got in touch with his dealer, found that the volumes had not been uncrated, and directed that the whole shipment, consisting of three heavy cases, be forwarded to this bureau at once by express, all expenses, save actual rail charges, to be met by him personally. In due time the consignment was delivered to this library, all volumes in good condition, complete with indexes, and excellently bound. Numbers were found to supply the recent deficiencies, and the previous volumes were "tied on" to the bureau's series—so that today, owing principally to Mr. Seaman's generosity, the Bureau of Yards and Docks possesses an unbroken file of *Enginering News* from 1887 to date, and of *Engineering Record* from 1890 to date—a collection practically invaluable for the bureau's purposes.

Over the gentleman's protest, this letter is being written as evidence of the unselfish public spirit and genuine human coöperation which seem to form a salient part of the first-class engineering character.

T. J. Mosley,

Librarian, Bureau of Yards and Docks, Navy Department.

Washington, D. C.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Contentious Contractors Shunned by Engineers

AN OLD contractor who was gossiping away an idle hour with the editor remarked: "One accomplishment which I may claim, and which few contractors can claim, is that in 30 years' contracting I have never had a lawsuit. Sometimes I have lost money by refusing to go to law, but I have gained a more valuable asset, which is the reputation of not being quarrelsome. That reputation has helped me to secure many contracts." Submission is a practice not free from risk. Occasionally, at least, the reputation of being able and willing to hit back is the best guarantee of peace. Nevertheless, it is true that the engineer having contracts to award shuns as one shuns pestilence a contentious contractor. That contractor may have the reputation of doing work quickly and well, of working to specifications in every detail, but, if he is known to be contentious, he is passed by for a contractor who is perhaps less capable but is certainly more amiable. A contractor's appeals to the law courts should be rare, and only when all other resorts have failed. A reputation among engineers of being "easy to work with" is an asset which a contractor should not lightly risk.

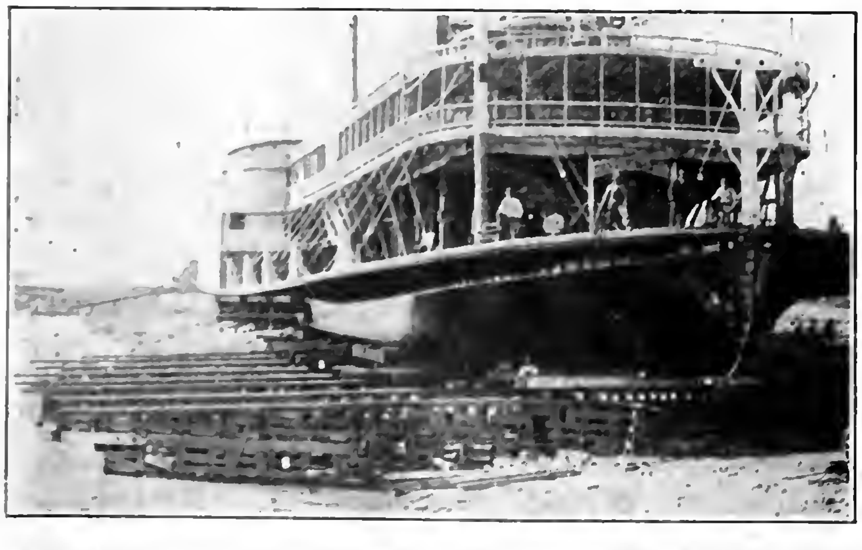
Stranded River Boat Moved and Relaunched on Rollers

By Emil Dauenhauer
Pittsburgh, Penn.

STRANDED by high water 250 ft. from and 30 ft. above the river edge, a 1000-ton steamboat was moved by jacks and rollers and side-launched without injury to any part, and a few days after the launching the boat resumed her regular schedule. Ordinary house-moving procedures were followed, and the operations, begun Aug. 13, were completed Oct. 7, 1918.

As shown by the view, the vessel was a typical steel-hull stern-wheel river steamer. The steel hull had a beam of 40 ft., but 16-ft. guards in the sides increased the overall width to 72 ft. The length was 248 ft., the draft at the stern 3½ ft., and the weight approximately 1000 tons. As stranded, the boat lay parallel to the river.



STRANDED RIVER BOAT MOVED TO RIVER EDGE PREPARATORY TO RELAUNCHING

Using 200 jackscrews, the boat was raised sufficiently to place it on runways consisting of 11 lines of 6 x 8-in. oak timbers laid to a grade of 1 on 12. Skids were placed under the hull, one over each line of runway timbers, and 8-in. wood rollers inserted between the skids and the runways; 225 rollers were used. When mounted, the boat was pulled to the river edge by six sets of block and tackle reaved three and three. At the river edge it was necessary to grade down the bank and carry the runways down to an elevation about 4 ft. above water level. Jackscrews eased the vessel down the steeper grade. From the ends of the runways 11 lines of launching ways were extended down into the water to a depth greater than the draft of the vessel. These launching ways were 13 x 15-in. timbers, thoroughly blocked and braced. The grade was 1¼ on 12. The boat was slid down the launching ways on skids and rollers.

The contractors for the moving and launching were the John Eichleay, Jr., Co., Pittsburgh, Penn. The writer was in charge of the work. The boat was the "Kate Adams," owned by the Memphis, Helena & Rosedale Packet Company.

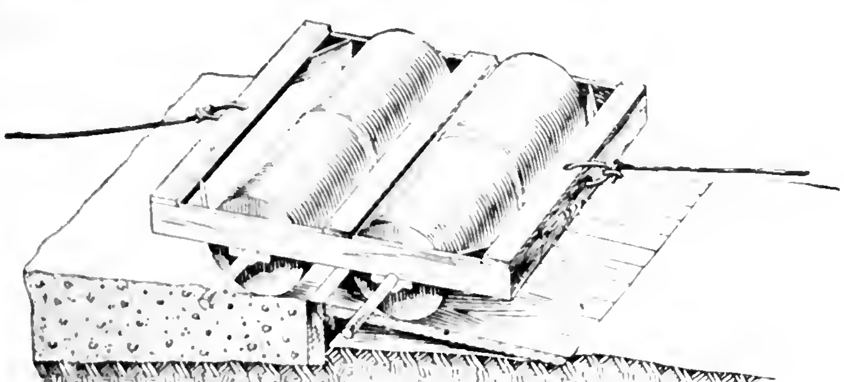
Double Roller and Long Board Float Give Superior Road Finish

By Samuel P. Baird
Columbus, Ohio

EXCEPTIONALLY good finish on a concrete road built at Camp Sherman, Ohio, was secured by using a double roller and long board float. The roller and the float were built on the job.

At Camp Sherman the warehouse street has two 30-ft. pavements separated by a 10-ft. utility space for pipes and poles. The pavements have no crown, but for proper drainage received transverse grades of 6 in. in 70 ft. to 17 in. in 70 ft. The slabs were built in lengths of a day's run, the longest being about 135 ft. The side forms were 2 x 6 in. x 16-ft. Southern pine planks. As the forms were left in place to protect the edge of the slab, their construction was unusual. To insure exact elevation, the side planks were supported on 2 x 4 x 12-in. blocks set 3 ft. apart and tamped to solid bearing in the ground. Thin wedges on the blocks adjusted the plank to exact elevation, and stakes held it upright. To hold the planks close to the slab edge when the stakes were removed, ¼-in. wire ties 3 ft. long were inserted 3 ft. apart along the edge of the slab.

After the concrete had been struck off with an extra heavy strikeboard it was compacted by the double roller shown by the drawing. Four 28 x 18-in. rollers were made of No. 18-gage galvanized iron shaped in a bend-



DOUBLE ROLLER FINISHES CONCRETE PAVEMENT

ing roll. Each roller had a 1$\frac{3}{4}$-in. solid head in each end, made of two $\frac{7}{8}$-in. boards that were placed with the grain crossed.

There were also intermediate heads $\frac{7}{8}$ in. thick. These heads were sawed out on a band-saw. The center hole was a loose fit on a 1-in. pipe. Between the rolls and between the rolls and the frame were placed $\frac{7}{8}$-in. wood washers. The pipe axles were rigid in the frame and extended beyond the frame, for use as convenient handles. All the frame material was $\frac{7}{8}$ in. x 4 in. cypress. When completed the roller weighed 105 pounds.

The location of this work was so restricted by warehouse platforms on one side and a very busy street on the other, that the use of a roller with a handle was out of the question; also, a single roller hauled by ropes did not give satisfaction, so the double roller was designed.

The split feature was the result of an afterthought; we could not find a bending roll to handle anything wider than 28 in., nor could we get the material, No. 18-gage, any wider than the standard sheets.

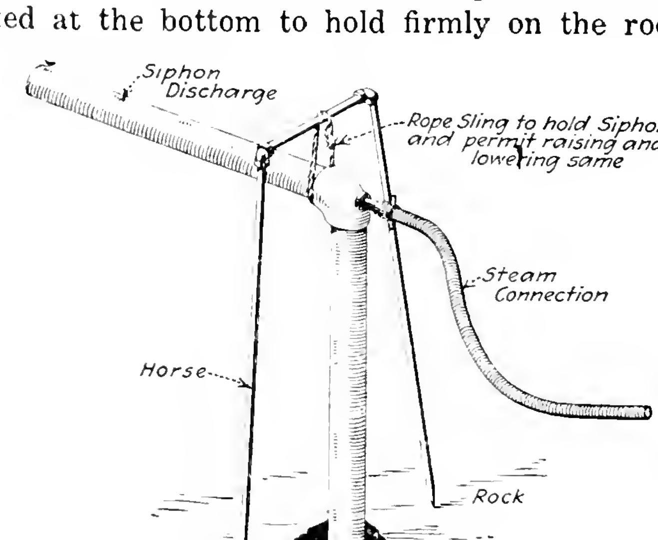
To get best results, there should be placed at each side of the road temporary strips outside the side forms, as shown by the sketch, so that the front roller can be readily pulled over the side forms. In this way any water which is ahead of the second roller can be forced over the forms.

Removal of the water is one of the objects of rolling concrete. Another good result is the crowding down of the coarse aggregate slightly below the surface, thus permitting the ready use of a float 2 ft. longer than the road is wide, and made of some light wood from $\frac{1}{2}$ to $\frac{3}{4}$ in. thick and 8 to 10 in. wide. The results are more satisfactory than those given by a belt. At Camp Sherman the float used was a cypress board $\frac{1}{2}$ x 6 in. and 32 ft. long, composed of two 16-ft. pieces spliced on top. The split-roller idea is of no practical use in my opinion, as the roller—whether pulled by ropes, as in the case in question, or by a handle—is not easily controlled as to direction of movement, and any rolling close to the expansion joints tends to get them more or less out of line.

Simple Horse To Support Steam Siphon

By G. W. McAlpin
Point Pleasant, W. Va.

For holding steam siphons on rock foundations the horse shown in the accompanying sketch has been successfully used. It is made of two pieces of 1$\frac{1}{2}$-in. pipe pointed at the bottom to hold firmly on the rock, and

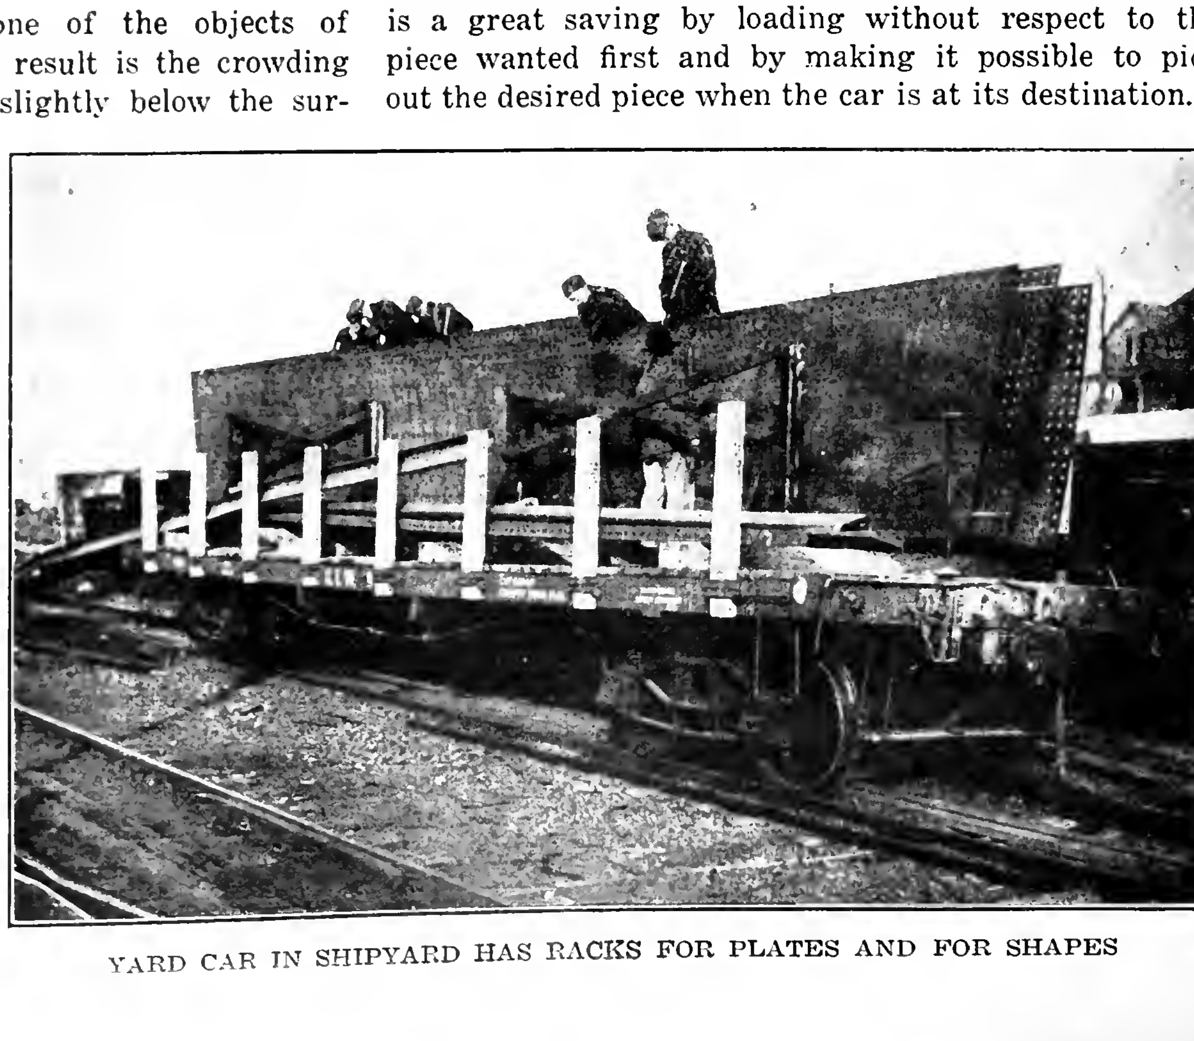


SIMPLE SUPPORT FOR STEAM SIPHON

connected at the top by elbows and an 8-in. nipple. The siphon is suspended between the legs of the horse by a rope passing over the nipple. This permits the raising or the lowering of the siphon, as desired. By resting the discharge pipe of the siphon on a discharge chute, or other convenient rest, balance is obtained.

Shipyard Has Cars With Plate Racks

To facilitate loading and to reduce dangerous overloading, the Groton Iron Works, in the shipyard at Groton, Conn., introduced racks on the yard cars. One such car is shown in the view. This car has plate racks in the middle and shape racks on the side. A greater weight can be carried in this way, and there is a great saving by loading without respect to the piece wanted first and by making it possible to pick out the desired piece when the car is at its destination.



YARD CAR IN SHIPYARD HAS RACKS FOR PLATES AND FOR SHAPES

NEWS OF THE WEEK

New York, January 9, 1919

City Drops 300 Engineers on Half Day's Notice

ew York Rapid-Transit Work Crippled By Cut in Appropriation—Many Contracts Will Be Affected

A New Year's surprise came to over 00 engineers of the Public Service ommission, New York City, in the hape of abrupt discharge from their ositions. The Board of Estimate of he city resolved upon this action at a ieeting held Dec. 30, and advised the 'ublic Service Commission of the acion on the following day. As the iatter involved was the administrative ppropriation for the first quarter of 919, the engineers affected were given otice of the termination of their emloyment on the evening of Dec. 31.

Application made by the commission or the sum of $559,000 for adminisrative expenses during the first quarer was submitted a month ago, but was ot acted upon until Dec. 30. The Board of Estimate cut the amount sked for to $291,000, and required that his amount be expended in accordance vith a schedule of positions prescribed y it. This list, as compared with the xisting organization of the rapid-tranit work, represented a reduction of 76 men (out of 1004), of whom 334 re engineers (out of 812).

Board of Estimate of City Has Final Authority

Prior to the present year, it was ossible for the Public Service Comnission to appeal to the Supreme Court in urgent cases, but under a new aw of 1918 it is considered that final uthority as to all appropriations and ther administrative matters involving ther departments of the city is lodged vith the Board of Estimate. The Pubic Service Commission has therefore pplied to the board for a supplemental ppropriation to restore its staff to roper number.

Sverre Dahm, deputy chief engineer, nd George S. Rice, division engineer, re two of the men whose positions vere abolished by the appropriation chedule. All designing engineers but ne were discharged, and the designing orce cut from about 130 to 41—this n spite of the fact that new contracts re in course of preparation for letting luring the current year, among them hose for the Nassau Street line, the extension of the Steinway tunnel, and new elevated extensions and yards. The vork in hand was sufficient to tax the esources of the designing division as t was organized, and cannot be accomplished in the necessary time by the educed force. In the field, correspondng conditions prevail. In a typical intance, the division engineer and the assistant division engineer are dropped the senior assistant is retained, the section engineer and one inspector and four junior engineers are dropped; this section has lost seven men, out of a staff of eleven. It happens to be one of the sections on which work was being rushed in order to complete the line of which it is a closing link, so as to permit starting of operation of traffic. A number of other sections show similar figures, and in general it is a typical instance of how the situation affects the field work of the commission.

Supervision of field construction is one of the important daily functions of the engineering organization of the Public Service Commission, especially as, under the contract, the commission must furnish all engineering data to the contractors, including lines and grades for all construction. The contractor is dependent wholly on the engineer for field information on the location and the character of the work, for approval of finished work, and for estimates for payment. In work of particular difficulty, as the river tunnels, the engineering service is continuous, and the proper progress of the work essentially dependent upon it. As it will be impossible to perform these varied functions with the depleted staff, the acting chief engineer of the commission, Robert Ridgway, is temporarily making such adjustments and exchanges of men as will permit operations to be carried on in normal manner at the most vital points. The commission's contracts at present include about 20 active sections of rapid-transit lines, exclusive of many contracts for track construction, station finish, equipment, and cases of final estimate.

Engineers Volunteer Services

In order to maintain the organization and allow work to continue, in the anticipation that better counsel will soon prevail and the organization be restored to working condition, a number of the discharged engineers voluntarily continued in their regular duties, giving notice to the commission that this continuance in service is at their own risk, subject to future provision for it by the Board of Estimate, and that the commission is not liable to any claim against it for these voluntary services.

The present crippling of the commission's organization follows a long period of sharp political controversy between members of the commission and officials of the city Government (the commission is a state body, though dependent upon the city authorities for its appropriations and for ap-

(Concluded on page 114)

Commerce Commission For Return of Railroads

Sentiment Favors Return Within 21-Month Period Rather Than Five-Year Control Plan

At the Senate Interstate Commerce Committee's hearing on proposed railroad legislation, Commissioner Edgar E. Clark presented the first alternative yet proposed to Director General McAdoo's plan for a five-year extension of Government control. The Interstate Commerce Commission considers that the 21-month period intervening between the signing of the peace treaty and the return to private ownership affords sufficient opportunity for readjustment before the roads are turned back by the Government. Commissioner Clark said:

"Considering and weighing as best we can all of the arguments for and against the different plans, we are led to the conviction that with the adoption of appropriate provisions and safeguards for regulation under private ownership it would not be wise or best at this time to assume Government ownership or operation of the railways of the country."

He also stated that it seemed obvious that no plan of private ownership should be considered unless it be under broadened, extended and amplified Government regulation. He said that comparatively few contracts for compensation had been perfected between the transportation companies and the Government. Return to private ownership and operation should, therefore, not be understood as meaning precipitous return. A reasonable period of readjustment or preparation should be afforded, and reasonable notice given that upon a given date the properties would be restored to their owners.

Commissioner Woolley dissented from part of the report and gave a number of reasons why he favored the extension plan proposed by Mr. McAdoo, saying that the good accomplished far outweighed the shortcomings and was a promise of better things for the future, and that the proposal to return the railroads to private control had not yet been productive of any concrete plan which would carry the undertaking safely over the breakers obviously ahead.

The commission reiterated its recommendations, made last year, that the Presidential power to merge lines during war or peace should be continued, that railway construction should be limited to works of necessity, and that inland waterways should be developed and coördinated with the railways.

Says France Will Do Her Own Rebuilding

At the meeting of War Service Committee chairmen in New York City, Jan 3, W. H. Manss, until recently chairman of the War Service Executive Committee of the United States Chamber of Commerce, stated that investigations of which he had knowledge had disclosed the fact that France intended to do her own rebuilding. He told the maunfacturers' representatives present that they could not expect much French business in materials. He strongly urged the initiation of an extensive public works program, particularly in highways, emphasizing the point several times. Mr. Manss' words bear out the statements made by *Engineering News-Record* of Jan. 2, that American engineers and contractors—at present, at least—are not wanted in France.

Professional Division U. S. Employment Service Opens Office

The Professional Division of the United States Employment Service has opened a New York office at 16 East 42nd St. Its registrations of experienced professional men are increasing. University graduates in mechanical, electrical, and civil engineering, and in chemistry, and other technical men with several years of practical experience are now registered. The record of each man is carefully investigated before registration is permitted.

Employers seeking men of professional experience are asked to inform the division of the precise nature of the positions which they wish to fill. Only men who are well qualified for such positions are referred to employers.

Zionist Engineers Organize to Rebuild Palestine

The first annual conference of the Zionist Society of Engineers, which was organized at a National Zionist convention in Baltimore in June, 1917, was held Dec. 28-30 in New York City, for the purpose of instituting plans for undertaking engineering development in Palestine, in connection with the expected immigration.

The opening session of the meeting was addressed by Judge Julian Mack, president of the Zionist Organization of America, Jacob de Haas, secretary of the organization, and Dr. Benzion Mossinsohn, director of the Hebrew Secondary School, Jaffa, Palestine. Pledges made by the allied nations with respect to Palestine were reiterated. A resolution was adopted that the society immediately embark upon the preparation of plans and estimates for the agricultural and industrial projects which will be made necessary by the expected immigration. To carry out the resolution, studies of the national resources, topography, etc., of the Holy Land will be made, and a commission will be sent as soon as conditions warrant such a step.

Colonel Roosevelt's Part in Panama Canal and Reclamation Work

Tributes to the Former President by

GENERAL GOETHALS *and* Dr. NEWELL

FOLLOWING receipt of news of the death of Colonel Roosevelt, "Engineering News-Record" asked Maj.-Gen. George W. Goethals, former chief engineer of the Panama Canal, and Dr. F. H. Newell, former director of the United States Reclamation Service, for brief appreciations of the part the former President played in the great works with which they were connected. Their replies follow:

GENERAL GOETHALS—"American engineers especially should honor the memory of Theodore Roosevelt. It was due him that they were given the opportunity to show what American engineering science, skill and initiative could do in the greatest undertaking of peace in the history of the world—namely, the building of the Panama Canal.

"Theodore Roosevelt's name must be forever linked with the building of the canal. He boldly went in opposition to the Board of International Engineers which had decided upon what they believed to be the best type of canal, and whenever and wherever American engineers are gathered they should bear in mind that the confidence that Theodore Roosevelt had in them and in their work gave them the opportunity to serve in linking the nations and in making a highway among them which will forever serve the cause of Humanity and Justice."

DR. NEWELL—"Roosevelt's interest in the irrigation of the arid lands, the preservation and use of the national forests and allied engineering matters of broad national importance was not only deep-seated but effectively shown. That interest came primarily from an enthusiasm for out-of-door things, matured by his experience as a Western frontiersman and student of natural phenomena.

"As Governor of New York he came in contact with the forestry and water supply problems of his state. Almost his first action on arriving in Washington as President was to confer with the experts on these subjects in order to lay out with them his first message to Congress and to develop needed legislation. The resulting Reclamation Act, signed by him June 17, 1902, was made possible by his influence. He gave personal direction to many of the larger reclamation problems, cutting them free from entanglements of red tape and hampering precedents. His guiding principle was that the work, if necessary for the public benefit, should be carried out in spite of opposing precedents unless clearly prevented by existing law.

"We, as engineers, owe a debt of gratitude to Roosevelt not only because of his breadth of vision, embracing in its wide scope the public benefits conferred by engineers, but for his sympathetic attitude and effective co-operation in encouraging and securing methods that lead to economy and efficiency."

Engineers Honor Hoover

Almost coincident with the news that to Herbert C. Hoover has been given the huge responsibility of directing the distribution of food supplies to the neutral and enemy peoples of Europe comes the announcement that American engineers have recognized the great services rendered to humanity by their fellow engineer, by making him the first recipient of the Washington Award.

Two years ago, John W. Alvord of Chicago made a gift of $1000 to the Western Society of Engineers, to establish a prize which is to be given annually to some engineer, "on account of accomplishments which have preëminently promoted the happiness, comfort and well-being of humanity."

©Underwood & Underwood
HERBERT C. HOOVER

The award of this prize is made by a board of 17 engineers, of whom nine are chosen by the Western Society of Engineers and two by each of the four national societies. The award, therefore is representative of the American engineering profession at large.

As Mr. Alvord remarked in his letter giving the fund to establish the award, "almost all engineers serve the public, directly or indirectly, and it is one of the most important duties of engineering societies to point out to their membership and to the public such instances of engineering and administrative skill as seem to have unusual merit, in order that honor may be properly accorded where it is due."

The story of how Mr. Hoover organized the work of feeding the millions of people in Belgium and Northern France during the early years of the war, and how he organized food production and conservation in the United States, is fresh in the memory of everyone.

Now comes a task far surpassing in magnitude and difficulty either of the foregoing; and all agree that upon its accomplishment with some measure of success depends the chances of checking the flood of Bolshevism and anarchy now rolling westward.

Mr. Hoover has been in Europe for several weeks coöperating with the officials of the allied nations in an investigation of European food supplies and needs. On Jan. 3 it was announced at Paris that the allied governments had requested the United States to take a predominating part in the organization of relief measures in all enemy and neutral countries, and that President Wilson had named Mr. Hoover to be director general of the international commission which is to carry on this work. There are 250,000,000 persons with whose food necessities this commission will have to deal.

The story has been told, but will bear retelling, of Mr. Hoover's notable engineering career. That story is of a boy born on an Iowa farm, working his way through Leland Stanford University, being graduated with high honors in 1895 and tackling at once the hard work of mining engineering, first in New Mexico and California and then in West Australia. In his two years spent in the latter country, his rise was so rapid that in 1898 he was made chief engineer of the Chinese Government's Bureau of Mines. The Boxer rebellion of 1900 put an end to this work; and while it was going on he helped organize the defense of Tientsin. When the rebellion was over he found work for a few months in rebuilding Chinese railway and harbor works.

In 1901 he went to London, and as a partner in the firm of Bewick, Moreing & Co., mine operators, he became at once a prominent figure in the organization of mining industry, especially in the East Indies, China and Burmah. The engineering treatises which he somehow found time to write, "Economics of Mining," published in 1906, and "Principles of Mining," published in 1908, are standard textbooks for the profession.

It was characteristic of Hoover that he threw himself in 1914 heart and soul into the work of a hastily organized American committee which undertook the task of rescuing the 100,000 or so Americans who were caught unaware by the war's outbreak and were panic-stricken over the difficulties of getting home.

In the American colony in London, Hoover's great ability and public spirit were so well known that when the huge task of organizing relief for the Belgians was presented the late Ambassador Page was in no doubt where to turn to find a man equal to the need. From that time to the present Mr. Hoover has been been devoting his time and ability to carrying on a work of public service without a precedent in the world's history, and without compensation other than the consciousness of duty that was well performed.

City Drops 300 Engineers

(Concluded from page 112)

proval of contracts and certain other acts). Governor Smith indicated his intention, even prior to taking office on Jan. 1, of reshaping the entire Public Service Commission, and in his message to the legislature recommended division of the functions of construction and regulation, each to be entrusted to a single-headed commission. Under these conditions the action of the Board of Estimate is regarded as merely an item in political warfare, having no regard to the efficiency or services of the engineering organization. No information has been obtainable to show whether the Board of Estimate considered in taking its action the delay and interruption to contract construction work and the probability that contract claims for delay will result therefrom.

War Service Council Approves National Highway Plan

Acting as an industrial advisory council to the War Service Executive Committee of the United States Chamber of Commerce, the chairmen of the War Service Committees at a meeting in New York Jan. 3 adopted a resolution advocating the construction of a national system of highways, the creation of a national highway commission, and the extension of the Federal-aid plan as applied to highways. The resolution was identical with that adopted by the Highway Congress in Chicago in December.

Resolutions favoring a national highway policy were adopted at several of the related-group sessions at the recent Atlantic City Reconstruction Conference, but did not get through the Clearance Committee. The latter body referred them for consideration to the War Service Committee chairmen acting as the Industrial Advisory Council.

Mechanical Engineers Take Over "Engineering Index"

The "Engineering Index," published for 25 years in *Engineering Magazine* and its successor, *Industrial Management*, and the standard index to engineering periodical literature, has been acquired by the American Society of Mechanical Engineers, and hereafter will be compiled and published by the society. The first issue of the index under its new management appears in the January number of the society's *Journal*. The index will be regularly issued in three forms: (1) As a part of the *Journal;* (2) as a separate monthly publication for libraries or individuals desiring to clip the items for indexing purposes; (3) as an annual volume in which all the items for the year are collected.

The "Engineering Index" originated with Professor J. B. Johnson of Washington University, St. Louis, Mo., in 1883, and for 12 years was prepared

under his direction and published by the Association of Engineering Societies. The following classifications give an idea of the scope of the "Engineering Index," as it will be carried in the *Journal:* Mechanical engineering, 31 subheads; electrical engineering, 11 subheads; civil engineering, nine subheads; mining engineering, 14 subheads; metallurgy, seven subheads; aëronautics, 19 subheads; marine engineering, four subheads; organization and management, 13 subheads; industrial technology; railroad engineering, 15 subheads; munitions and military engineering; general science, three subheads.

First Filter Plant Bids Received Since War's End Are Low

Bids received for a filter plant at Wyandotte, Mich., Dec. 30, one of the first municipal jobs of this kind to be advertised for since the armistice was signed, indicate that prices are apparently somewhat lower than those of last spring. For concrete masonry walls, beams and columns, the bids of the six firms represented ranged from $17 to $25. The low bid on filter boxes was $19 a yard. Cast-iron pipe prices ranged from $75 to $90, with specials ranging from $160 to $185. Flanged specials were listed from $185 to $250. The Pitt Construction Co. was the low bidder at $211,235. The figures given were received from R. Winthrop Pratt, civil and sanitary engineer, Cleveland, Ohio.

Angus Sinclair

The death of Angus Sinclair at the advanced age of 78 years removes a notable pioneer in American engineering journalism. It was 35 years ago that he left a job as roundhouse foreman on the Burlington, Cedar Rapids & Northern Ry. and came to New York City to be an assistant editor on the *American Machinist.* His experience previous to that time has been chiefly in the railway field. While holding the job named he managed to attend classes in chemistry at Iowa State University, and was made chemist for the railway company, a job at that time deemed of so little importance, however, that it was combined with the place of roundhouse foreman.

It was at this time that Mr. Sinclair began writing for the technical and railway journals. One of his early writings was a treatise on "Locomotive Running and Management" which has passed through 26 editions.

In 1883 he came to New York to take up work on the editorial staff of the *American Machinist.* A few years later the late John A. Hill also left a locomotive on a Western railway to go to the same journal, and the two men formed a friendship which resulted in a business partnership for the publication of a journal devoted to locomotive engineering. This made a rapid and spectacular success, which in a few years enabled the partners to purchase the *American Machinist,* on the staff of which they had started their work in journalism.

It was then decided to dissolve the partnership and Mr. Sinclair took the journal with whose field he was personally familiar.

He was a member of the American Railway Master Mechanics' Association for 46 years. He served as its secretary from 1887 to 1896, and was its treasurer from 1900 until his death. In 1908 Purdue University conferred on him the degree of Doctor of Engineering.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN SOCIETY OF CIVIL ENGINEERS; 29 West 39th St., New York City; Jan. 15-16, New York.

AMERICAN WOOD PRESERVERS' ASSOCIATION; F. J. Angier, Mt. Royal Station, Baltimore, Md.; Jan. 28-29, St. Louis.

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

NATIONAL RIVERS AND HARBORS CONGRESS; 824 Colorado Bldg., Washington, D. C.; Feb. 5-7, Washington, D. C.

AMERICAN INSTITUTE OF MINING ENGINEERS; 29 West 39th St., New York City; Feb. 17-20, New York.

The following state societies will hold their annual meetings as listed below:

Ohio Engineering Society, Columbus, Jan. 14-16.

Michigan Engineering Society, Flint, Jan. 21-23.

Indiana Engineering Society, Indianapolis, Jan. 23-25.

Illinois Society of Engineers, Bloomington, Jan. 29-30.

Minnesota Surveyors and Engineers' Society, St. Paul, Feb. 12-14.

Iowa Engineering Society, Muscatine, Feb. 19-20.

Engineering Society of Wisconsin, Madison, Feb. 21-22.

The Engineers' Club of Philadelphia will be addressed by Col. James B. Curtis, president of the American Manganese Bronze Co., on "The Legal Engineer," at the weekly luncheon Jan. 14.

The Duluth Engineers' Club, at a meeting Dec. 23 passed a resolution favoring immediate efforts toward the organization of the engineering profession in an effective form to render full public service and to obtain adequate recognition of the work of its members. A committee of five, to be appointed by the president, W. G. Swart, will communicate with other engineering organizations, in order to obtain coöperation and concerted action for calling a general engineering congress, in the name of and by the authority of all the coöperating societies. The Duluth committee will make a report of progress every two weeks. Another resolution relative to the street railways of Duluth was adopted; it suggested that a thorough engineering investigation be made and a plan prepared to provide additional trackage in the center of the city, to relieve present congestion.

The Boston Society of Civil Engineers has made the following nominations for office, through the nominating committee: For president, Leonard Metcalf; for vice-president, Robert Spurr Weston; for secretary, S. Everett Tinkham; for treasurer, Frank O. Whitney. The election will take place Mar. 19.

The Chicago Chapter of the American Association of Engineers was addressed Jan. 3 by Capt. Charles E. Merriam, on "Italy's Part in the War." Captain Merriam, who is a candidate for mayor, represented the Committee on Public Information in Italy.

The Brooklyn Engineers' Club will be addressed tonight by James C. Meem on "Metropolitan Subway Construction." Mr. Meem's paper will deal with the diversion of sewers during construction, the underpinning of buildings and overhead structures, provision for the care of surface structures, the excavation and disposal of material, and methods of tunneling.

The Rochester Engineering Society, Rochester, N. Y., was addressed Jan. 6 by Prof. Victor J. Chamber, University of Rochester, on "The Development of a Research; Synthetic Indigo." The regular monthly meeting of the society will be held tomorrow; C. E. Drayer, secretary of the American Association of Engineers, will read a paper on "Local and National Societies Coördinated."

The Technology Club of Syracuse, N. Y., will be addressed Jan. 13 by Secretary of Commerce William C. Redfield and Dr. S. W. Stratton, director of the United States Bureau of Standards. Secretary Redfield will speak on the various phases of the work of his department, with perticular reference to the Government's reconstruction plans for industry and the extension of foreign commerce. Dr. Stratton is expected to discuss important chemical discoveries not made public heretofore.

The Engineers' Subdivision of the Chicago Association of Commerce was addressed Dec. 30 by George Bayard Jones, who explained the recent report on the proposed rebuilding of various Federal buildings in Washington. He advanced arguments for the removal of the capital to a more central location. T. E. Tallmadge described a layout prepared for a model capital on Lake Michigan, north of Chicago. A committee to follow up the project was named.

Personal Notes

Readers who are returning to civil life from military, naval or other Government service are strongly urged to send in items about themselves and about their friends who are in similar situation. Items should give former position, describe character of military or other service and state the civil work to which the engineer or contractor in question is going. In the case of those with service abroad, information regarding the activities of the units to which they were assigned is especially desired.

HENRY W. CLAUSEN, first assistant city engineer of Chicago, and formerly engineer of water-works construction, has resigned to enter the glove manufacturing business. Mr. Clausen's chief work in Chicago was the construction by force-account of the Wilson Ave. water-works tunnel, intake and Mayfair pumping station.

J. HAROLD RAPP and John J. Dunkel have become associated as the firm of Rapp & Dunkel, structural engineers, Fulton Building, Pittsburgh, Penn.

HOWARD B. KEASBEY has been appointed county engineer of Salem County, New Jersey.

H. STRINGFELLOW, district engineer, Southern Ry., with headquarters at Lexington, Ky., has been appointed district engineer at Charlotte, N. C., succeeding F. Furlow, appointed engineer of surveys, with headquarters in Washington, D. C., as noted elsewhere.

C. R. SEABROOK, who until last September was structural engineer, Chile Exploration Co., Chuquicamata, Chile, has become structural engineer for H. M. Lane Co., industrial engineers, Detroit. More recently he has been engaged in the Air Nitrates Division of the Ordnance Department.

H. Z. OSBORNE, JR., has resigned from the office of engineer of the Los Angeles street planning department to become chief engineer, board of public utilities. Mr. Osborne has been connected with the Los Angeles city engineer's office for 22 years. Last year he was elected president of the Engineers and Architects' Association of Southern California.

F. FURLOW, district engineer, Southern Ry., at Charlotte, N. C., has been appointed engineer of surveys, Southern Ry. Lines and Associated Railroads, with headquarters in Washington, D. C.

MAJ. H. W. LOCKETT, U. S. A., has obtained his discharge from the service and will become associated with Fred. S. James & Co., to take charge of engineering and inspection work. For the past year and a half Major Lockett has served as a building section chief in the Construction Division. Previously he was with the Chicago office of Fred S. James & Co. for 18 years.

IRA E. TAYLOR, previously county engineer, Pottawatomie County, Kansas, has been appointed assistant engineer, extension division, Kansas State Agricultural College, and will specialize in farm drainage.

FRANKLIN D. HOWELL, formerly chief engineer of the Board of Public Utilities, Los Angeles, Cal., has become general manager of the California Highway Transportation Company.

LIEUT. COL. EDWARD BARTOW, Sanitary Corps, U. S. A., was incorrectly mentioned in these columns Dec. 26 as Maj. Edward Bostow, due to a typographical error. He was in charge of water analysis laboratories for the American Expeditionary Forces, and has recently been promoted to the rank of lieutenant colonel. He was formerly director of the Illinois Water Survey.

KARL R. KENNISON, supervising plant engineer, Emergency Fleet Corporation, stationed at the recently completed concrete shipyard in Mobile, has been transferred to the office of the district plant engineer, Middle Atlantic District, Baltimore.

MAJ. CHARLES H. HIGGINS, Ordnance Department, U. S. A., has received his discharge from the service and returned to the firm of Delano & Aldrich and Charles H. Higgins, architects and engineers, New York City.

A. YAPPEN has been appointed assistant engineer in charge of bridge maintenance, inspection and operation, Chicago, Milwaukee & St. Paul Ry., succeeding C. N. Bainbridge, promoted to be engineer of design, as mentioned in *Engineering News-Record* of Dec. 12, p. 1102.

J. C. HILL has been appointed division engineer, St. Louis District, Missouri, Kansas & Texas Lines, with office at Sedalia, Mo., succeeding B. E. Wilbur, resigned.

CAPT. ARTHUR C. POOLE, Corps of Engineers, U. S. A., has returned from Camp A. A. Humphreys to his duties as city engineer of Rochester, N. Y.

L. S. HULBURD, senior assistant engineer, New York State Barge Canal, has been appointed division engineer of the western division of the canal, succeeding F. P. Williams, appointed special deputy state engineer, as mentioned in *Engineering News-Record* of Dec. 26, p. 1203.

W. L. WINTERS has withdrawn from the firm of Winters & Dove, civil and hydraulic engineers, Forth Smith, Ark., and is engaged in practice under his own name in the Merchants' National Bank Building, Fort Smith.

Obituary

DR. ROSSITER W. RAYMOND, mining engineer and author, previously editor of *Engineering and Mining Journal*, published by the McGraw-Hill Co., Inc., died at his home in Brooklyn, N. Y., Dec. 31, at the age of 78. He was graduated from the Polytechnic Institute of Brooklyn, and later studied at the University of Heidelberg, the Royal Polytechnic School, Munich, and the Saxon Mining Academy of Freiburg. He served in the Union Army from 1861 to 1864, after which he began practice as a mining engineer and metallurgist. Four years later he was appointed United States Commissioner of Mining Statistics, and in 1870 became lecturer on economic geology at Lafayette College. He was one of the United States commissioners to the Vienna World's Fair in 1873. He was appointed New York State commissioner of electrical subways for Brooklyn in 1885. For many years, beginning in 1866, Dr. Raymond was editor of the *American Journal of Mining*, which afterwards became the *Engineering and Mining Journal*.

WILLIAM J. GALBRAITH, civil engineer, Montreal, Canada, died in that city Dec. 21. He was 32 years of age, and was graduated from McGill University in 1909. A year afterward he became associated with the Geological Survey in the Rocky Mountains. Later he entered the firm of M. P. & J. T. Davis as assistant engineer on caisson work for the Quebec bridge. Recently he became associated with the Foundation Co. of New York City as a superintendent of construction of shipways on the North Pacific Coast. He was a member of the British Institute of Civil Engineers.

CAPT. GRANDVILLE REYNARD JONES, Sanitary Corps, U. S. A., previously associate professor of civil engineering, Johns Hopkins University, Baltimore, died of influenza at Camp Benning, Columbus, Ga., Dec. 22. Captain Jones was graduated from Ohio State University in 1904 and from the Massachusetts Institute of Technology in sanitary engineering in 1907. His principal professional work was with the filtration plant, Washington, D. C. At Johns Hopkins University he designed and built the Hydraulic Laboratory and the Laboratory of Sanitary Research. He developed several courses in sanitary engineering for the senior classes in civil engineering at Johns Hopkins. Early in November of last year Professor Jones was commissioned in the Sanitary Corps, with the rank of captain, and was ordered to Camp Greenleaf, Georgia, for a brief period of training, at the end of which he was sent to Camp Benning as camp sanitary engineer.

Last Year's Coal Production More Than in 1917 by 36,000,000 Tons

Although the year 1917 was in itself a record year in bituminous coal production, that of 1918 exceeded this by 36,000,000 tons, according to official figures of the United States Geological Survey. The total production for the year just closed was almost 600,000,000 tons. This record was made under the spur of war-time necessity, with fewer men generally in the coal mines of the country than during 1917. Patriotism, increased efficiency, and the desire of the employees to support to the utmost, the Government in its various undertakings, and a better railroad car supply and movement are believed to be chiefly responsible for this increase in production. It is believed that the country at present has a sufficient bituminous coal supply to meet its requirements.

Gage of Argentine Railroads

The gage of the Argentine railways, as given on p. 1204 of the Dec. 26 issue of *Engineering News-Record*, should have been 5½ ft. for the first, 4 ft. 8½ in. for the second, and 3 ft. 3⅜ in. for the third, instead of 6 ft. 5 in., 4 ft. 9½ in., and 3 ft. 4 in., respectively.

Labor Ample, But Materials Still High in Central West

A report from the Central West indicates that an ample labor supply has become available within the past few days. All big munition plants have ended their war work, and employers of labor report more applications than they can handle. A contracting company having large drainage projects on hand in all sections from Minnesota to Louisiana reports a plentiful supply. This company suspended all operations last September on account of labor shortage, but is now going ahead with everything and even starting new projects. Another contracting company which specialized in cantonment and war plants reports labor plentiful at 40c. an hour in all cities where it is operating, whereas 10 weeks ago it could not get labor at 65c. No further shortage is anticipated, the company says.

Regardless of the disappearance of labor difficulties, however, building construction is still delayed on account of the high cost of materials, as was shown in recent bids for steel work.

A bid of almost $120 a ton on structural steel to be used in a proposed building in Chicago indicates that the steel price is still high, especially since this same class of work was quoted two years ago at half that amount. It is reported that architects who have work on hand are recommending that owners hold off until a price of $80 is allowed, and a report is current that a reduction will be made about Mar. 1.

Crushed Stone in 1917 Half the Total Stone Quarried

Crushed stone represented 48% of the quantity and 35% of the value of all the stone quarried in the United States in 1917, according to a bulletin of the United States Geological Survey. The total sales of crushed stone in the United States in 1917 amounted to over 40,000,000 short tons, valued at about $29,000,000, and the average value per short ton at the crusher was 72c., 11c. more than in 1916. Of the crushed stone produced, 66% was limestone, 20% traprock, nearly 8% granite, nearly 4% sandstone and a little over 2% miscellaneous rock, classed as trap.

New Machinery Association to Be Formed

Manufacturers of material-handling machinery will form an association similar to other national associations of manufacturers. Representatives will meet at the Hotel McAlpin in New York City Jan. 15 to hear a report of the temporary committee appointed last fall to consider the matter.

It is expected that the association will afford means for the coöperation of all manufacturers of material-handling machinery with the United States Shipping Board, the Port and Harbor Commission, the Railroad Commission, and other boards interested in the handling of material; also to extend the acquaintance and coöperation of manufacturers. It will also afford means for the concentration in a general bureau of statistical information, to cover the present methods of mechanical handling as now practiced in this country and abroad, the dissemination among the members of information collected and developed by the association, as well as educational campaigns and the collection of information on foreign trade.

A luncheon is announced at which the Hon. William C. Redfield, secretary of commerce, and Edward F. Carry, chairman of the Port and Harbor Facilities Commission of the United States Shipping Board, will speak. The announcement requests all manufacturers of material-handling machinery who desire to join the proposed association to sign an application and send it to J. A. Shepard, temporary chairman, care of the Shepard Electric Crane & Hoist Co., 30 Church St., New York City.

Chlorine Price Cut in Half

A contract for liquid chlorine for water treatment has been awarded by the City of Chicago on a bid of 8c. per pound, while market prices until recently have been 14 to 16c. The contract, given to the Hooker Electro-Chemical Co., Cleveland, Ohio, is for 400,000 lb. for the 1919 supply, delivery to be made as required by the city.

Business Notes

Charles H. McCullough, Jr., was elected president of the Lackawanna Steel Co. at a recent meeting of the board of directors. Mr. McCullough has been vice-president and general manager of the company, and succeeds Edward A. S. Clarke, who resigned a week ago.

S. M. Williams, president of the Highway Industries Association, and for the past four years sales manager of the Garford Motor Truck Co., has been relieved of his duties as sales manager to take charge of the new department of highway development which has been established by the company.

Walter N. Polakov, consulting engineer, 31 Nassau St., New York, announces the founding of Walter N. Polakov & Co., Inc., consultants in power-production methods, industrial investigations, labor problems, scientific record systems and production accounting.

The Brown Hoisting Machinery Co., Cleveland, Ohio, announces the following changes in its organization: Harvey H. Brown, chairman of the board of directors; Alexander C. Brown, president; Melvin Pattison, vice-president, general manager and director.

Trade Publications

The American Zinc Institute has issued its 1918 bulletin. It is a 5-p. folder outlining the aims of the institute and the reasons for its formation. Other information of interest to zinc users is given.

The American Manganese Steel Co., Chicago, Ill., has issued a new catalog on sand and gravel pumps, which they announce is for distribution among those interested in pump installations. It is a 6 x 9-in. pamphlet of 22 pages, punched for filing in a loose-leaf binder.

"Home Building with Metal Lath and Stucco for Permanence and Safety" is the title of a 7 x 9½-in., 20-p. catalogue issued by the Associated Metal Lath Manufacturers, Woodward Building, Washington, D. C. It illustrates and describes residences and buildings in which their product is used.

The Denver Rock Drill Manufacturing Co., Denver, Colo., has issued a leaflet describing its model 110 Waugh drill steel punching machine which, the company states, is one of its latest products.

Waterworks

PROPOSED WORK

Mich., Ferndale (Royal Oak P. O.)—G. Jerome, engr., 1331 Majestic Bldg., Detroit, receives bids about Feb. 1, furnishing and laying water mains for complete water system for village. About $99,000. Noted Dec. 5.

Wis., Oshkosh—City will sell $50,000 bonds Jan. 17, to improve water-works. A. March, comptroller. Noted Dec. 26.

Minn., Fairmont—City receives bids in February or March building 1,000,000 gal. water purification plant. C. H. Currie, Webster City, Ia., engr.

Minn., Minneapolis—Golden Valley Golf Club plans to extend water system at Golden Valley, 5 mi. west of here. About $20,000. E. Von Ende, 651 Plymouth Bldg., secy.

Kan., Eldorado—Black & Veatch, engrs., Interstate Bldg., Kansas City, Mo., making survey of water system and investigating feasibility of building ground water supply and dam for collecting and holding water up river.

N. D., Belfield—City receives bids in spring building water-works system, including rein.-con. pump house, c.i. pipe, mains, rein.-con. reservoir, etc. Former bids rejected. L. P. Wolff, 1000 Guardian Life Bldg., St. Paul, Minn., engr. Noted Sept. 12.

Mont., Ft. Benton—City election Jan. 17, to vote on $35,000 bonds to improve water-works system.

Wash., Spokane—City plans to install steel and iron headgates, with operating devices at Upriver pumping plant to replace old timber headgates on masonry dam, cost $30,000; also replacing 6 mi. wooden water pipes with 6 in. steel mains. Will purchase equipment and install same by day labor. A. Lindsay, supt.

Que., Lachine—See "Industrial Works."

Sask., Assiniboia—City plans to complete water-works system. About $20,000. Address J. Nolan.

BIDS DESIRED

Mich., Detroit—Until Jan. 14, by H. S. Starkey, secy. water comn., 232 Jefferson Ave., furnishing 1000 tons 6 in. c.i. pipe and 1000 tons 8 in. c. i. pipe. G. H. Fenkell, 232 Jefferson Ave., engr.

Ont., Pembroke—Until Jan. 10, by town clk., furnishing 1600 lin.ft. 20 in. c. i. pipe, 15 flexible joints, two in. gate valves and 1 screen for water-works intake. W. J. Moore, town engr.

PRICES AND CONTRACTS AWARDED

(★Indicates award of contract)

Mich., Wyandotte—City received bids Dec. 30, (1) furnishing and laying 1450 ft. submerged intake pipe and elbows equipped with flanges and joints, removal of existing elbow, relocating existing crib, final testing, dredging and backfilling and all labor and material, involving 1450 ft. 24 in. c. i. pipe. Alternate bids on (a) Fenkell joints, (b) Ward joints, (c) Metropolitan joints, (d) Walker flexible joints; (e) according to bidder; (2) building filter plant with 6,000,000 gal. daily capacity, composed of six filter units, 21½ x 24 ft. of 1,000,000 gal. capacity each, 40 x 65 ft. and 37 x 73 ft. brick and steel filter and head houses, 2 coagulation basins, 64 x 94 ft. each, filtered water reservoir having capacity of 850,000 gal., usual equipment of hydraulic valves and controllers and 32 x 50 ft. brick addition to pumping station, (a) using concrete piles with alternate on reservoir; (b) using wood piles with alternate on reservoir, from Amer. Constr. Co., 1552 Rockefeller Bldg., Cleveland, O., (1a) $55,340; (1b) $52,155; (1c) $52,155; (1d) $53,155; J. H. Baer, Penobscot Bldg., Detroit, (1d) $51,750; (1e) $48,632, Class "B" pipe with Walker flexible joints at 72 ft. intervals; Lennane & McIlvenna, 809 Union Trust Bldg., Detroit, (1d) $45,000; Great Lakes Dredge & Dock Co., 1630 Williamson Bldg., Cleveland, O., (1a) $49,300; (1c) $60,900; (1e) $51,475, ordinary B & S pipe Class "B" with Thatcher joints; A. O.

Volume 82 — NEW YORK, THURSDAY, JANUARY 16, 1919 — Number 3

States Should Attack Reconstruction Problems

RECONSTRUCTION problems have received so little attention at Washington, and Congress seems so unlikely to do anything adequate before adjournment, that the several states must act if danger of great injustice to soldiers and war workers and of serious industrial disturbances is to be averted. Some states have it within their power to provide work through highway and other construction. Many can aid by removing various state restrictions which prevent cities from making needed improvements. All states can and should establish or continue state agencies to deal with reconstruction problems. Such bodies should lose no time in making broad surveys of the field, with a view to determining needs and ways of meeting them and obtaining necessary legislation at the earliest possible moment.

Congress Should Unlock Water Powers

PASSAGE of the Congressional water-power bills now in conference is earnestly to be hoped for before the close of the present session. Every engineer who is familiar with the water-power situation will agree that prompt action is needed. Water-power needs to be unlocked, to conserve fuel and to furnish profitable employment to the men released from military service and munition making. The present Congress has given more attention and study to this vital matter than any previous Congress. Its work should not be lost, especially at this critical time. Even if the bill as finally reported should be more or less of a compromise and defective in many particulars, yet if, without undue sacrifice of vital interests on either side, it opened the way for even a limited development of unused water powers, it would be well worth while as a contribution to the solution of reconstruction problems and to the conservation *and utilization* of our natural resources.

Too Late Is No Better than Never

MORE and more it becomes apparent that public works are the only reservoir which will tide us over the almost inevitable unemployment crisis approaching in the construction field. That reservoir must be made ready immediately, and not delayed, as seems the prospect in most of the proposed projects. In Cleveland, for instance, with great flaunting of headlines it is announced that the mayor is now planning to furnish employment during the reconstruction period, by going right ahead with the $3,500,000 East Side filtration plant. So far the announcement seems hopeful, but one reads farther and sees that it is expected that ground will be broken "the latter part of this year." So far as helping present needs is concerned, such a plan is about as useful as would be a scheme for huge landing places for the transatlantic airplanes which the optimists tell us will be flocking across the ocean within the decade.

Taking State Highway Routes Out of Politics

VARIOUS plans have been devised to keep the designation of the routes to be followed by state trunk highways out of politics, but generally without success. Log-rolling to bring the improvements to locations where they will do the most good to the particular crowd of politicians in power has always been a disorganizing factor, and one which has put peculiar "kinks" in many systems. To eliminate this troublesome interference, the highway officials of Minnesota propose to map out a system and submit the map to vote of the people, as a part of a constitutional amendment (noted in *Engineering News-Record* of Dec. 26, p. 1199) necessary to enable the state to enter upon highway construction. In laying out the roads, tentatively, they have been proportioned to the various parts of the state according to assessed valuation and population, and, if approved, each section will know just what roads it is entitled to. Such a plan has the advantage of fixedness in any event, and if any "fixing" is done in the original layout, the people will be in a position to see the results before voting. The object of the plan—freeing highway routes from log-rolling—is most commendable, but it is a pity if there is no way of doing it short of making the proposed highway routes a part of the state constitution. Such documents should be confined to fundamental principles and not lumbered up with administrative details.

A Daring Adventure In Municipal Ownership

SEATTLE is making a daring adventure in municipal ownership. As noted on p. 163, the city authorities have taken action to buy the local street-railway system. British and some continental European cities set the example long ago. San Francisco has municipalized an important street railway line or two, and Seattle already has a short line of its own. New York, Boston and Philadelphia have put millions into subway construction for private operation, and Cincinnati launched a similar project before we entered the war. Seattle, if it goes forward as rapidly as is expected, will be the

pioneer American city of considerable size to own and operate its entire street-railway system. Whether the present difficulties besetting many of our privately owned street-railway systems will lead to an early extension of municipal ownership is an interesting question. At this critical juncture in local transportation, perhaps it is well that some American city should make a trial of complete municipal street-railway service. Seattle has volunteered.

Philadelphia Again Pays Heavy Penalty

AMONG the good features proposed for insertion in a new charter for Philadelphia under consideration by a voluntary charter committee is one that would authorize long-term contracts for some city services now restricted to yearly contracts. The need for such a reform as to garbage disposal has been pointed out again and again by *Engineering News-Record* and its predecessors. It was recently illustrated anew by a contract award for garbage disposal in 1919 at an advance of $123,636 over the 1918 contract. Earlier last year a bid at a reduced price was received, but for reasons presumably connected with the one-year contract system it became necessary to readvertise the contract twice. As was to be expected, with a new contract beginning Jan. 1, and requiring an extensive plant, there was no competition. The legislature has been asked in vain to authorize long-term garbage contracts for Philadelphia. It gives heed to the interests of contractors and politicians instead of to the pocket books of the citizens of Philadelphia. Possibly this evil, in common with others with which Philadelphia is burdened, may be remedied by a new charter. Unquestionably, they might be if the people would prove by an aroused united effort that Philadelphia is no longer "corrupt and contented." What are the engineers of Philadelphia doing about it?

Look Well to Choice of Camp Cook and Save Money

FOOD waste is characteristic of construction camps, as it is shown by Captain Tharaldsen on p. 146 to be characteristic of lumber camps. Perhaps waste is not so large in construction camps, but the causes are the same. The remedies outlined in the article apply to construction as well as to lumber camps. Camp messes in general fail more because of poor cooks than because of limited variety and poor quality of supplies. This fact makes of prime importance the task of selecting a camp cook. Captain Tharaldsen's remarks on this point deserve emphasis. The position of camp cook is not a menial one which any "pot slinger" can fill even in a small camp. When several hundred men must be kept fed and satisfied, it is a position which only a man having knowledge of foods and menus, and catering generally, can fill and keep the men contented and the costs moderate. No construction employee should be hired with greater care to determine his skill and responsibility than the camp cook. Few workmen can, because of personal inefficiency, directly and indirectly cost the job so much money as its cook. With the higher standards of catering set by war construction as examples, there will be more need than ever for the contractor to look well to the quality of his camp mess.

Motor Trucks Needed To Supplement Not Compete With Railways

THE radical changes in manufacturing industries resulting from the suspension of hostilities and the cancellation of munition contracts are paralleled by the changes in the transportation field. The competition between the railway and the motor truck is entering on a new phase. The motor truck has been an invaluable aid in the munitions industry, especially during railway congestion, because it could give prompt deliveries. Cost of service has been a minor consideration.

That condition has passed. The manufacturers and merchants are looking after their freight bills as sharply as they do to their purchases of goods; and to hold its place the motor truck must show as low a cost, all things considered, as the railway.

During the traffic congestion resulting from the war the railway managers have rather welcomed the diversion of business to motor-truck lines. With the relief of congestion the railways, naturally and properly, are seeking to regain their business, for profits in railway transportation depend directly on the volume of traffic, until the point of congestion and delay is reached.

Certain railway managers are making a careful study of truck transport costs in order to determine the field in which they can expect to regain business. Realizing that one chief advantage of the motor-truck service is prompt delivery, railway managers are making plans for a more rapid and systematic handling of small merchandise shipments over short-distance routes.

As several contributors have pointed out in the columns of this journal recently, the railway and the motor truck ought to supplement each other. Every engineer will heartily approve the recent declaration of Director General McAdoo, "Upon the efficiency of the transportation machine in America depends in great measure the future prosperity of the nation." This efficiency can only be secured by furthering the use of whatever type of transportation that can render the service desired at the lowest cost.

There is an enormous field for the motor truck in reducing the present heavy cost of terminal hauling—using that term in its broadest sense to include short-haul business between cities. It ought to be more generally understood that this is where the need and the opportunity for the motor truck lie and not in competing with the railways for traffic over long-distance routes.

When freight has been loaded into a railway car, made up in a train, and started on its journey, the railway can haul it at a cost per ton-mile which is often not 2% of the cost of hauling by motor truck. The average cost per ton-mile for all freight moved over the Pennsylvania R.R. in the year which ended June 30, 1916, was only 0.43c. This includes, of course, all the expense of handing in railway terminals as well as hauling over the road. Even on railways of very light traffic, the cost of hauling freight over the road seldom exceeds 2c. or 3c. per ton-mile. In contrast with this, the cost of hauling freight by motor truck, even over good roads, is seldom less than 15c. per ton-mile, and often exceeds 25c. This does not include, either, the interest, maintenance and depreciation charge on the road over which the truck runs.

The advantage of the motor truck over the railway lies in its ability to transport goods from the original to the final destination without rehandling. This eliminates the terminal expenses of the shipper and receiver as well as those borne by the railroad itself. These terminal costs on most merchandise shipments are several times the cost of hauling by rail, even when the distance is considerable. It is not at all uncommon to have the cartage charge on a freight shipment at destination equal the railway freight charge on a haul of several hundred miles. The larger the city, the larger, as a rule, are the costs of the terminal handling, both to the railway and to the shipper. The repeated rehandling of goods necessarily is, of course, a large element in these terminal costs, and on certain classes of goods the loss and breakage likely to occur in such rehandling counts very heavily in favor of the motor truck.

This whole matter is not one that interests merely the builders and operators of motor trucks and the railways. Its vital relation to the public welfare is obvious from the quotation from Director General McAdoo, already given. It is not possible to reduce much farther the cost of transportation by railway over long distances, but there are great opportunities for reducing the costs of movement at both ends. The problem here, furthermore, is as much a problem of organization as it is of the proper use of both railway and the motor truck to accomplish the work to which each is best adapted.

Is Interstate Communication Local?

ONLY a week or two ago the War Department reported against giving Federal aid to the construction of a highway tunnel under the Hudson River at New York, on the ground that such an improvement would serve local traffic and benefit local interests. Within the past few days, however, the Government has intervened in a boatmen's strike which stopped communication across the river, and thereby it has acknowledged in unmistakable manner the national importance of this communication.

If the port of New York—physically a unit, but cut in two by the New Jersey-New York state line as regards construction, planning and administration—concerns the nation sufficiently that the Federal Government may take a hand in its intercommunication problems, what shall be said of other places where there is interstate communication? Hitherto the Government has hesitated to approach problems of communication and transportation that are localized at state lines, though these are preëminently problems of interstate commerce. But what has been learned in the past two years about the urgency of transportation questions suggests that the time has come for a change of attitude.

Consider, as an example, the case of the Hudson River, which for 150 miles splits the country in two, without a single road connection and but one railway crossing. In this stretch the Federal Government has spent millions of dollars for facilitating traffic along the river, but not one dollar to help carry traffic *across*. No reason exists for this discrimination except policy founded on an ancient tradition: That rivers are proper subjects for Government appropriations, while bridges and tunnels are not. Shall we continue to let tradition control the allotment of vast sums of public money to works of construction?

Every important river forming a state boundary shows the same conditions existing. As in the case of the Hudson, each instance gives proof that interstate communication is important, and that it has become sunk in general neglect. Local interest, as experience has shown time and again, furnishes no incentive for dealing with the subject broadly, to take care of the whole country's interests.

The national concern in the question, then, is obvious. Interstate communciation is not a local issue. To secure the best adjustment of national, state and local interests in a specific case will not always be an easy problem, but the adjustment will be quite impossible so long as responsible Government departments continue to be guided by tradition rather than by present-day need.

Are Engineering Educators Seizing Their Greatest Opportunity?

ONE of the illuminating statements in the symposium from the deans of various engineering schools upon the effects of their experience with the Students' Army Training Corps (see *Engineering News-Record* of Jan. 2, p. 41, and p. 138 of this issue) is that by Dean Snow, who quotes the popular phrase, "We do not know where we are going, but we are on our way." A review of the replies in answer to the question on future needs and opportunities in engineering education and how they can be met will disclose a discouraging lack of definite ideas, in spite of the fact that the greatest success will come to those educators who best foretell the demands of the future. Do American educators need a reawakening to develop teacher-leaders in applied science? Is it too much to expect a combination of great power of achievement, such as America has shown in the war, with leadership in science? Can we not insist upon a degree of excellence in our schools and colleges such as we have just demanded from industry during the war? Is H. G. Wells right in calling English and American education a "loafer education" as compared with German depth and thoroughness? Have we in the past failed to develop power of sustained mental effort in the graduates of our engineering colleges?

These questions are now receiving the serious consideration of engineering educators, many of whom have been profoundly influenced by their recent experience. For while many colleges are returning to pre-war courses, yet individuals and committees are discussing proposed changes, and studying Dr. Mann's report with its "suggested solutions." Few have made or announced definite changes—some give an impression of being self-satisfied. The majority favor fewer highly specialized courses and a more thorough training in the fundamental core sciences. There is a general agreement that one result of the experience will be a peace issues course, similar in character to the war issues course given in all the S. A. T. C. colleges, to demonstrate the meaning of engineering work in the life of the world. One of the big lessons of the war is the possibility of arousing exceptional effort through the power of a real incentive.

The war experience suggests a solution of the problem of how to provide bread-and-butter training and at the same time meet the need for broadly educated men of limitless possibilities. This solution is a combination course coördinating general with highly specialized courses, using both the spur of discipline and the drawing power of incentive. The latter may be developed by showing the worth of academic effort, by tying it up to actual engineering work. In this combination, which in favorable localities may mean coöperative courses, such as developed by Dean Schneider at Cincinnati, the weakness of both extremes will be overcome—the superficiality and "bluff-it-through" attitude of graduates of general courses on the one hand and the narrow, materialistic results of overspecialization on the other.

The serious question of time limit in a four-year course should be met by using more of the synopsis method and leading the student to read and investigate for himself. This would develop originality and initiative, the necessity for which has been shown, by our war experience, to be so essential. Fewer lectures, refusal to permit teacher-specialists to dominate other departments, new tests for measuring acquired knowledge which will combine the objective tests proposed by Dr. Mann with the usual examination methods, would all tend in the right direction.

Perhaps the greatest need is for teachers with broad vision and practical experience in engineering life. Administrators of technical schools must realize that no price is too great to pay for educators capable of lifting the profession, through their influence on its young men, to new heights of accomplishment.

Government Directors for Railway Corporations

IN THE illuminating discussion of the question of what to do with the railways, by L. C. Fritch, in *Engineering News-Record* of Jan. 2, p. 18, one suggestion in particular is so important and valuable that it ought to be incorporated in any plan involving the return of the railways to company control.

Mr. Fritch urges that in addition to supervision by the Interstate Commerce Commission there should be on the board of directors of each railway company men appointed by the Government to represent the interests of the public. He says: "The policy of selecting able representative business men to act for the Government in such capacity would result in business management of the railways in the interests of the public, and would have a wholesome effect in railway administration."

This, we believe, is one of the most constructive and fruitful suggestions which has been made in the public discussion of the subject. Everyone agrees that there must be established a firm control over railway operations in the public interest, if they are to be returned to the companies. But all regulation by a commission, however constituted, is regulation from outside. What is needed in the public interest, and in many cases in the interest of railway security holders as well, is regulation from inside.

At any previous time it would probably have been impossible to have carried out such a reform successfully, because of the antagonistic attitude which would have been assumed toward such Government regulation. Railway managers and financiers, however, are viewing things through very different eyes from those they used half a dozen years ago, and Government-appointed directors of the right type would not have the uphill fight that would have been their portion a few years ago.

We say, "Government directors of the right type." Of course, if the authority to name directors to represent the public were made use of by the Government to take care of "lame duck" Congressmen and other needy politicians, or to put bureaucratic hacks in a position to exercise authority, the Government directors would be figureheads or worse.

Real and Unreal Progress in Steel Working Stresses

IF THE majority of the structural engineering profession of the country were in accord with the ultra-conservative limitation of column working stresses to 12,000 lb. base, as recommended by the Column Committee of the American Society of Civil Engineers a year ago and now reflected in a few new specifications, there would be reason to fear that engineering judgment is at fault. Structures proportioned for much higher stresses have given satisfactory service for many years, without the least symptom of trouble from excessive column stress. In view of this service efficiency, there is no solid ground to support the claim that steel columns loaded above 12,000 lb. are unsafe; on the contrary, the facts of experience must be taken to prove that a 12,000-lb. limitation will mean a waste of material.

There has been enough criticism of the committee's recommendation to make it probable that practice will be slow to accept it. Individuality of thought is a necessary factor in bridge engineering; committees, however, are often dominated by conservatism or even timidity. It is natural, then, that engineers should protest—as does Dr. Waddell in this issue—against any straitjacketing of structural judgment by the result of such tendencies.

Further tests on columns are surely desirable. But Dr. Waddell suggests a new kind of testing, using a truss or a bridge as a testing machine. The method has attractive aspects, but do we need it? Will it aid progress toward safety and full utilization of material?

The tests conducted for the Civil Engineers' committee, though laid out on a narrow plan and leaving many practical conditions unrepresented, yet produced data that establish a satisfactory basis for judgment on the strength of steel columns. Additional tests, then, should be precise experiments on specific questions of detail. To complicate such tests by introducing the elusive and erratic influence of truss distortions is not likely to meet this requirement.

However, if further testing of heavy members is to be initiated, tension members offer the field of greatest promise. It is true we have ample data on eye-bars. On the other hand, less is known about the strength of the large riveted chords and diagonals of modern bridges than about any type of compression member. It may well be said, therefore, that tensile working stresses are involved in greater uncertainty than column stresses.

Despite this fact, a tendency is distinctly observable toward increase in tensile unit stresses even while—since the report of the Column Committee—the compressive units are being pared down. It is remarkable that this should be the case, in the absence of test knowledge. Manifestly, those who propose to increase stresses aim in the direction of true progress, by way of safety and economy. But we think it may be fairly objected that they secure these objects in divided form—safety in the compression members, economy in the tension members. Is it not necessary, at this stage, to inquire whether test data and sound judgment warrant a raising of tensile stresses to eighteen or twenty thousand pounds and a lowering of column stresses to twelve?

While refinement of analysis and design has been helping us on toward maximum utilization of material, we have adhered to the large margins of ignorance that were established in the early days of the structural art. An increase of working stresses, then, is needed, and if all signs do not fail such increase is sure to come about —at least for those structures which do not involve the perplexing uncertainties of change of railway loading. These stress increases, however, will be based on dependable knowledge of strength, test knowledge, or they cannot be permanent steps of progress. Change such as represented by an indiscriminate increase in the tensile units, while we know nothing whatever concerning the strength of large riveted tension members, is not entitled to rank as true progress.

Electric Drive for Warships

IN THE great superdreadnought "New Mexico," as our readers are well aware, the United States is possessed of the first electrically driven battleship in the world. True enough, we have already had a "trial horse" in the collier "Jupiter," which proved a rather conspicuous success, but the step from a collier to a fighting ship of the highest class is a considerable one, and it is gratifying to know that it has been most successfully taken.

There is nothing mysterious about the general principle involved—that of a high-speed and light-weight generating set furnishing current to variable-speed driving motors. To all intents and purposes, the electrical part of the equipment is a very efficient variable-speed reducing gear. The basic idea behind the electrically driven ship was the intent to take advantage of the great simplicity, compactness, convenience and weight efficiency of the steam turbine, so as to adapt it to marine purposes. No one would have had the least desire to use electrical drive in connection with reciprocating engines.

The steam turbine, of course, in its present stage of development, possesses the qualities just mentioned in an extraordinary degree, and the one thing which stands against it is that these qualities are virtually dependent on the extremely high rotative speed necessary for efficient design, a speed at least ten times greater than can be advantageously used on the propellers of a large ship. To utilize the steam turbine in marine practice implied either an enormous increase in the propeller speed or a great reduction between the turbine and the screw. The former alternative implies, owing to increased friction and slip, a very great loss in the propeller efficiency, so great that it would outweigh, several times over, any conceivable gain by the use of the steam turbine instead of the reciprocating engine. But at its best the steam turbine has such remarkable efficiency from the thermal standpoint that one can readily afford the losses in almost any sort of well-designed reducing gear. As an example of what a turbine can do, it is only necessary to quote the guaranteed performance of a turbine recently installed for land service, which at 14,000-kw. load brought the steam consumption down to 10.45 lb. per kilowatt-hour, equivalent to 0.78 lb. per brake horsepower-hour. Obviously, at this low steam consumption one could well afford considerable loss in a reduction gear while still retaining a fuel consumption of about one pound of coal per horsepower-hour. On the other hand, the losses in trying to use a propeller at the turbine speed would more than nullify the advantages of a turbine.

As between the mechanical gear and the electrical gear as a means of speed reduction, the advantage of cost and weight lies with the former, but that of speed control, subdivision of power in the propellers, and general flexibility, enormously with the latter. In the mechanical sense, too, the electric drive is almost frictionless, the losses being thermal instead of mechanical, and so not expressible in terms of wear. So, whatever success may have been attained with gearing in relatively simple cases for naval use, the electrical gear was a logical recourse. One need not go here into details of the equipment of the "New Mexico," which will undoubtedly be very fully described, now that the war is at its close, in the technical journals specializing in such matters. In brief, she is equipped with two 11,000-kw. turbo-generators which furnish the power to four 7000-hp. driving motors. As the induction motor is essentially a constant-speed machine, the intermediate and lower speeds are obtained by varying the turbine speed, which can be done within moderate limits without too serious effect upon its efficiency. For low speeds one generating set can handle any or all of the motors that may be necessary, and either set can be put upon any motor connection that is necessary.

This arrangement gives a beautifully efficient and flexible drive, and its advantages for naval use are of momentous importance, perhaps not yet fully realized. In fact, it is probably not too much to say that the electric equipment of the "New Mexico" opens a new era in naval architecture. The dimensions of the turbo-generators and of motors are such that they can be kept low in the ship, exceptionally well protected beneath the water line and armor. The motors, too, can be located so as to maintain the best structural relation to the propellers which they drive.

The United States stands committed already to six battleships and five battle-cruisers equipped with electrical drive, and the success of the "New Mexico" is prophecy of the great future that lies before the system. Nor is it likely to be confined to ships of the battle line, for its advantages would be especially valuable in the large, fast cruisers which form the everyday working force of a well ordered navy, ships uniting great radius of action, very economical cruising speed for their long swings about the Seven Seas, and prodigious power when it is necessary to drive them.

Huge Steel Buildings at Ordnance Base Depot in France

Project Includes Both Shops and Warehouses—All Material Supplied from United States—Ten-Mile Transmission Line Built to Supply Electric Power for Machine-Tool Operation

By Robert K. Tomlin, Jr.
War Correspondent of "Engineering News-Record"

This article was written last summer and delayed in transmission. It is published at this time just as written by Mr. Tomlin, because of the great interest in the work of our engineers in France.—Editor.

Into the construction and equipment of the main Ordnance Base Depot for the American Expeditionary Forces is entering about 60,000 tons of material, practically all of it shipped from the United States. Covering a site of many acres, the 10 big steel structures, now almost completed, represent one of the largest building projects undertaken by United States forces in France. Certainly, it is the largest project involving the exclusive use of structural steel; yet, in spite of the diversity in size and character of the several buildings, standardization has been carried to such a point in the designs prepared for the Ordnance Department by the firm of Stone & Webster that only 148 different kinds of pieces are required for the entire work, this number including not merely main steel members, such as columns, rafters and purlins, but also such small accessories as anchor-bolts, tie-rods, clips and angles.

The buildings already erected (Aug. 15) comprise the following: Two gun-shops, each 245 x 600 ft. in plan; one reamer shop, 182 x 240 ft.; two warehouses, each 240 x 500 ft.; one carriage machine shop, 227 x 500 ft.; one carriage assembly shop, 240 x 500 ft.; one woodworking shop, 200 x 320 ft.; one forge and foundry shop, 160 x 245 ft.; one substation, 40 x 60 ft. This program alone represents steel-frame buildings covering a ground area of 917,000 sq.ft. As future possibilities there are, in addition, two tractor shops, each 245 x 600 ft.; two warehouses, each 240 x 500 ft., duplicating those already built; and a small-arms shop 240 x 500 feet.

All Material Shipped from America—After an investigation of the material markets of France more than a year ago, it was decided to send over from the United States everything needed for building and fitting out the ordnance shops and warehouses. This meant a tremendous amount of advance planning, for provision had to be made not merely for the structural-steel frames, roofing and glazing, but also for a big schedule of machine tools, cranes, electric-lighting fixtures, power equipment and construction plant. The job had to be figured down to the smallest detail, purchases made in America and shipping schedules laid out.

The unusual character of the work, in which the questions of a 3000-mile transatlantic trip for everything entering into the construction, and the probable use of labor entirely unfamiliar with steel erection, were the controlling features, made the preliminaries a subject of prime importance. To have started work in France and then to have discovered that something had been forgotten would have meant not a delay of a few weeks waiting for its arrival, but a setback of months, for material could not be delivered quickly from the United States to France under conditions of shipping existing early in 1918. Foresight in ordering materials has been a big factor in aiding progress.

FIG. 2. DETAIL OF COLUMN FOOTINGS, SHOWING CORRUGATED IRON FORMS FOR CONCRETE

History of the Project—The history of the Ordnance Base Depot in France dates back more than a year, when the contract for the design, purchase of materials, and supervision of construction was awarded to the Stone & Webster organization. The project as originally laid out was described in *Engineering News-Record* of Jan. 3, 1918, p. 13. Many changes, both in the actual layout and the handling of the work, have taken place since those days. It is worth while to present a brief historical outline, for without it no true conception of the project and the working conditions is possible.

Unlike most of the Army engineering work in France, the Ordnance Base Depot has involved the participation of a civilian organization, not only in the design but also in the handling of materials and the supervision of construction. This resulted in the creation of certain special conditions which had their influence on the conduct of operations in the field. To begin with, a civilian organization in the American Army zone of France is not in a position to order things done by military units. There must always be some intermediary. This applies not merely to the actual handling of labor, but to another matter equally as important—transportation of materials. The site of the job is quite a distance from the nearest base port, and, in fact, from the nearest railway station. When railway cars or motor trucks are needed, arrangements for them cannot be made directly; everything must go through military channels.

The status of the civilian representatives was, therefore, somewhat anomalous. As events have turned out, their duties have been largely supervisory. Instead of officially directing the job, and being responsible for its progress, the civilian engineers and superintendents have acted as consultants, rather, giving advice as to the conduct of the work and placing their construction experience at the disposal of such officers as cared to avail themselves of it.

Labor Scarce—One of the earliest difficulties encountered was the matter of labor. The intention was to have the Ordnance Base Depot built by the enlisted personnel of the Ordnance Department, with the Stone & Webster representatives acting as superintendents. The vanguard of the Stone & Webster forces had arrived in France in September, and about the middle of October the Ordnance Department officers who were to have immediate supervision of the project arrived. After some time was spent in examining possible sites for the plant, a definite location was fixed late in October, 1917, and steps were taken to obtain the land from the French. One of the first jobs to be done was the construction of a railroad siding connecting the site with the nearest French railroad line, for material was beginning to arrive in France and means were needed to deliver it to its destination. As all sidings, railroads, camps and other accessories for this project had been assigned to the Army engineer troops for construction, a detachment of engineers was placed on this work and the siding was put in the latter part of January, 1918.

While this was the first step in actual progress, other difficulties were to follow. There were no unloading facilities at the site in those early days and labor was scarce, as a detachment of ordnance troops scheduled to arrive had not reached the job in the numbers expected. Meanwhile, the engineer troops which had put in the railway track began to construct barracks for the working force, and finally began the actual job of putting up the steel buildings for the base depot. In the meantime a detachment of 600 Chinese had appeared on the scene and they were set to work unloading cars and distributing material.

As time went on, however, material still continued to arrive, the labor force began to build up, and the civilian representatives continued in an advisory capacity, assisting in the layout of the work, the routing of materials and the supervision of the steel erection. Ordnance and engineer units in varying numbers came and went, and by the middle of April about 1200 men were on the job. Since then, the force has carried between 1200 and 3000, and on July 1 it numbered about 2500.

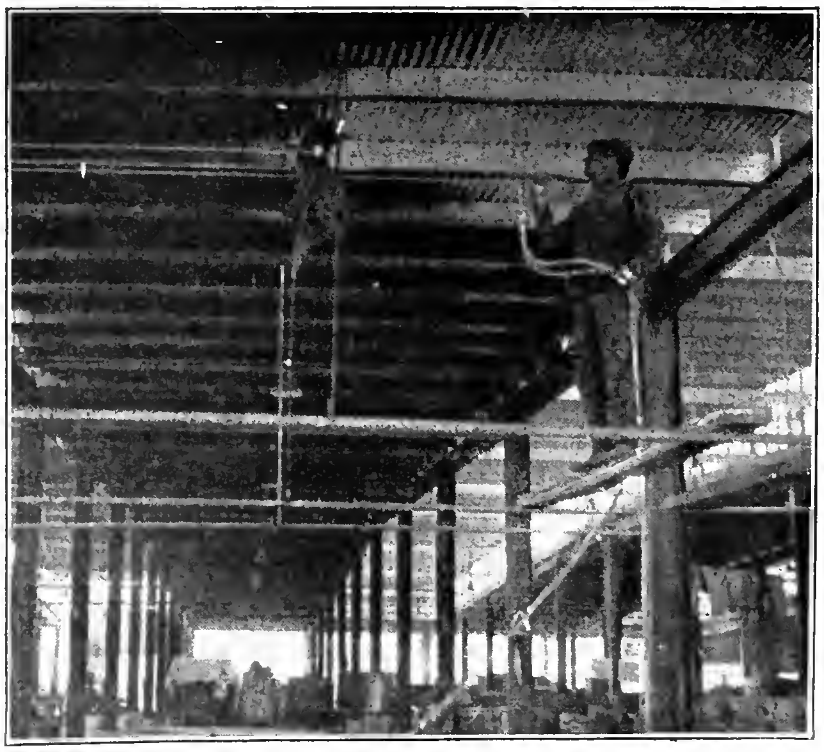

FIG. 3. INTERIORS OF STEEL STRUCTURES ARE PAINTED WITH COMPESSED AIR SPRAYS

The labor force, however, was never constant. In the case of detachments, these would come and go, or, even if they remained, details would often be removed from construction operations and assigned to other duties. The conditions with respect to these troops

are best expressed by one of the officers who, in discussing the difficulties due to the lack of a permanent working force, said that many of the detachments he received "merely filtered through the job." It became necessary, therefore, to train successive batches of men as they arrived, and to lose the benefit of this training when they were removed. The engineer troops, however, remained, and their number was greatly increased by the addition of other units.

FIG. 4. CONCRETE FOR MACHINE TOOL FOUNDATIONS CARRIED IN METAL-BODIED WHEELBARROWS

Between the commanding officer of the engineers and the members of the Stone & Webster organization still on the job there has developed a spirit of cordial coöperation. In fact, during my visit to his headquarters, this engineer officer said to me: "Too much cannot be said for the help which has been rendered by the civilian superintendents and engineers. We are all glad that we have had them here on the job."

Additional engineer battalions arrived at the Ordnance Base Depot site about Mar. 1. In reply to my question as to what he had available for commencing work, Major F—, commanding, replied, "Nothing but snow." He started his men on excavations for the column footings of the big steel buildings and assigned a labor crew of about 500 Chinese to unloading material which was beginning to arrive in large quantities on the newly built sidings connecting with the double-track French railroad.

In the early days of this work everything had to be unloaded by hand, as no locomotive cranes had arrived. It was no easy job to remove some of the steel members from the short French railroad cars, on account of the limited clearance at the ends. With the material out of the cars the problem was by no means solved, because at this time of the year, with the frost leaving the ground, the site was a veritable mud sea—so soft, in fact, that the two-wheel pick-up carts used later for transporting steel columns, rafters and purlins sank in so deep that they could not be moved. At this time all of the steel-work was transported from railway truck to building site in slings carried by Chinese.

There are in the new ordnance depot two general types of building, the warehouse and the shop. The warehouse structures have 10-in. I-section columns spaced 20 ft. on centers, all of the columns being of one length and therefore interchangeable. The roof slope is obtained by varying the elevations of the concrete footings on which the columns rest. The steel frames of the warehouse buildings are sheathed with plain, corrugated, galvanized-iron sheets. A single warehouse structure 240 ft. wide and 500 ft. long involves the erection of 410 tons of steel. Including other accessories, such as corrugated siding, roofing, doors and glass for windows, the total weight of the material entering into a warehouse of the dimensions given above is about 700 tons.

FIG. 5. PACKING CASES SUPPLIED ALL THE WOOD FOR FORMS OF MACHINE-TOOL FOUNDATIONS

While the shop buildings are of the same general type as the warehouses, they differ in certain important details. In the first place, structures such as the big gun-shops will be equipped with traveling cranes in every bay. The column spacing for the shop buildings is 35 ft., as compared with 20 ft. for the warehouses. The columns themselves are heavier, built-up members, in order to carry the crane loads. In the case of the shops, the roof slopes are not obtained by varying the elevations of the column footings, but rather by setting at the proper elevations, by means of a flexible splice, light extensions of the main columns. In other words, the heavy columns are bored with holes for some distance at their tops, and the lighter extension members supporting the roof are bolted to them at the the elevation desired.

FIG. 6. CRANE WHICH HANDLES EXCAVATION FOR GUN-SHRINKING PIT

In the matter of the concrete footings for the columns there is also a difference between the warehouse and the shop structure. In both cases the footings are cylindrical. A plain footing serves for the warehouse, inasmuch as the columns carry only the dead

loads of the roof, but a spread footing is used under the shop columns which support the craneways.

In one other detail also the two types of buildings differ. Warmth in the completed warehouse structures is not a matter of any great importance, and the sheathing, therefore, is of plain, corrugated sheets, galvanized. In the shop structures, however, the force of men will be at work winter and summer, and to conserve heat the sheathing adopted for the sides is asbestos-protected metal.

As indicated in the first paragraph of this article, every effort has been made in the design to standardize the lengths and cross-sections of members and to reduce to the minimum the number of all the different kinds of pieces. All connections are bolted and only two sizes of bolts, $\frac{5}{8}$-in. and $\frac{7}{8}$-in., are employed. The fact that all of the huge structures indicated by solid black lines in Fig. 1 have been erected by labor a large percentage of which had absolutely no previous experience on steel-work is a tribute not only to the engineers who supervised the erection, but also to the men who designed the structures which could be thus handled in the field.

One detail of the spread footings for the shop building columns should be noted. Practically no wood was available for concrete forms, and it will be seen from Fig. 2 that corrugated sheets intended for the siding of the buildings have been bent and employed for concrete forms.

In the early days of the steel erection, which was started Mar. 28, no plant was available, and gin-poles were rigged and used for hoisting the roof members into place. Later, however, auto-cranes of the type shown in Fig. 10 and hoisting engines (see Fig. 9) arrived and greatly expedited steel-erection progress. One rafter was always bolted to a column on the ground, and the two members were raised to place simultaneously.

The original plans contemplated the use of a thin cement layer on top of the corrugated roofing, but on account of the scarcity of cement and sand this feature had to be eliminated. The roofing actually in place consists of a full mop of pitch, two plies of roofing felt and tar, and one ply of finish roofing, the latter being laid in strips with a lap of 6 in. On the buildings thus far erected for the Ordnance Base Depot the roofing item alone involves the covering of an area of nearly 1,000,000 square feet.

The interior of the buildings is painted by sprays (Fig. 3), supplied with air from portable compressors, gasoline-driven. These machines also supplied air for reaming and drilling tools used in connection with the steel erection and electric wiring.

During my visit to the job a large percentage of the glazing had been finished on the shop buildings. Wire-glass is employed for the monitors, while the side-wall sash is fitted with ribbed factory glass. Like everything else entering into the work, the wire-glass was supplied from America. On such a long trip and in the reloading in France, a certain amount of rough handling was inevitable, but even those panels which are cracked are entirely serviceable, as the wire reinforcing holds the plate rigid. Sheets of glass with cracks radiating across their surfaces like spider-webs are set up in the monitors and are performing efficient service. The use of wire-glass has effected a substantial item of saving, because it has rendered unnecessary the replacement of breakage. This is not the case with the plain ribbed glass. At a time when the demand for glass in France has been increased by the bombing and long-range bombardment of cities by German airplanes and guns, it has been possible to use at the Ordnance Base practically all of the wired glazing which we brought over here, rather than go into the French market for it.

The machine tools with which the shops will be equipped include practically everything up to huge gun-barrel lathes 60 ft. long. There is demanded, therefore, a very sizeable yardage of concrete in the foundations for this equipment. The excavation is made by pick and shovel, and for the concrete a number of portable $\frac{5}{8}$-yd. mixers, such as those shown in Figs. 4 and 5, are employed. The delivery of cement and aggregate to the machines and the transporting of the concrete to the forms are handled by metal-body wheelbarrows, of which there are a great number on the job. They are employed not only for the delivery of concrete to machine-tool foundations (Fig. 5) and column footings, but also for distributing the earth fill for the floors.

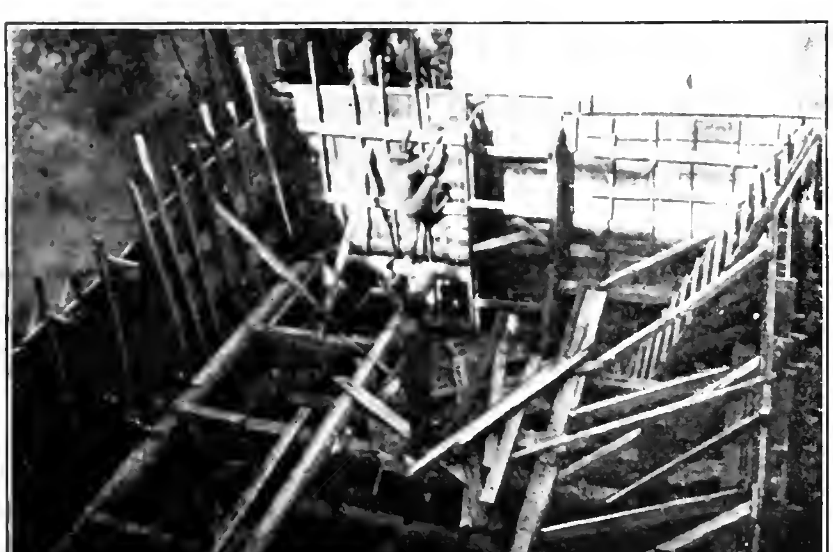

FIG. 7. WOODEN FORMS IN PLACE FOR CONCRETE LINING OF GUN-SHRINKING PIT

FIG. 8. CORRUGATED IRON SHEETS FORM INCLINED CHUTES FOR LINING GUN-SHRINKING PIT

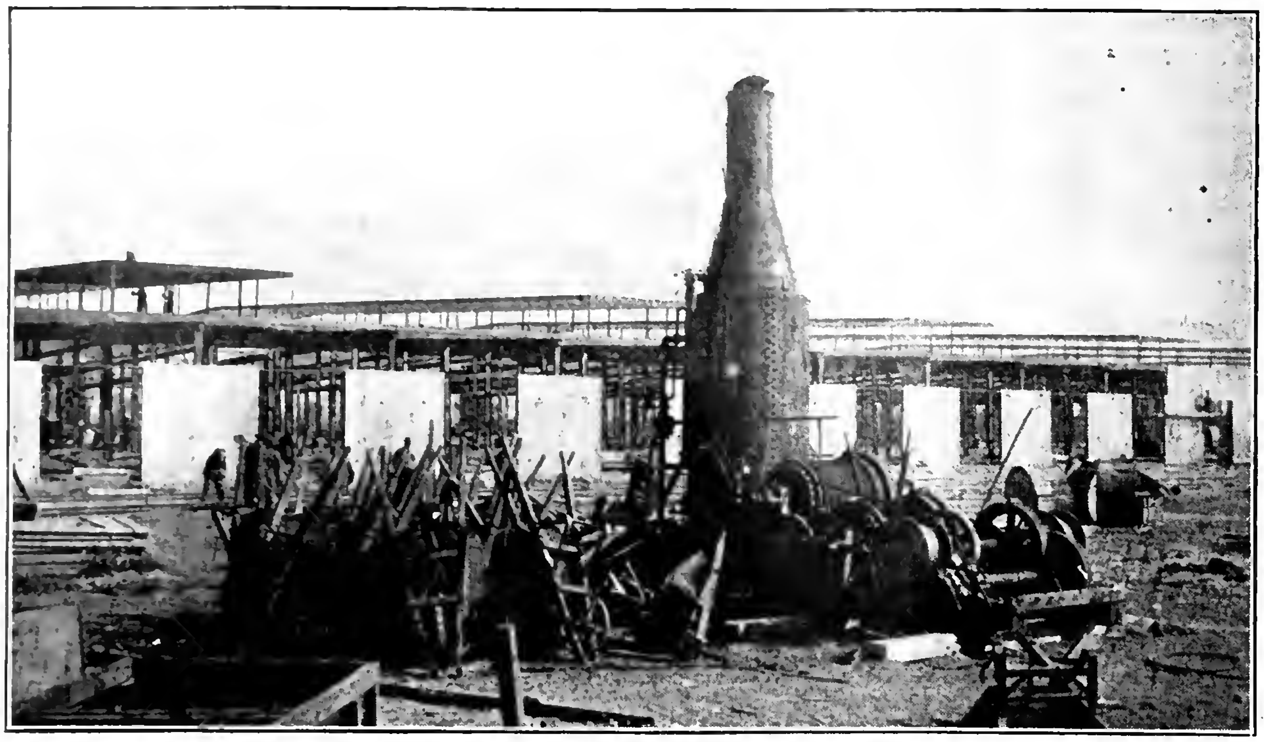

FIG. 9. IN BACKGROUND, STEEL WAREHOUSE STRUCTURE PARTIALLY SHEATHED; IN FOREGROUND, HOISTING ENGINE USED IN STEEL ERECTION

Wood is at a premium on the Ordnance Base job, and the sight of packing-cases broken up and used for concrete forms is such an old one in France now as hardly to attract attention. Practically all of the forms for the machine-tool beds are made of packing-case lumber. Another place in which this lumber is serving is in the gun-shrinking pit at one end of the gunshop. Here a rectangular excavation 20 x 35 ft. in plan and 25 ft. deep was taken out with the aid of a clamshell bucket and a crane, as shown in Fig. 6. This pit is being lined with concrete, mixed in a paving mixer. An interesting detail of the work of placing the concrete is the improvised inclined chutes shown in Fig. 8. These are merely the regular corrugated sheets used for the siding of the warehouses, and bent into the form of a trough.

The patchwork character of the framework in the shrinking-pit, due to the scarcity of lumber, is also plainly indicated in Fig. 7. The concreting of the floor of the pit was rendered difficult by a flow of underground water amounting to 600 gal. per minute. Pumps had to be installed before the concreting work could proceed. While on the subject of concreting, it is well to mention the difficulty of obtaining cement, sand and coarse aggregate. One of the superintendents told me that the job has been out of concreting materials for 10 days at a time.

Shipping Details Systematized—With the tremendous number of crates reaching France it is important, to insure prompt delivery at the right destination, that all packages be properly marked. To this matter the shipping end of the Stone & Webster organizations in the United States and in France gave particular attention. Every crate intended for the Ordnance Base Depot carries on its side a triangle and the initials "S. W." painted in black, together with a complete description of its contents.

The explicit marking aids in the routing of the crate to its proper place on the job. Initials O. B. D. in the triangle identify the crate at once as intended for the Ordnance Base Depot. The serial and package numbers aid in checking invoices; the plant and building numbers leave no doubt as to where the machine is to be installed.

For the handling and routing of Ordnance Depot material arriving in France men were stationed at every base port. Shipments leaving the United States may arrive at any one of several ports—no one knows in advance the point of landing. The method followed in checking up was substantially as follows: On receipt of a ship's manifest at a base port the representative at that place would at once communicate with his headquarters office and receive instructions as to routing of the material, for half a dozen of the ordnance buildings were set up at other sites than the main depot. The record of the material received was made in the form of a quadruplicate report. One copy of this report went to the administrative headquarters in France, two copies were sent to the job, and the fourth was retained by the checker at the docks. The two copies reaching the job were checked up against material actually delivered, one copy was retained for the job files, and the other was sent to administrative headquarters as a receipt of the shipment. On Aug. 15, 2400 carloads of material had been delivered to the base depot and 48 carloads were en route.

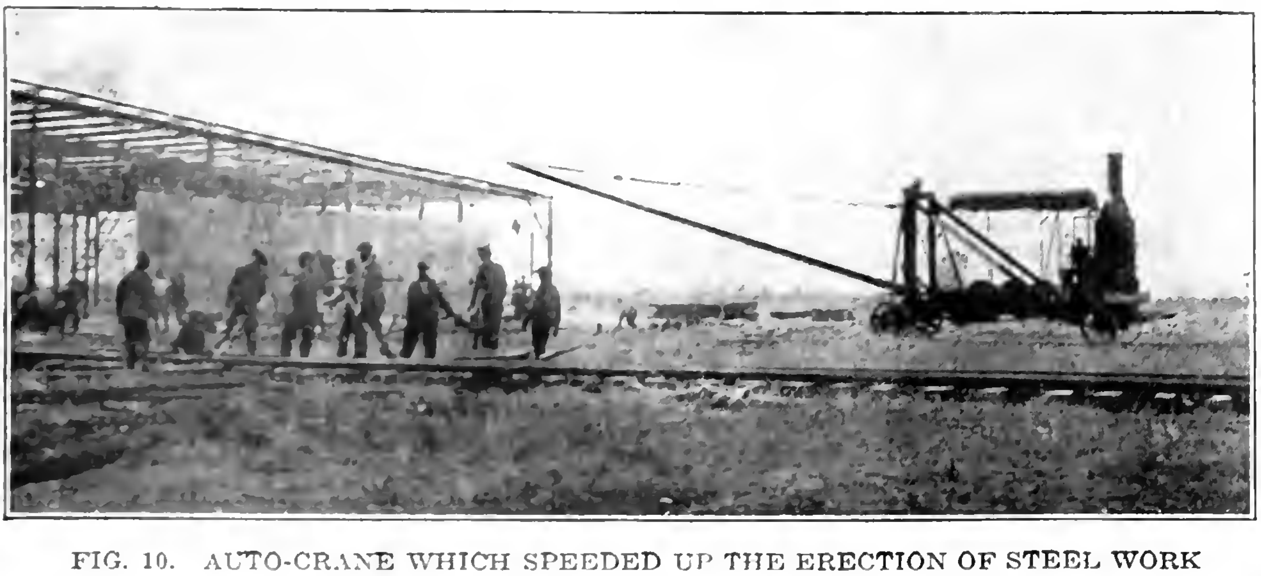

FIG. 10. AUTO-CRANE WHICH SPEEDED UP THE ERECTION OF STEEL WORK

Construction Plant—While construction plant did not arrive in time to aid in the first stages of the job, notably in building the railroad siding, and in unloading the first shipments of material, a considerable number of machines of various types was delivered later and have been responsible in large measure for the progress made. "We didn't even havea track jack when we began the railroad work," said a captain of engineers,

in telling me of the early difficulties encountered. "Mud was one of our chief enemies early last spring, and the use of wheeled vehicles for distributing material around the job was simply out of the question. Why, in walking across the site of the gun-shops the mud would build up on a fellow's boots in a broad, flat cake, so that after he had been going awhile he looked as if he had snowshoes on his feet."

The following table lists some of the more important construction plant used in building the Ordnance Base Depot:

Type of Machine	Number	Kind of Work Done
Locomotive cranes	2	Handling steel and crates
Steam shovels (¾-yd.)	2	Railway excavation
Hoisting engines	6	Steel erection and miscellaneous
Auto-cranes	2	Steel erection
Traction crane and bucket	1	Excavation of shrinking pit
Portable air compressors	4	Drilling, el work, reaming and spray painting
Stiffleg derricks (10-ton)	4	Not yet set up
Road roller	1	Rolling floors
Wheelbarrows	Several hundred	Concreting and earth moving
Concrete mixers		Concreting column footings
Pavers	4	Machine tool foundations, and lining shrinking pit
Portable (¼-yd.)	12	
Locomotives	3	Handling cars

There is an abundance of concrete mixers on the job. Those in use are serving the column footings, the machine-tool foundations and the shrinking-pit lining. The change in plans whereby concrete flooring for all of the shop and warehouse structures has been eliminated has left many of the mixers idle, and they will probably be shipped to other points in France where there is a demand for them.

For the Army all construction work at the big base depot is under the immediate direction of Major F—, commanding the 501st Engineers, which consists of four companies of about 250 men each. One of these companies, however, has been assigned to duties connected with the handling of a railroad yard some miles away. In addition, there are detachments of ordnance units, several hundred Chinese, negro labor battalions and a so-called detachment of Spanish labor. Referring to the last unit, Major F— told me that shortly after the men had arrived on the job his interpreter came into the commanding officer's barracks looking absolutely fagged out.

"Did you get things all straightened out with that Spanish outfit?" inquired the major.

"Spanish!" sputtered the interpreter; "I've checked them over, and there are fourteen different nationalities represented in that bunch. Anybody that wants my interpreter's job can have it right now."

Wages for Foreign Labor—The Spanish labor is paid from 8 to 12 francs per day and board. Chinese labor is cheaper. The Orientals receive a minimum wage of four francs daily, plus food and lodging, and in addition there is a payment of 1.50 francs per man per day made to the French for the privilege of using this labor. The Chinese are good on simple jobs involving repetition of operations. For example, in connection with some of the roof work, 50,000 pieces of wire had to be cut to a certain length and twisted to a certain form. One of these pieces was made up as a sample and turned over to a detachment of Chinese. The remaining 49,999 pieces turned out by the Chinese did not vary a hair's breadth from the original model. "They copy a thing of this sort so perfectly," said Major F—, "that you would think the job was handled by a machine."

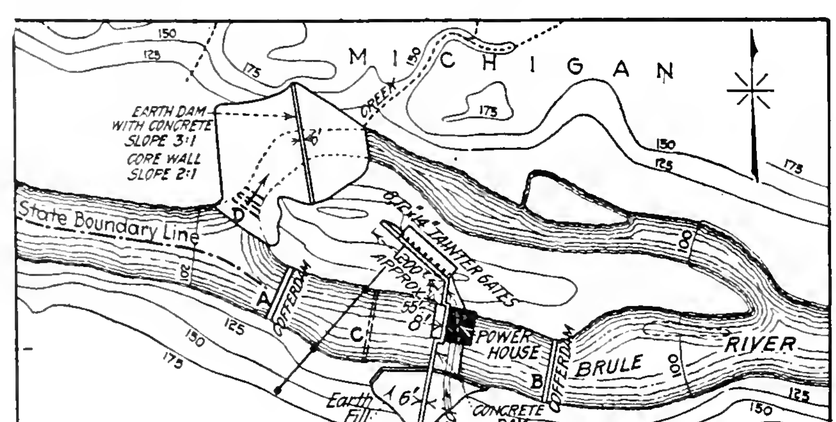
What the advent of mechanical plant on the Ordnance Base construction has meant in speeding up the job is indicated by one illustration. The steel-work for the first warehouse, 240 x 500 ft. in plan, took about three weeks. For the second, after the auto-cranes, hoists and other plant were available, the time of steel erection was about 4½ days.

Closure of Concrete Dam Completed Behind Needle Dam

Two Channels Formed by Island Simplify Problem of River Control by Cofferdams in Water-Power Plant Construction

EXCEPTIONAL use of cofferdams solved the problem of stream control in constructing the new Brule River plant of the Peninsular Power Co., in Wisconsin. Besides dams for diverting the stream and inclosing the construction operations in the stream beds, an ingenious combination of needle and flap-gate cofferdam was devised for backing up the water while making the closure of the concrete portion of the dam left open to pass the flow during construction.

Where the new power plant dams the Brule River, high banks inclose the stream and an island divides it into two channels, as shown by the map. The power



FLOW OF STREAM DIVERTED ALTERNATELY TO NORTH AND SOUTH CHANNELS

house and a short section of concrete dam close the south channel. The north channel is closed by an earth dam with a concrete core wall. On the low part of the island is a second short concrete dam and a spillway of Tainter gates.

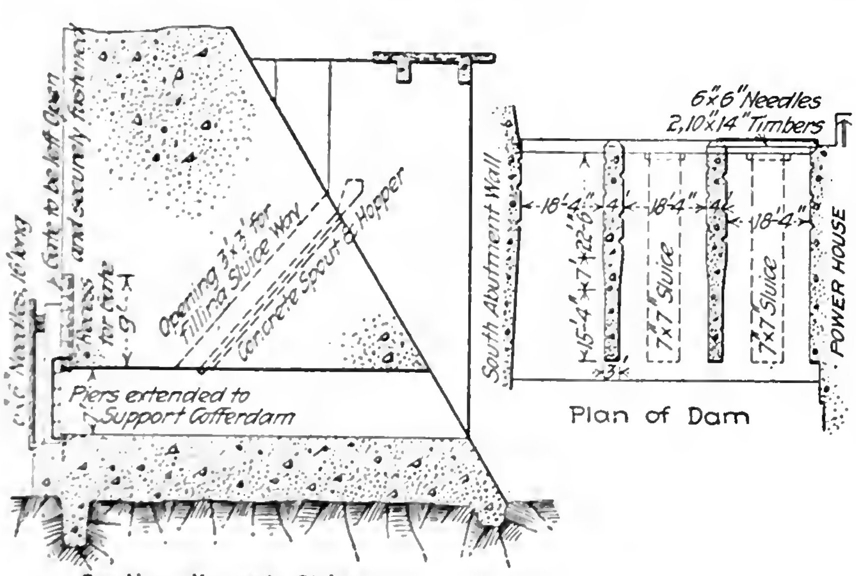
Construction was begun in June, 1917, and will be completed in 1919. In general, the plan of procedure has been: First, diversion of the stream through the north channel, and construction, to above water level, of concrete structures in the south channel; second, rediversion of the stream through the south channel, and construction of the earth dam in the north channel; third, the backing up of the south channel flow and completion of the closure of the south channel dam. Operations 1 and 2 have proceeded simultaneously, in some measure.

Work began on the south channel structures. Near the head of the island a cofferdam, A, was carried across the channel. Here the water had a maximum depth of

5 ft., and the stream bed consisted of gravel and boulders overlying bedrock. A rock-filled timber-crib dam was constructed and sheeted on the upstream side with 2-in. tongue-and-groove planks. This dam diverted the stream through the north channel. To protect the lower end of the works from back flow a second cofferdam, B, was constructed. Water here was only 2 ft. deep, and a dam of A-frames, sheeted on the downstream side with 2-in. tongue-and-groove planks, met the requirements. Dams A and B inclosed the south stream bed operations.

Seepage through the upper dam A was small, but to reduce pumping as much as possible a secondary earth-fill dam, C, was constructed about 200 ft. downstream. A fall of about 2 ft. between the upper and the lower main dams permitted a sluice, located along the south edge of the island, to carry the water ponded by the secondary dam to a discharge below dam, B. Two 4-in. diaphragm pumps then unwatered and kept dry the stream bed needed for construction.

Under the power house and south dam, bedrock lay only about a foot below stream bed. Excavation to get to sound rock was a hand-loading and dump-cart operation. Construction of the power house and of the two wings of the concrete dam followed. For the south wing of the dam only the foundations and the south abutment were completed; the dam section proper, as shown by the drawings, was left open except for two narrow diaphragms, of the section of the dam, which were built up like two piers and which divided the opening into three 18-ft. sluices for passing the stream until closure. The power house and the north wing of the dam were constructed complete. After completion of the south channel structures, as described, a cofferdam,



NEEDLE COFFERDAMS BACK UP WATER FOR FINAL CLOSURE OF THE DAM

D, was built across the north channel and the stream rediverted through the south channel and the sluices in the south wing of the concrete dam.

Excavation was next begun for the core wall of the earth-fill dam across the north channel. The core-wall trench was carried down 18 ft. below the stream bed. After the core wall was concreted, as described later, the earth fill was begun. A ¾-cu.yd. steam shovel loaded the earth in 1½-cu.yd. dump cars which traveled to and dumped into the fill.

The concrete construction included the south channel dam shown in section by the drawing; the foundations, forebay and wheel pits of the power house; the foundations and piers for the Tainter gates, the core walls and the necessary dam abutments.

All the concrete was mixed at and distributed from a plant on the south bank of the river. Here the mixers were set at an elevation about 4 ft. above the dam top. Two steam-driven mixers of 12- and 16-cu.ft. capacity, and one electrically driven, 16-cu.ft. mixer constituted the plant. Only one mixer was operated, the two others being spare units. Storage bins for gravel were constructed above the mixers and a cement house alongside them. Gravel was excavated from a bank about ½ mile from the mixing plant, and was hauled in dump wagons to an elevated road above the bins, and thence dumped into the bins. Cement from a railway at Florence, Wis., was hauled by wagons to the same elevated road, and thence chuted into the cement house.

The concrete for the lower portions of the work was chuted to a hopper at the foot of the bank. As the work progressed, the hopper was raised. Distribution from the hopper was by two-wheeled carts. Even the concrete for the core wall of the north channel dam was hauled by carts over the power-house site, dams and spillways. For winter work the concrete materials were heated by means of perforated steam pipes in the bins.

Closure of the south wing of the concrete dam was to be accomplished by backing up the water. As shown by the drawing, one of the 18-ft. openings will be closed by 6 x 6-in. needles. Behind this needle dam the gap will be filled with concrete, except for a 7 x 7-ft. sluice, which will be fitted with a wood flap-gate. The second and third gaps will be closed by similar methods, except that the third gap will be completely closed. Until the final raising of the water the two 7 x 7-ft. sluices will remain open. At that time the gates will be closed, and the sluices will be filled with concrete by means of the spout indicated on the drawing.

J. R. McDonald, Black River Falls, Wis., is general contractor for this work on a cost-plus-fixed-sum basis. Daniel W. Mead and Charles V. Seastone, Madison, Wis., are the chief engineers, the entire work being done under their supervision. They are represented on the work by A. M. Trester. O. C. Davidson, Iron Mountain, Mich., is the president of the power company, and F. E. Turneaure, Madison, Wis., is the secretary-treasurer.

Work at Head Office of Highway Department

That the routine work in the main office of a state highway department is large is shown by the report of H. Eltinge Breed, first deputy highway commissioner of New York State. This report, recently issued, covered the year 1917. Some of the work reported consisted of the following: Making 31,689 blueprints and 4643 white prints, of which 4178 were on cloth; 335 sets of highway plans on cloth, averaging 12 sheets each, 609 sets highway plans on paper, averaging 13 sheets each; 5385 prints of 500-ft. scale maps; 3000 cross-section prints; 2700 right-of-way prints; 5500 maintenance and repair prints; 6500 miscellaneous prints of forms, etc. A total of 149,504 sq.ft. of paper and cloth was used for this purpose.

Developments in the Practice of Laying and Manufacturing Paving Materials

War-time restrictions have had a marked effect upon progress in the field of pavement construction. Output has been cut to a minimum, by both Government regulations and by uncommon economic disturbances. However, the following statements, obtained at the solicitation of "Engineering News-Record" from representatives of manufacturers of various materials, indicate that there has been considerable advance in the adoption of methods heretofore considered experimental, and that economies have been fostered or forced by the abnormal conditions. It is shown that much greater attention is being paid to proper drainage, smoothness and other details of construction, and that maintenance methods are being more closely studied. Mortar-bed or other rigid construction has become practically established for all types of block pavements, superseding the old sand-cushion design. Interesting adaptations of paving materials to war purposes are also recorded.—EDITOR.

Asphalt Block Adapted to War Purposes

By Edwin J. Morrison
President, National Association of Asphalt Block Manufacturers

NOTHING notable was added during 1918 to the accepted practice in the building of streets and roads with asphalt blocks. Many Governmental restrictions confined construction to essential improvements of heavy-traffic roads where asphalt blocks were specified because of their demonstrated ability to carry heavy motor-vehicle traffic. The most interesting developments of the year were along the lines of working out labor-saving methods, in order to minimize the effects of extreme labor shortage and high wages. These efforts resulted in far-reaching improvements in methods of handling blocks, so that from the plant to the place of use, practically all hand labor has been eliminated, and mechanical devices have been designed.

A notable development of the year has been the demands of war and war industries upon the industry and the adaptation of the blocks to many military and essential war uses. Their utilization in war business has amounted to over 85% of the year's output for the company which the writer represents. The Navy Department has made extensive use of asphalt block at the New York, Boston, Philadelphia and Washington yards in flooring for storehouses, machine shops, etc., and at the great Brooklyn Navy supply base, where alone about 45,000 sq.yd. were used in flooring for storehouses, paving of loading platforms and streets around the plant, and paving connecting roadways between the buildings and the water front. These installations involved a very careful study of service conditions, in order to adapt the manufacturing formula to the production of blocks of requisite hardness, softness or malleability for special traffic and temperature conditions.

One unique problem urgently submitted to us was to produce an acid-resisting block for use in the flooring of a large submarine-battery storage building. This problem was successfully solved by the manufacture of a special block composed entirely of traprock, crushed to an unusual degree of fineness, and combined under high pressure with a processed cementing material. These blocks passed the severe tests of the Navy Department when subjected to a 25% sulphuric-acid solution.

In addition to many installations in ordnance and munition plants, the War Department selected asphalt block for extensive use in one of its most important plants—the South Brooklyn Army supply base—where more than 100,000 sq.yd. are being used in the flooring for the four piers, 1300 ft. long by 150 ft. wide; also for bridges, tunnels, loading platforms and traffic aisles.

The developments for the near future will probably be in the direction of the improvement of paving material and the design and construction of highways to carry the vastly increased motor-vehicle loads which recent military use has shown to be beyond the power of many existing highways to withstand.

A Negligible Year in Asphalt Paving

(From interviews with asphalt manufacturers)

GLOOMY prospects for new paving of every description marked the opening of the year 1918, on account of war conditions. Aside from any other features, the railroad situation was such that it seemed hopeless to figure on shipping paving materials with any degree of success at that time. Labor was extremely scarce, very high in price and in most cases inefficient; but the particular feature which affected the asphalt situation was the shortage of tank and other steamers to carry the crude asphalt from Mexico and South America and the impossibility of land transportation from other sources.

A large number of steamers carrying supplies for the American Expeditionary Forces were equipped to burn fuel oil, and it was especially desired that they should do so, owing to scarcity of coal. A great many Pacific Coast steamers which were fuel-oil burners were diverted to the European traffic, and all such steamers had to rely upon the Mexican oil for power. Consequently, the demands for oil were so great that it was necessary to make this the paramount feature in connection with the importation of Mexican asphaltic maltha.

In addition to there being a shortage of tank equipment, the importation of asphalts from South America was also greatly restricted by the action of the War Trade Board, which cut down the importation of these asphalts on account of the shortage of cargo steamers. These outstanding features, combined with the labor problem, made it a very negligible year in the construction and maintenance of asphalt pavements.

Maintenance has been the principal paving use to which asphalt has been put, and surface treatments have been used to some extent. Considerable patching has been done by "cold-patch" methods, using asphalt.

The fact that the maintenance of so many streets and roads had to be neglected, and the widespread and insistent demand for new roads and streets, would portend that the year 1919 may be a very busy one.

Status of Paving Brick in Manufacture and Use During Past Year

By Will P. Blair
Vice-President, National Paving Brick Manufacturers' Association

No DISTINCTIVE advance in the manufacture of paving brick has developed during the year. Progress is always in the mind of the manufacturer, covering two essential phases of the business: (1) Economy of production; (2) betterment of quality.

Generally considered, manufacturers do not hope for any special development which will increase the quality of paving brick. They do, however, bear in mind that care and skill must be constantly exercised, or quality will depreciate. The best known methods must be skillfully applied in each step of manufacture—preparation of the raw material, its formation, its drying and its burning—or, properly speaking, its vitrification.

In the economical phases of production, considerable hope is felt that some special saving may be achieved. Economy in fuel is a large question, to which many engineers are devoting much time. It is most important in the manufacture of paving brick, because the great proportion of expense is for the large amount of fuel consumed.

Economical handling, in both the processes of manufacture and of loading for shipment, is open to improvement. Special skill and devices, many of which have been patented, embracing almost numberless designs—all of more or less merit—have been brought into existence; but neither a particular method of fuel consumption nor any of handling has attained general approval.

In the use of paving brick throughout the year but few really new methods have been suggested. West of the Mississippi River the use of a bituminous filler is adhered to almost universally.

Throughout the Central states, the use of the sand cushion underneath the brick in connection with the use of cement filler has been almost wholly abandoned. In its place the method known as "the green-concrete-foundation method," which consists in laying the brick in the wet concrete, is extensively used. South of the Ohio River, particularly in the Gulf Coast section, also, this method is becoming popular.

Both in the Central and Eastern parts of the country there is frequently employed the type of construction known as the "sand-cement superfoundation," which consists of mixing the cement with the sand in a dry state and laying the brick thereon, after which the sand and cement is thoroughly dampened.

There has been a suggestion—in theory meeting the approval of a number of students of construction—to lay the brick upon a bituminous base or foundation. However, this method has not been tried out sufficiently.

During the past year the subject of drainage (always of frequent mention, but seldom seriously undertaken) has gained in importance. F. R. Williams, paving engineer, Cleveland, reports an interesting experience the past year. Improvement of Woodhill Road was designed for the monolithic or green-concrete-foundation type of brick pavement. The road skirts the foothills throughout the greater part of its length, so that the fall of water through the plastic soil has been the source of much trouble. Drains were laid outside of either curb and at sufficient depth to carry the water into the manholes. Cross drains discharging into these were laid under the entire base of the pavement, with sufficient fall to remove the water quickly from the subgrade. It was immediately observed, following severe downpours of rain, that the subgrade was quickly relieved of water, and the contractor was able to resume work with little loss of time due to weather.

Such advantage in construction economy was established by this drainage that contractors have installed it without cost to the city even where their specifications did not call for it. This experience not only established a construction economy, but clearly demonstrated that such a complete drainage system insured a continuous dry subgrade, and thereby the durability of the road.

Sees Development in Maintenance and Repair by Tar Products

By John S. Crandell
Consulting Engineer, General Tarvia Department, The Barrett Company

EXPERIENCE during the past year has emphasized the necessity for careful laboratory control and strict adherence to standardized methods, in the manufacture and use of paving materials. Especially has this been true of tar products. Control at the plant has been insisted on more than ever before, with the result that the output has been satisfactorily uniform. In the actual road work it has been necessary to try new methods, for the shortage of labor and its high cost have made economy obligatory. Furthermore, the restrictions placed on the highway builders by the Highways Council have caused the former to repair and maintain many miles of road that, under former conditions, would have been rebuilt. In consequence of this, patching and maintenance materials have been used to a greater extent than materials of construction.

For the repair of bituminous roads, cold patching has assumed a leading place. Tarvia-KP has been used in quantity by the various state and town highway officials. It has shown what can be done to keep roads in good condition at slight expense. Concrete roads have been repaired and kept in service by the use of Tarvia-XC; this is the material recommended by the Association of Portland Cement Manufacturers for patching and for mending cracks in concrete roads.

In actual road construction a new method has been standardized. This is the cold-penetration method, using Tarvia-B to take the place of water in the water-bound road. The results appear to have fully justified the slight increased cost of tar over water-bound macadam. The roads built by this method in Camp Douglas, Wisconsin, have carried heavy camp traffic. Enough roads of this type have been built to standardize the method of construction.

What may have been the established practice for many years in one locality may be a novelty in another. Surface treatments with Tarvia-B have been standard practice in many regions for years, but in others this past year has been the first in which they have been tried. With the increase of heavy truck and swiftly moving pleasure-car traffic, and with the scarcity of labor, the necessity of preserving existing macadam and gravel roads has been placed upon the entire country.

The greatest development looked for in the near future is the return to the tar-bound base. A number of articles have been written during the past few months on this subject, which show plainly that engineers are interested. The undisputed success of this type of foundation in many widely scattered cities points to its possibilities and offers interested engineers an opportunity to investigate. Specifications covering the materials and method of construction have been prepared and published in periodicals. The tar-bound base has been used under sheet-asphalt and block pavements.

Another development looked for is the patching of brick and the mending of the cracks in grouted brick pavements with Tarvia-XC in the same manner in which cement concrete pavements are now repaired. Many of the brick pavements that have failed could have been saved, probably, for some time, if the cracks and holes caused by local disintegration had been filled with Tarvia-XC at the time of their appearance, and before the adjacent pavement began to shatter.

Another future development expected is the treatment of wood-block pavements that bulge and heave, due to absorption of moisture. If these dried out blocks receive a treatment with a light tar, they become waterproof.

Highway Engineers Perfect Details of Concrete Road Construction

By A. N. Johnson

Consulting Highway Engineer, Portland Cement Association

Experience during the past year with heavy war traffic has demonstrated the necessity of thoroughly substantial pavements, so that thicker roads will be more generally designed and built. Concrete roads should be not less than 6 in. thick at the side and about 8 in. in the center for widths up to 20 ft. On main traveled ways, a thickness of 8 in. at the side and 10 in. at the center should be laid.

With the greatly increased use of concrete for roads, highway engineers are giving more and more attention to perfecting details of construction. There is probably no single development in the manufacture of concrete of more significance than a proper water content. An appreciation of this fact has been made possible chiefly through the exhaustive investigations carried on under the direction of Prof. D. A. Abrams of Lewis Institute, Chicago, made in coöperation with the Portland Cement Association. By controlling the water content, the strength of the concrete can be increased from 50 to 100 per cent.

It was formerly the practice to specify 1½ in. as the limiting size for the largest aggregate. It is now generally recognized that the largest aggregate may well be 2 in., and many engineers are using aggregate as large as 2½ in. It is of more importance to have clean aggregates than it is that particles of aggregate shall be of the hardest and toughest variety. In fact, it has been shown by the service rendered on many concrete roads that aggregate which is too soft for use in macadam roads does make a concrete road that will withstand without appreciable wear the heaviest motor traffic.

The importance of testing aggregates, particularly the fine aggregates, for organic impurities has received prominence in recent practice. The colorimetric test devised for this purpose can be readily made in the field, as only the most simple apparatus is required. The test is made with a 3% solution of sodium hydroxide in which the fine aggregate is shaken, the organic impurities being readily detected by the dark color of the liquid after settling. Light yellow or amber color indicates freedom from organic impurities that will injure the concrete, while a pronounced tan or light brown color indicates an amount which should not be allowed in aggregate for concrete road work.

Thoroughly mixed concrete is recognized more and more as essential to the best results, so that now practically all state specifications require not less than 1 min. of thorough mixing of all materials. The most common mix is 1:2:3, but some engineers require 1:1½:3.

Special attention has been given to the development of as perfect a surface as possible for concrete roads. Of first importance to secure this result are accurately placed and substantially built side forms, which should be rigidly held to the grade line. The roller-and-belt method of finishing has made it possible to secure a better surface than with the hand-float method. During the past year no less than 85% of various sections of concrete road work have been finished by this method, which is prescribed in many state specifications.

An improvement upon this method, and one that gives a remarkably true surface, is made by the use of a finishing machine so constructed that it automatically shapes and tamps the concrete. The machine can be reversed so that it is possible to go over the surface a number of times. This is of the highest importance, if the greatest density and strongest concrete are to result. Also, a much smaller quantity of water may be used in the mix, when finishing is done by this device, and this insures a stronger and better concrete.

Paint-Coat Method Becomes Standard Construction for Wood Block

By Walter Buehler

Chairman, Committee on Wood-Block Paving, American Wood Preservers' Association

During the past year the greatest advance made in the construction of creosoted wood block pavements has been the general adoption as a standard of the pitch paint coat method.

In January, 1918, the American Wood Preservers' Association's Committee on Wood-Block Paving submitted, as information, a specification for the laying of wood blocks directly on a smooth concrete base painted with a thin paint coat of pitch. At that time there were only a few examples of this form of construction. During 1918 more than 1,000,000 sq.yd. were laid in this way.

The principal precautions necessary to assure success, aside from the treatment of blocks, are: (1) Proper

proportioning of the concrete; (2) careful application of the paint coat; (3) proper application of the filler.

Concrete for this work should consist of aggregates so graded and proportioned as to assure a sufficient mortar content to permit of proper finishing. A mixture consisting of one part of cement, 2½ parts of sand and 5 parts of gravel or crushed stone, the gravel or crushed stone all passing a 1½-in. mesh and retained on a ¼ in., and with no intermediate sizes removed, will give satisfactory results.

A number of ways of finishing concrete have been developed. The simplest is by the use of a long handled float. The standard concrete roller-and-belt methods have also been used. E. R. Dutton, engineer of paving of Minneapolis, Minn., has developed a method which he asserts is working out successfully. It consists of a small pipe roller of about 3 in. diameter and about 15 ft. long. This roller is operated crosswise of the street on templets, consisting of 1 in. boards on edge, cut to crown of street and held vertically by specially prepared iron stakes driven into the subgrade. Whatever method is used, the important result is an even surface, but it is not necessary that it have a sidewalk finish.

Application of the pitch paint coat requires no special skill. It is important that the pitch be heated to at least 250° F. and that it be spread over the surface of the concrete in a very thin layer, not exceeding ⅛ in. thickness. The blocks should be laid after the paint coat has hardened. If possible, all paint-coated concrete should be covered with blocks each night.

To assure success, it is important that the blocks be properly filled. The pitch must be heated to a temperature of not less than 250° F. and not more than 325° F. It should be poured on the surface of thoroughly cleaned blocks and squeegeed rapidly in one direction only and should not be mopped back and forth. The ideal condition is a clean surface, with pitch filling about one-third of each joint.

Granite Block Laid on Mortar Bed and Adapted to Trunk Highways

By A. T. Rhodes
Field Engineer, Granite Paving Block Manufacturers' Association

There are several developments, both in manufacture and laying of granite blocks, which deserve the consideration of engineers and commissioners of public works—such as standardization of sizes, adoption of the mortar bed, and the recent adaptation of the blocks to trunk-line highway construction.

If any practicable method could be devised whereby paving block could be machine made, economically, this method would be adopted. When it is realized, however, that the subdivision is made from blocks as large as 1 cu.yd., and a block containing eight standard sized pavers is reduced to finished units in 90 sec., it can be seen that a skillful mechanic can make these blocks by hand much faster and more economically than could any present mechanical device requiring shifting of the blocks into various positions.

There is another condition in manufacture which would be very much improved if engineers would realize that they gain no particular advantage by sticking to their "pet" size of blocks. If blocks were standardized the producer could more readily hold a large stock of material, having confidence in the ultimate sale of any standard style. As there are schedules of sizes under which paving cutters sign annual agreements, and as any deviation from these sizes in the way of specials calls for an increased charge, a standardization of sizes to not more than three or four would give confidence to these producers and effect an economic saving.

From a construction standpoint, 3½-in. granite blocks are coming rapidly to the front as resurfacing for worn-out pavements of various types. Where these were constructed originally with good concrete bases, sufficiently low for laying, this method is proving satisfactory.

Probably the greatest change from the original construction methods, during the past few years, is the elimination of the use of peastone to hold the blocks while ramming. It is probable that more failures occur in granite paving through the use of peastone than are occasioned in any other way.

Cement-grout filler of 1 : 1 mix is unquestionably the best. In connection with this, it is found better to eliminate pargeting, or plastering, of the rails of street-railway tracks, and allow the grout to run in against the rail itself. The grout makes a much better bond with the rail, is a more substantial mixture and has been—in one instance, at least—the support of the railway iron for three years after the ties were rotted out. Where grout filler is used, a bituminous expansion joint along the curb is coming into practice.

Another change in practice is toward the mortar bed instead of the old sand cushion under the blocks. This bed should be a 1 : 3 mix, in the writer's opinion. It is laid dry and is wet down after the blocks are rammed, so as to give it a set and a bond with the cement filler.

The use of the bituminous mastic filler is more or less in its infancy, superseding the old peastone and pitch type of joint filler. It cannot be expected that it will show the durability of cement grout filler, but circumstances, such as opening the street immediately to traffic, instead of waiting six days, and giving a better footing for horses and facilitating the making of pavement cuts, make its use advisable in many cases. To obtain the best results, it must have a quality of extreme fluidity (so that it will flow readily to the bottom of the joint), a high melting point (so that it will not bleed in the hot weather) and have strong adhesiveness. This, to my mind, could be obtained best by a mixture of tar and asphalt, but producers are opposed to supplying a mixed product. The proper proportion of sand for this mastic filler is from 35 to 50 per cent. It is difficult to use a greater amount of sand without extreme care.

One of the newest developments in the matter of granite-block paving is its entrance into the field of trunk-line highway construction. With the increased cost of all other paving material, it has been found that by slight changes in the type of construction granite-block can compete for this work with most of the more permanent paving materials. The concrete base is omitted and a cement-sand bed, as described above, 1½ in. deep after ramming, is spread directly upon the prepared subgrade. The blocks are then laid and grouted. This gives a monolithic pavement which compares favorably in cost and in wearing quality with others of equal thickness.

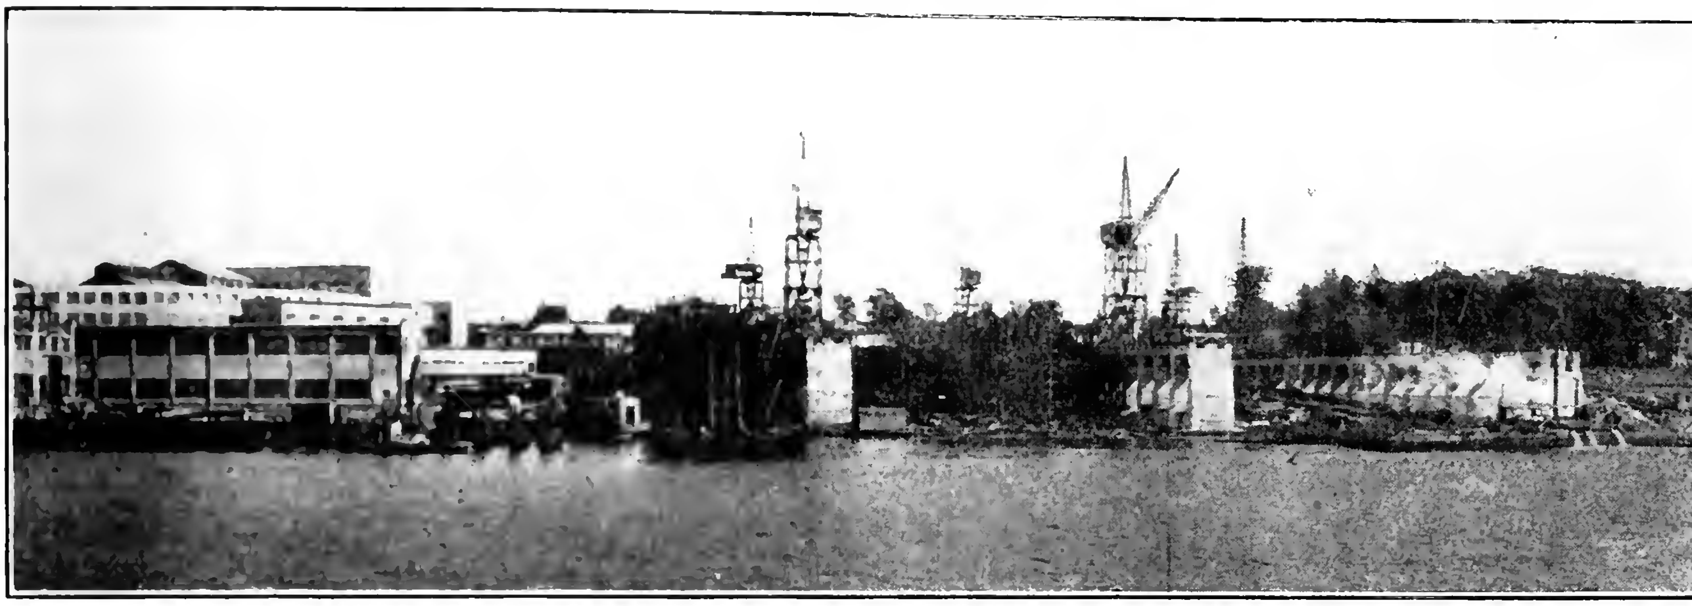
Groton Shipyard Built on Sloping Limestone Ledge

Fabricating and Storage Yards Level with Rails on Concrete Crane Ways and 22 Feet Above Concrete Shipways Set Into Rock

SIDE-HILL topography, unusual in shipyard layout, has been utilized successfully in the new yard of the Groton Iron Works at Groton, Conn., on the east shore of New London harbor. Advantage has been taken of the high land inshore to develop a two-level yard in which the material is fabricated and stored on the level of the rails of the crane runways, which themselves are some distance above the shipways. Concrete has been used extensively in the craneway and shipway construction, blacksmith shop, machine shop and fitting-out dock, though, on account of the speed necessary in erection last summer, many of the buildings have wood-frame members.

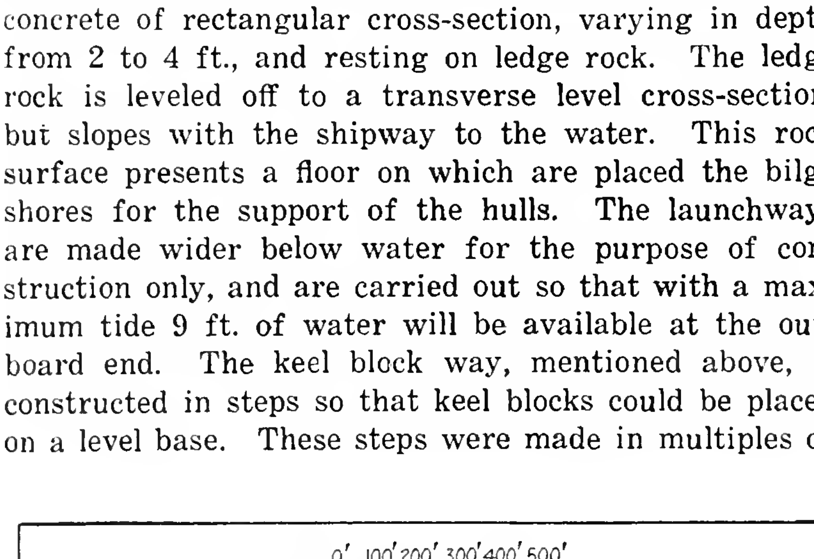
When the company took over the site in the spring of 1918, it was a country estate, similar to many of those lining the shores of New London harbor, a grassy slope underlain very close to the surface with a granite ledge sloping on a grade of about 1 in 15 down to the water. The site embraced 20 acres between the water and a main highway, and is traversed at the north end by the old main line of the New York, New Haven & Hartford R.R., which in the days before the Thames River was bridged had a ferry at this point running over to New London. The layout of the yard is shown on the accompanying drawing. Six end-launching ways were located at the south third of the yard. The northern two-thirds was left essentially on its original slope, so far as rock excavation was concerned. The tracks and buildings were laid out to accommodate themselves to the varying topography. During the construction of the yard, there was excavated approximately 15,000 yd. of ledge rock.

The ship ways are divided into three groups of two. Each group is controlled by a centrally located concrete trestle which supports two traveling cranes and a central standard-gage track for the purpose of supplying material to be placed in ships. The ways themselves slope on a grade of $\frac{5}{8}$ in. to the foot from an elevation of 24 ft. at the head of the way to $2\frac{1}{2}$ ft. at the low-water line. The grade at the top of the craneway and the assembly yard at the east of the craneway, as well as at the fabricating shop and storage yard at the north, is 42 ft. The supply tracks and the craneway tracks are placed at the above elevation. As shown on the cross-section of one of the sets of ways, a rubble-stone and concrete retaining wall, located at the head of the ways, separates the upper level from the lower level.

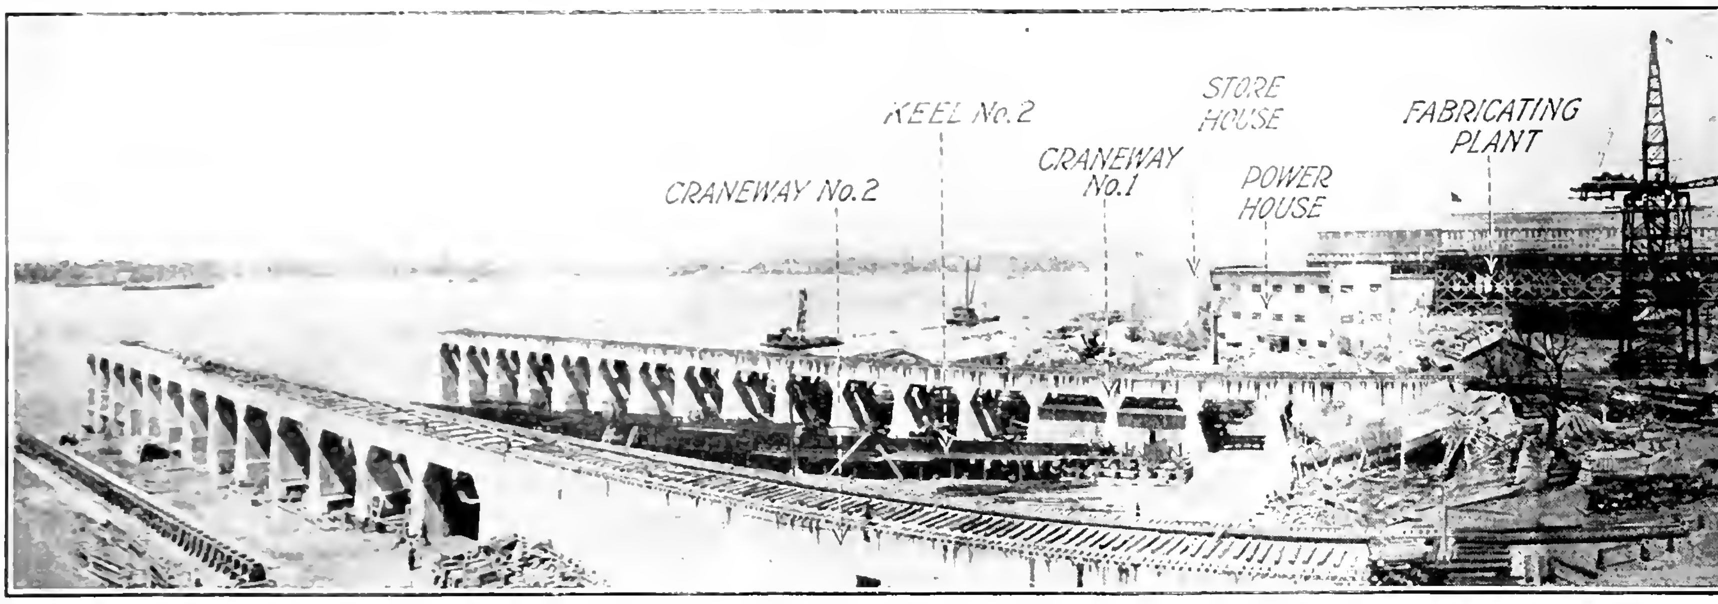


NEW SHIPYARD AT GROTON, CONN., IN OPERATION LATE LAST FALL

Each shipway consists of a central keel blockway, and two parallel launchways. All three ways are of concrete of rectangular cross-section, varying in depth from 2 to 4 ft., and resting on ledge rock. The ledge rock is leveled off to a transverse level cross-section, but slopes with the shipway to the water. This rock surface presents a floor on which are placed the bilge shores for the support of the hulls. The launchways are made wider below water for the purpose of construction only, and are carried out so that with a maximum tide 9 ft. of water will be available at the outboard end. The keel block way, mentioned above, is constructed in steps so that keel blocks could be placed on a level base. These steps were made in multiples of



GROTON IRON WORKS SHIPYARD BUILT AROUND A TWO-LEVEL LAYOUT



HIGH-LEVEL CONCRETE CRANE RUNWAYS AT CROTON YARD IN EARLY STAGE OF WORK

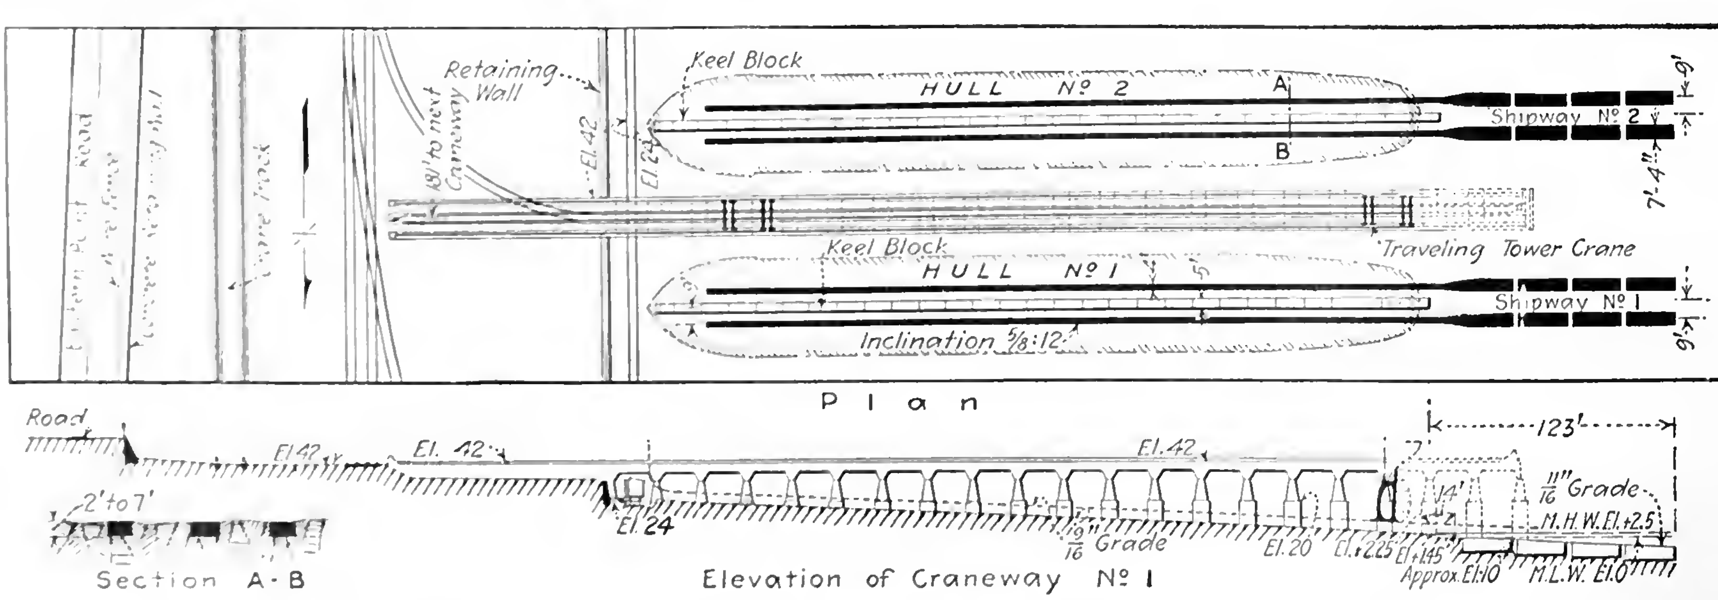
4 ft., as keel blocking is placed on 4 ft. centers. The keel block way extends but a short distance below high tide—in fact, just far enough to provide a foundation for stern post struts. The average amount of concrete in the six shipways is approximately 1200 cu.yd. In this concrete no reinforcing steel has been used, excepting as anchors, etc.

The craneways are of pier-and-girder construction, as shown in detail. The piers for the craneways are built of rubble concrete without steel, except for quill rods, etc. In some cases, rubble masonry was laid around the perimeter for the first section of the pier, and the interior filled with concrete. In all cases the piers were designed on the assumption that at least 50% of the volume could be constructed without cost over and above the cost of excessive formwork, as the great amount of granite excavation left available a ready supply of stone for this purpose. The girders, two for the crane rails and one for the central supply track, were reinforced and designed as simple beams, with the joint over the center of each support. Each of the three craneways contains approximately 3500 cu.yd. of concrete.

The traveling cranes are of Terry & Tench manufacture, and are designed for a working load of five tons at 87½ ft. and 12½ tons at 52 ft. The weight of the crane, consisting of steel frame, counterweight, machinery, etc., is approximately 107 tons. The cranes are operated by a direct current, 220-volt, 65-hp. motor for hoisting, a 25-hp. motor for swinging, and a 65-hp. motor for transit. The power is transmitted by means of two 50-lb. steel rail conductors by means of collector shoes. These conductors are carried on special framework, insulated and protected between the girders of the trestle. The eastern 100 ft. or more of each craneway is constructed on concrete walls carried down to rock—that is, where the height of the trestle was not sufficient to warrant the construction of piers and girders.

The movement of material through the yard is readily understood from the drawings. Practically everything comes in on the railroad at the north end of the yard, and is carried on standard-gage tracks, and stored in racks near the entrance. These racks are so constructed with concrete bases and steel uprights that the unfabricated material may be placed in storage, according to size and thickness, and on edge so that it can be removed with a minimum of labor when any particular section is required. Material requiring shopwork then proceeds on standard-gage tracks to the fabricating shop, where it is fabricated and sent to the storage yard in the rear of the craneways, or diverted to the machine shop, blacksmith shop, pipe shop, or fitting-out dock, as the case may require.

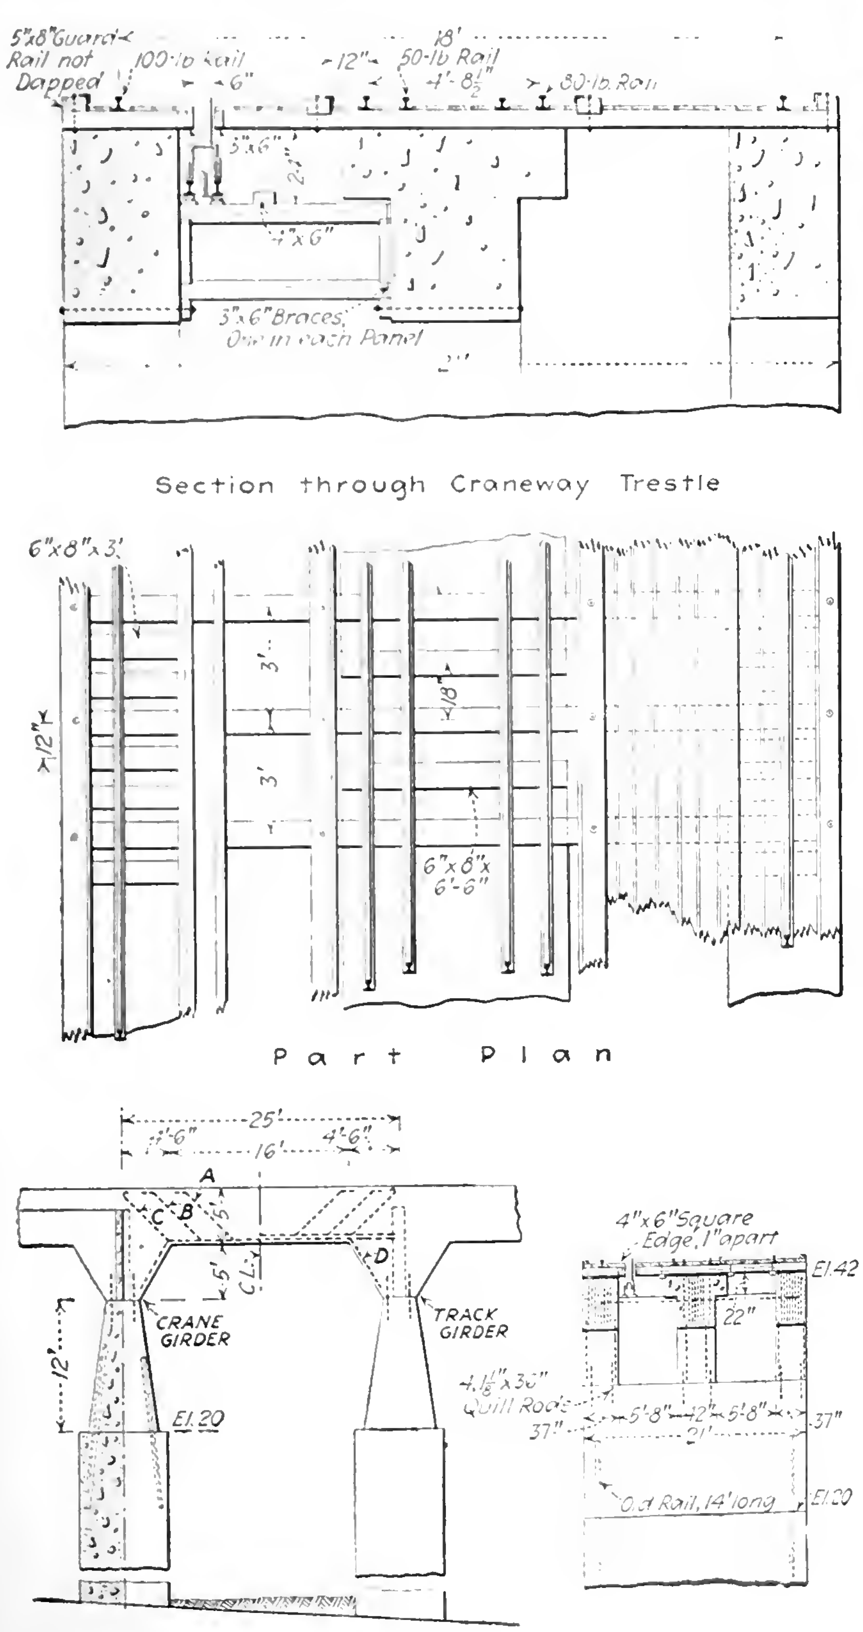
A large part of the assembling of structural parts is carried on in the inter-track space, adjoining the south side of the fabricating shop and east of the craneways, which is called the "assembly yard." It has been found to be more economical to assemble boilers, engines, condensers, channel foundations, shaft channels, bulk-



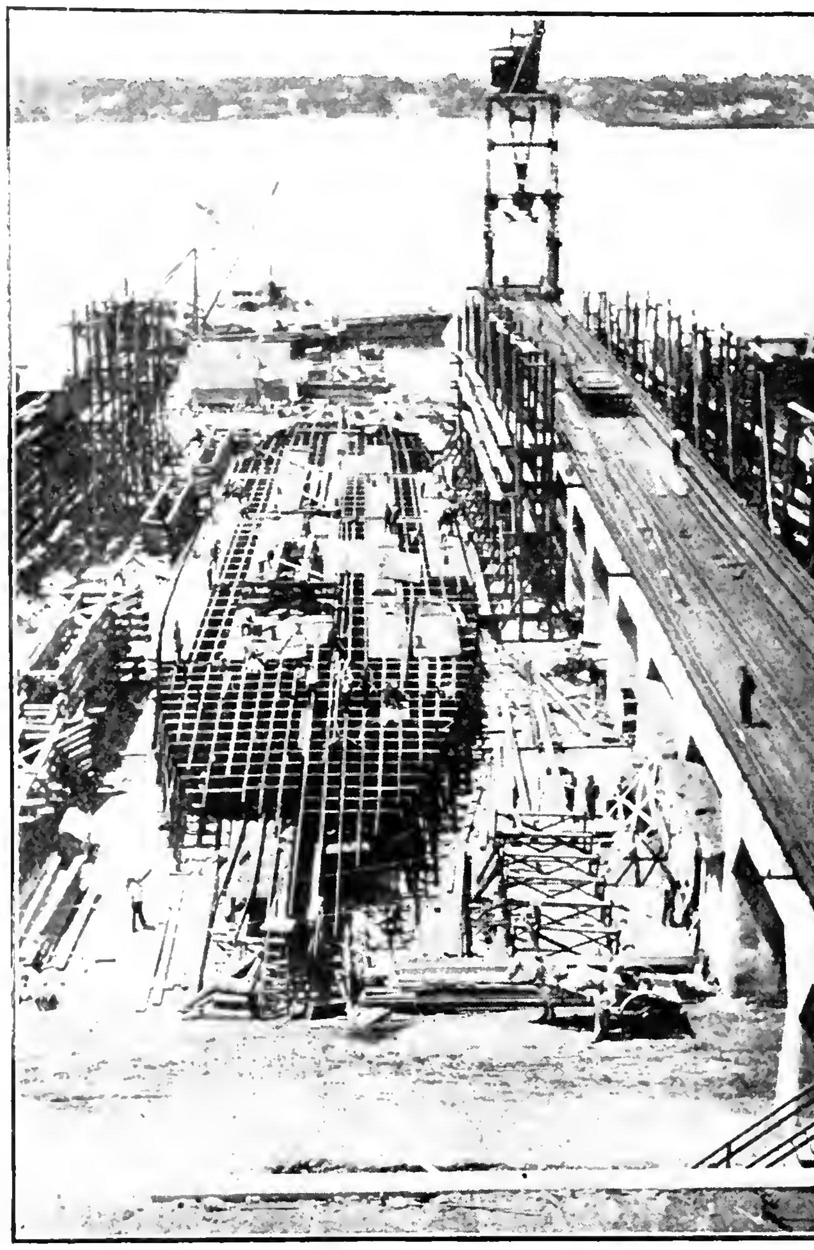
CONCRETE SHIPWAYS SET IN LEDGE ROCK AND CONCRETE CRANE RUNWAYS AT HIGH LEVEL

heads, funnels, uptakes, skylights, fantails, deck houses, floors, girders, pillars, brackets, etc., in this assembly yard, and transport them within reach of the traveling cranes by locomotive cranes. There, by means of an equalizing bar, structural units weighing upward of 20 tons have been placed by two traveling cranes. In the assembly yard, there is being constructed a craneway for a Terry & Tench crane similar in design to those mentioned. This will be used exclusively for assorting and assembling all the structural units mentioned above.

Operating in the yard, on the standard-gage tracks, are four locomotive cranes, one 35-ton crane, and three 20-ton cranes. These cranes are used in all parts of the yard, primarily for the purpose of unloading steel from cars and placing it in the plate racks, also coöperating with the traveling cranes in placing fabricated material in the hulls. The traveling cranes are so designed that material on cars can be pushed out onto the craneways under them; and, also, the locomotive cranes mentioned above can, when the case requires, be operated on the craneway in conjunction with the traveling cranes.



DETAILS OF CONCRETE TRESTLE AT SHIPYARD OF GROTON IRON WORKS



LEVEL ROCK WAY PERMITS STORAGE OF MATERIAL ALONGSIDE HULL

The main entrance track extends the entire length of the yard, east of the store house and power house, and east of the craneways. A turnout taken off near the north entrance extends to the west of the store house and power house and under the craneways at an elevation of approximately 21. From this track a turnout to the left extends north, and leads to the machine shop, carpenter shop, and fitting-out dock by means of sidings. The above track, extending west of the power house and under the craneways, is of great value for the purpose of transporting material from the machine shop, blacksmith shop, or carpenter shop to the ships before launching. This does not interfere in any way with the work in the fabricating shop or assembly yard. This track is paralleled by a roadway for the use of motor trucks, to accommodate the relatively small amount of material received in this manner.

In addition to the railroad entrance to the yard, there is a fitting-out dock, with a deep-water approach, over which material may be brought in by water. Roads have been built throughout the yard to facilitate motor-truck delivery, both from the main highway and from the dock. Keels have been laid on each of the six ways, and construction is going forward on each hull.

E. A. Morse is president of the Groton Iron Works, and E. O. Cutler vice-president and manager. The layout arrangement and equipment of the yard have

been personally directed by Mr. Cutler. The construction work has been done during the past 16 months, partly by contract, and partly on force account. The F. T. Ley Co., Springfield, Mass., constructed a section of the fabricating shop and one craneway. The Raymond Concrete Pile Co., New York, constructed the outboard launch ways. The T. A. Scott Co., New London, constructed the fitting-out dock. The remainder of the work was done by force account. G. L. Bilderbeck has been the construction engineer in charge of the structural design from the beginning of the plant construction. Arthur Jackson has been superintendent of construction in charge of the greater part of the force-account work.

Engineering Educators' Opinions Reflect Past and Predict Future Conditions

This is the second installment (the first appeared in "Engineering News-Record" of Jan. 2, p. 41) of replies to the following questions:

1. What was the influence of the Students' Army Training Corps upon the engineering colleges? Did the experience affect the educator's viewpoint, and if so, how?

2. Will the return to peace mean a return to pre-war courses without essential modification? If not, just what changes are contemplated? What considerations determined these changes?

3. Have you embodied in your plans for after-war courses any of the suggested solutions brought out by Dr. Mann in his "Study of Engineering Education"? (See "Engineering News-Record" of Oct. 24, p. 782). If so, just how are they to be applied?

4. What is your estimate of the new needs and opportunities in engineering education developed as a result of the war? How can they best be met?

Cornell Believes in Military Training, in Spite of S. A. T. C.

By E. E. Haskell

Dean of the College of Civil Engineering, Cornell University, Ithaca, N. Y.

The experience with the S. A. T. C. at Cornell was rendered unsatisfactory by the actions of younger officers, and the fact that orders to the military instructors and to academic authorities were not in duplicate, resulting in confusion and conflicts in student hours. The general feeling in regard to the work of the corps was expressed when the faculty voted unanimously to refuse the opportunity for continuing the training to the end of the present year. Nevertheless, there is still a strong feeling that military training, properly coördinated with academic work as it has been administered here for freshmen and sophomores ever since the University was established as a land-grant state institution, is a very essential part of the young men's training. Indeed, President Schurman hopes to see at Cornell University regular military and athletic training for all students for a period of not less than one hour for five afternoons of the week, with intra-mural competition between class and class, college and college, and other existing units.

The Navy unit, about 350 men, was administered successfully, but the Army unit, about 1200 men, accomplished relatively little academic work. Study facilities were inadequate, and officers monopolized the time in the evenings which should have been devoted to preparation for class work. In reply to the four specific questions which you submit I would say:

1. In view of the unsatisfactory nature of the experience with the S. A. T. C., there has apparently been no definite influence on the engineering college here.

2. We are returning to our pre-war courses on Dec. 30, and are planning to extend the third term into the summer, probably for a period of eight weeks beginning July 1. A faculty committee is considering changes already debated before the war, but no definite lessons from the war experience have yet been discussed. Last spring the trustees of the university decided in favor of the principle of consolidation of the several existing engineering departments into one department of engineering education.

3. Dr. Mann's report is being used, with other sources, for determining modifications of the present courses. Professor Jacoby is strongly in favor of the idea of making the academic work relate itself closely to practical engineering. In fact, he has for years used in his classroom work a specific problem method, with topics written out on cards. This method was extended recently to include definite questions for classroom discussion, also stated on cards. Since the co-operative courses are impracticable, it is contemplated to have students use the summer vacations for work in the fields in which they are most interested. He urges the selection of teachers who have had practical experience, and also the necessity for providing them with courses in educational psychology. The simultaneous use of both objective tests and examinations is favored. It is hoped to reduce the differentiation between courses in the freshman year, and a line may be drawn

between the sophomore and the junior years in order to insure the success in their specialties of those students who continue. A course designed to show the relation of engineering to industrial organization is contemplated. The courses in physics, mechanics and mathematics should be given by teachers who know engineering.

Stevens Institute Going Back to Pre-War Conditions

By Alexander C. Humphreys
President, Stevens Institute of Technology, Hoboken, N. J.

REPLYING to your letter of inquiry, the situation has not yet so cleared up as to enable me to express *final* opinions as to the workings and influence of the S. A. T. C. on the educational life of the United States.

1. We have to recognize that the S. A. T. C. was not given full opportunity to demonstrate its positive influence for good.

2. As far as Stevens Institute of Technology is concerned, I see no reason for not returning as rapidly and completely as possible to our pre-war conditions.

3. I am unable to find in Dr. Mann's survey anything that would be of particular value to *us*. Here we have to bear in mind that our course of instruction is a fairly harmonious blend of theory and practice. With us "the proof of the pudding is in the eating."

4. The war has emphasized the value of engineering education, as indicated in my answer to the third question.

In general, the S. A. T. C., as exemplified in the Army section, was sadly handicapped by Washington red tape. For this the Army officers assigned to Stevens were in no way responsible. The operations of the Navy unit were, by comparison, free from this disorganizing red tape influence. I give my views based upon the operations and results as they *now* appear to me.

I was and am in favor of a certain amount of military training for engineer students. I regret that the Army section of the S. A. T. C. has not helped to confirm me in this belief.

Need for Broader Training Seen as Result of War Experience

By William G. Raymond
Dean of the College of Applied Science, University of Iowa, Iowa City, Iowa

I AM very sorry that the S. A. T. C. was discontinued, for while it was a dismal failure while it lasted, it was improving and under modified administration I believe would have been tremendously successful. Answering your questions as best I can with the limited time available for their consideration, I would say:

1. The S. A. T. C. tremendously increased attendance in engineering colleges, but with a temporary increase, much of which will be lost with the close of the organization. I am not sure that the experience affected the educator's viewpoint at all. I find it difficult here to disassociate the effect of the S. A. T. C. and the general effect of the war, which, it seems to me, did affect the educator's viewpoint in that the necessity for a broader training in economics, sociology, accounting, etc., was made manifest.

2. I think this question is answered under No. 1. In our institution we shall get back to pre-war courses with some modifications, the nature of which cannot be definitely determined now, but which will be in line with the suggestion in the answer to question 1.

3. I have not studied sufficiently Dr. Mann's report to say just what effect it will have. We shall not make any attempt to adopt the so-called Cincinnati plan, the good points of which we recognize, but which does not appeal to us as at all desirable for universal application.

4. I think the first part of this question is answered under No. 1; the second part, I suspect, remains to be answered. My own judgment is that professional engineering courses should be based on courses in arts; that the engineeer of tomorrow must have a breadth of education at least equivalent to that of the lawyer or physician.

Columbia University Returning to Former Six-Year Course

By George B. Pegram
Dean of the School of Mines, Engineering and Chemistry, Columbia University, New York

I REPLY as follows on the points suggested in your questionnaire:

1. No useful comment can be made on the influence of the S. A. T. C. on engineering schools without distinguishing between the conception on the one hand and the execution on the other hand. The conception was good, and in a similar emergency we should gladly see it adopted again without any notable change. In actual execution, the S. A. T. C. began by greatly demoralizing the work of our engineering students, but thereafter improved steadily until a fairly satisfactory condition prevailed. The military administration could not suddenly furnish an organization to handle efficiently its side of the educational undertaking. Yet the war has afforded a great object lesson in the astonishing rate at which students can learn under a compelling incentive and inspiration.

Our university committee on admissions made good use of the opportunity presented by the excess of student applicants over accommodations, to make its selections partly on the basis of special tests of mental alertness and of ratings on outstanding personal qualities. The mental alertness tests were prepared by Prof. A. H. Thorndyke on the lines of his tests as applied to Army aviation candidates. The work of the men admitted indicates that these tests were valuable. In this matter of admission requirements it is quite probable that the S. A. T. C. experience will change somewhat our educational viewpoint.

2. We are now returning to pre-war courses without essential changes. Prior to the war we had established three-year professional courses based on admission requirements equivalent to three years of college work, to include mathematics, physics and chemistry, besides the usual college courses in the humanities. This brings these schools into line with our other professional schools of law and medicine. We believe that the emphasis, so evident in the selection of men in the war, on the adaptability that comes from breadth of fundamental training, as contrasted with mere technical expertness, will lead an increasing number of the more able and ambitious students to take up the study of

engineering on the foundation of a sound general and scientific education.

3. We shall find the interesting and suggestive report of Professor Mann a definite stimulus to research in engineering education. At present we are partly in agreement and partly in disagreement with his interpretations.

4. The immediate new needs and opportunities appear to be at the two ends of the scale of technical education. Vocational education should receive a great stimulus. That ship riveters can be trained in two weeks and that bent-shouldered tailors can rapidly become blacksmiths of marked skill, means broader prospects for workers in general, and with the development of schools this vocational education will lead into the elementary types of engineering. The middle ground is well covered by our present engineering schools. Beyond this there is sure to be, on account of the wider outlook of our industries, an increased demand for young men of broader training than the engineering graduate now has. We are trying at Columbia in one way to produce these men, other schools are going about it in other ways, but the product must be had if we are to develop the possibilities of our future in productive achievement.

California Experience Unsatisfactory

By C. Derleth, Jr.
Dean of the College of Civil Engineering, University of California, Berkeley, Cal.

IN MY judgment the influence of the S. A. T. C. upon the engineering colleges was unsatisfactory. Had the war continued the students would have suffered so far as purely engineering instruction is concerned. I believe that the aims of a military school are distinct from those of a civilian engineering institution; the two cannot effectively blend unless one is made decidedly subordinate. The best way to train doctors, engineers and technical chemists for Government service in time of war consists in first educating properly qualified men solely for these respective professions. In each case the course should not be less than three and preferably four years.

When these men have satisfactorily completed a course in medicine, engineering or chemistry, they should then become candidates for Army or Navy service. From these graduate groups men should be selected for military and naval training, but the amount of war training should be a minimum.

In the S. A. T. C. program it was intended to give intensive instruction whereby engineering students in two years would receive the fundamentals that heretofore had comprised a course extending over four years. It is my judgment that such intensive training mixed with military instruction and drill cannot be made effective. There is a limit beyond which the student cannot be driven. Sound growth is always slow growth.

I hope that with the return of peace engineering schools will revert largely to pre-war courses, with only a minimum of modification. Changes are necessary in our engineering curricula to meet new conditions, but these changes must be gradually and judiciously introduced. We must experiment to decide to what extent such subjects as physics and mathematics may be combined effectively with engineering applications, so that the student may study physical and mathematical principles at the same time that he is applying these principles to engineering problems. I think it would be a mistake to carry the combination to an extreme. In the beginning the student must study fundamental principles alone; the complex applications can only be attacked after the student has reached a considerable maturity.

During the past decade engineering schools have been unduly differentiating engineering courses. Too many special curricula confuse the student and tempt him to narrow his fundamental training. I hope that during the next few years our schools will limit the number of different courses offered.

Johns Hopkins University Plans Closer Relation to Practice

By C. J. Tilden
Professor of Civil Engineering, Johns Hopkins University, Baltimore, Md.

THAT at heart America is not a militaristic nation has been rather clearly shown by the experience with the S. A. T. C. During the two and a half months of the S. A. T. C. there was a great deal of friction between the military and the academic authorities in carrying out the requirements issued by the War Department. Educators, realizing the importance of the task under existing war conditions, adapted themselves and their courses to the needs of the Government, only to find that they were materially hampered by the large number of none-too-willing students and by the self-importance and officiousness of half-trained immature youngsters who had been commissioned second lieutenants. A large part of the student body was not of the usual college caliber, and found difficulty in keeping up with the many things demanded of them.

Conditions at the Johns Hopkins University were better than at many other institutions. The question of attendance on classes was settled early by an order of the military authority that the academic work was an essential part of the military training, and that purely military functions must not be allowed to interfere with it. With the chance of fighting in France taken from them, however, there is the almost universal desire on the part of the students to get out of uniform and drop the military training.

The S. A. T. C. of itself will probably have little permanent influence upon the engineering curriculum. The courses in engineering were greatly modified and made more intensive during the emergency, the program put out by the Education Committee of the War Department having been adopted practically in its entirety. This is not at all satisfactory, however, as a permanent basis, and will be relegated to the scrap heap just as rapidly as the transition can be made.

Nevertheless, many modifications of the pre-war courses are being seriously considered and will probably be adopted. In view of General Black's strong emphasis on the need for more training in descriptive geometry, the number of hours devoted to this subject will be increased, with more attention to practical

applications. The study of Spanish instead of German will be encouraged, in order to meet the demand of growing opportunities in South America. Coöperative courses, such as those offered at the University of Cincinnati, are being planned by the mechanical engineering department, and the idea receives a favorable response from industries in Baltimore. There is a new and vital need for trained organizers, and courses must be worked out to develop men to meet the practical requirements for quantity production, which will be paramount in the next few years.

Dr. Mann has given valuable suggestions in his "Study of Engineering Education." One result of the study of this report is that more emphasis will probably be put on the "project" system in teaching. It is hoped to develop this idea along the lines of the architectural problem in design or construction, with its carefully worked out schedule or program of requirements. In some ways this method is, of course, similar to the "case" system which has proved so successful in law schools.

Many Consider Experience as Disastrous

By Anson Marston
Dean of Engineering, Iowa State College, Ames, Iowa.

As I HAVE just returned from continuous service as lieutenant colonel of engineers in the Army since July, 1917, I have had no direct experience with the S. A. T. C. However, I have had opportunity to obtain personally the views of a considerable number of representatives of the principal engineering schools of the country, as well as to observe the situation at this institution. I would answer your questions as follows:

1. The experience with the S. A. T. C. at the engineering colleges has been little short of disastrous. Its effect has been to arouse—for the moment, at least—intense opposition to everything military. This feeling is so widespread among the patrons of the colleges as well as the college authorities that I fear it may have a disastrous effect upon the decision of the country as to the adoption of universal military training, which I personally favor.

2. The return to peace conditions will not mean a probable return to pre-war courses without modification. The effect of the war has been to disrupt the colleges completely. The authorities propose to take advantage of this situation to make desirable improvements, many of which they have been debating for years previous to the war. Changes will be decided upon between now and the opening of the next college year.

3. As to the "suggested solutions" by Dr. Mann in his report, they are under consideration, with other possible improvements, but nothing is finally decided as yet.

4. Post-war conditions will call for much bigger and broader engineers. This country is now a world power, and must extend her manufacturing, shipping, and financial interests all over the world. This will demand engineers of the biggest caliber and broadest training. Nevertheless, I feel that general engineering education, in meeting the new conditions, will be simplified rather than made more complex. It is so manifestly impossible to train every engineer in a predetermined specialty which will meet the demands upon him in his professional work that it seems to me probable that we must give the engineer a very thorough and broad training, and provide special schools of high technical character to which practicing engineers may come back for special training after they have determined their specialty by actual experience.

Princeton May Return to Four-Year Course

By F. H. Constant
Head of the Civil Engineering Department, Princeton University, Princeton, N. J.

IT IS rather early to answer your four searching questions upon engineering education, but we are giving the subject careful consideration.

1. Academically, the influence of the S. A. T. C. was negative. It is too early to learn what permanent influence military discipline has had upon the student mind, but it has at least been shown that the student is capable of much more intensive effort than he was encouraged to make in the past. The colleges, on the other hand, are awakened to a new conception of service. There is no reason why any man should not be permitted to pursue courses in college for which he is prepared, whether they lead to a degree or not.

2. We shall continue the three-year course for sophomores and juniors, including a nine weeks' term next summer. We may return to the four-year course for the present freshman and subsequent classes.

3. We are making a careful study of Dr. Mann's report, and may embody some of his suggested solutions in our plans. In particular, should we return to the four-year course it will be with the expectation that some system of coöperation with the engineering industries during the vacations can be put into effect. This would be the most potent reason for returning to the four-year course.

4. The war has developed a greater appreciation of the value of an engineering education. The engineering schools will undoubtedly have more students than ever before. It is the duty of these schools to keep in closest touch with the new needs created by the after-war conditions, in order that they may fulfill their highest service at this time.

Experience at Northwestern Emphasized Value of Discipline

By John F. Hayford
Director of the College of Engineering, Northwestern University, Evanston, Ill.

THE short experience of the colleges of engineering of the United States with the S. A. T. C. was an incomplete experiment, conducted under circumstances extremely unfavorable to educational success, and brought to an untimely end by the abject surrender of the Germans.

That experiment has started new lines of thought in the minds of engineeering educators, and has greatly increased the vigor with which all suggestions for improvement are studied. It has furnished suggestions only, not solutions—and some of the suggestions are clearly negative, indicating methods to be avoided.

The experiment, and to a much greater extent the whole war experience, have put forward two old ideas so strongly and clearly that improvement is reasonably sure to follow. The ideas are (1) that strong motivation leads to rapid and permanent progress on the part of the learner, and (2) that discipline leads to better performance of the whole man, including his brain.

The embryo officer in a training camp, with a clear picture in his mind of the part which it might become possible for him to take in the greatest single piece of work civilized people have yet undertaken, was so motivated that he learned at a rate that was astonishing, and later performed accordingly if the opportunity came to him. How can we secure some considerable fraction of such a motivation in our students of engineering? It must be secured, if that is possible. Can it be secured in part by showing the student early in his college career what engineering is, how essential it is to our present civilization, and how the apparently abstract parts of his early studies—in mathematics and physics, for example—are related to his possible success as an engineer?

Discipline which leads each man to coöperate with every other man in the group in such a way as to secure the maximum effectiveness of the group in accomplishing the purposes which are common to all also leads to development of the individual, including his brain, and even that indefinable part of him which gives courage, initiative and automatic habits which make hm a better man. Discipline is objectively most highly developed in the military form, and its direct effects are most obvious.

The war has emphasized the need of more and better engineering education rather than of a radically different engineering education.

It is too soon to expect the conclusions of the Mann report to be embodied in action. But, just as the valuable, permanent effects of the war on the methods of engineering education are still in the future, but sure to come, so also are the similar effects from the Mann report.

No Definite Changes Yet Decided Upon at New York University

By Charles H. Snow

Dean of the School of Applied Science, New York University, New York City

IT SHOULD be remembered that the S. A. T. C. is made up of two parts: Sections A and B, otherwise known as the academics and the vocationals. It seems to me that when commenting unfavorably, as many do, upon the work of the S. A. T. C. the tendency is to forget the participation of Section B. We regarded the work of the New York University Section B as very successful.

1. There was no constructive influence exerted by Section A upon the work of the School of Applied Science of New York University. The experience with Section B has intensified the feeling of many that certain men may not learn at all readily from books, and yet learn with surprising readiness "by doing."

2. I do not think that the return to peace will mean a return to pre-war courses without essential modifications, but I cannot yet tell what the changes here will be. Thus far it is a case of "we don't know where we are going, but we are on the way."

3. We have not yet embodied in our plans any of the suggested solutions brought out by Dr. Mann in his admirable paper. The experience is too recent; the matter is too important for quick action. We shall conclude this year on last year's program, save that the spring term will continue over into the summer. Changes will be announced for next autumn.

4. The importance of the engineer and his education has been greatly increased by the war. To say the least, this importance will not be diminished by the reconstruction period. The field suggested by your question is very large. At this writing, I can make no other direct reply than to say that the new needs and opportunities in engineering and engineering education developed as a result of the war will be very great indeed; I cannot detail.

Minnesota to Modify Surveying Course

By John R. Allen

Dean of the College of Engineering and Architecture, University of Minnesota, Minneapolis, Minn.

ANSWERING your questionnaire in regard to the effect of the S. A. T. C. at the University of Minnesota, I would say:

1. In the collegiate section of the S. A. T. C., we conducted our surveying classes all day long from 9:30 a.m. to 4:30 p.m., the students eating their luncheons in the field. This method we found very effective and satisfactory, and we shall probably continue it, although we have never done it before. This is the only class in the college which was better conducted during the S. A. T. C. than in the ordinary period.

2. There will be no substantial changes in the courses taught our students, as engineering is just the same now as it was before the war.

3. Dr. Mann's suggestions in his report were in most cases not new, and had already been considered in most engineering schools. We are making some changes in the teaching of mathematics, as we have added laboratory hours to these courses. We are also making some changes in the teaching of mechanics and physics. These changes were contemplated, however, before the publication of Dr. Mann's report.

4. I believe the opportunities for engineering education and for the engineer will be greater than before the war, due to the prominence that has been given to engineering during the war. I do not believe the needs in the engineering profession will be substantially different after the war than they were before.

Harvard Sees Need for Fundamentals

By H. J. Hughes

Professor of Civil Engineering, Harvard University Engineering School, Cambridge, Mass.

YOUR questionnaire has been referred to me for reply. The absence of many of our staff makes it impossible to give you anything but a personal opinion, which follows:

1. I am convinced of the folly of attempting to make students do the impossible, and the importance of suitable methods of selecting men for certain duties was

forcibly shown here. I have long believed that the entrance requirements now in vogue are defective, yet the recent experience has demonstrated their merits. Students in the S. A. T. C. showed distinctly less ability than our average, in spite of the fact that much of the work was less academic than usual. The best thing about the S. A. T. C. was the fine enthusiasm shown by many of the boys for any work whatever when they thought it brought them nearer active service in the war.

2. A return to peace will probably not mean a reversion to pre-war courses without essential modification, but the changes are likely to be gradual. The S. A. T. C. did not last long enough to upset traditions, and in framing its engineering programs a great opportunity to discourage needless differentiation was lost. It seems likely that certain methods of intensive training used successfully in the officers' training camps will be continued. More emphasis will probably be placed upon fundamental subjects, less upon temporary standard practices.

3. This school is being reorganized as the result of a court decision to the effect that a coöperative agreement made with the Massachusetts Institute of Technology is illegal (see *Engineering News-Record* of Dec. 26, 1918, p. 1198). The present year will be chiefly devoted to meeting the varied needs of students returning from service. Dr. Mann's report is of particular interest to us, but it is too early to say what solutions suggested by him will be embodied in our courses. Our students will have opportunities to take courses in the college, in the business school, and in other departments of science. We mean to plan for specific coöperation with the industries at some time and in some way over a considerable part of our programs. We expect to study the Cincinnati plan as an outstanding, successful experiment.

4. The new needs appear to arise from increasing demands for young engineers who are thoroughly grounded in science and capable of solving new problems at first-hand. The importance of training in fundamentals has been emphasized for years, and yet some of the most glaring defects in engineering education continue to be perpetuated. Most engineers realize that the fourth year and often the third are padded with so-called professional subjects, superficial in themselves, and valuable chiefly as advertising matter. Now the schools have an opportunity to face the facts honestly, to break with old habits and prejudices, and to provide the kind of training we know to be needed.

Unusual Features in Willamette River Bridge at Salem, Oregon

Timber Floor With Asphalt Wearing Surface—Pony Truss Span Supported by Cantilever—Arched Struts Used

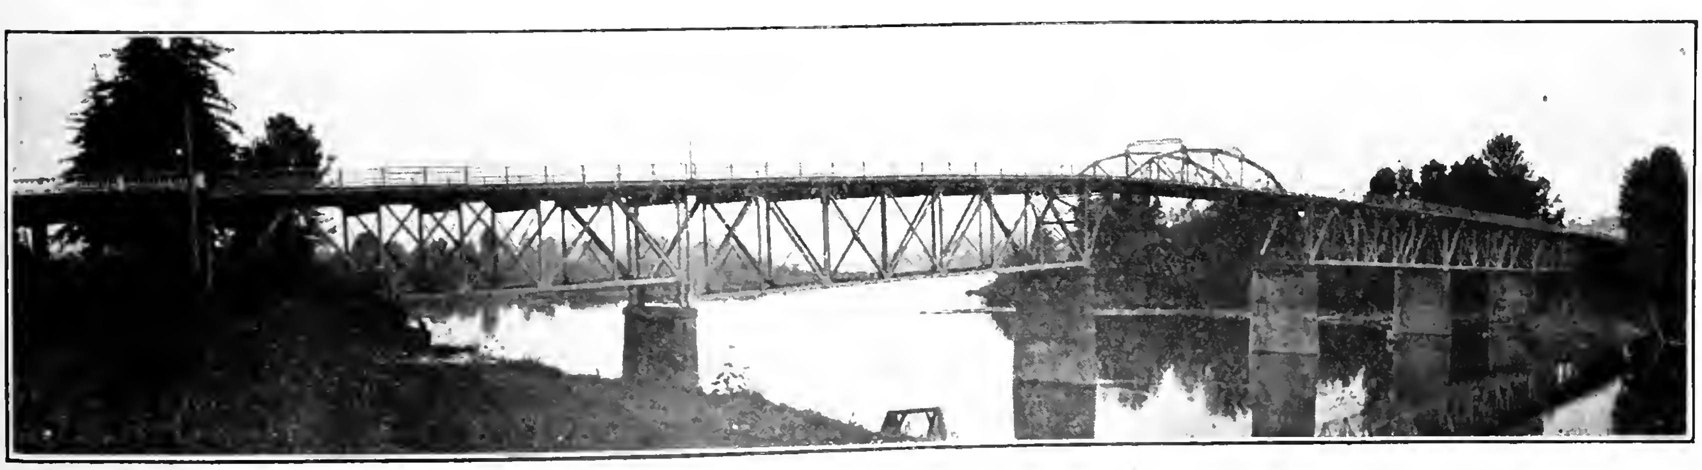
By Lewis W. Metzger
Designing Engineer, Oregon State Highway Commission

PROBABLY the longest highway bridge built recently is that over the Willamette River at Salem, Ore. It replaced two 360-ft. steel spans, erected in 1890, which were too light for the heavy modern traffic recently developed on this main highway through the Northwest. Several special features distinguish the design of this bridge, a composite structure with a reinforced-concrete approach on one side, a timber trestle approach on the other, and deck steel truss spans with a pony truss span 123 ft. long supported on cantilever arms to give the requisite clearance requirements. Curved latticed struts connect the trusses of the pony span. The floor throughout is built up solid of 3 x 7 fir members on edge, carried by steel stringers and by the top chords of the deck trusses, with a wearing surface of asphalt 3½ in. thick.

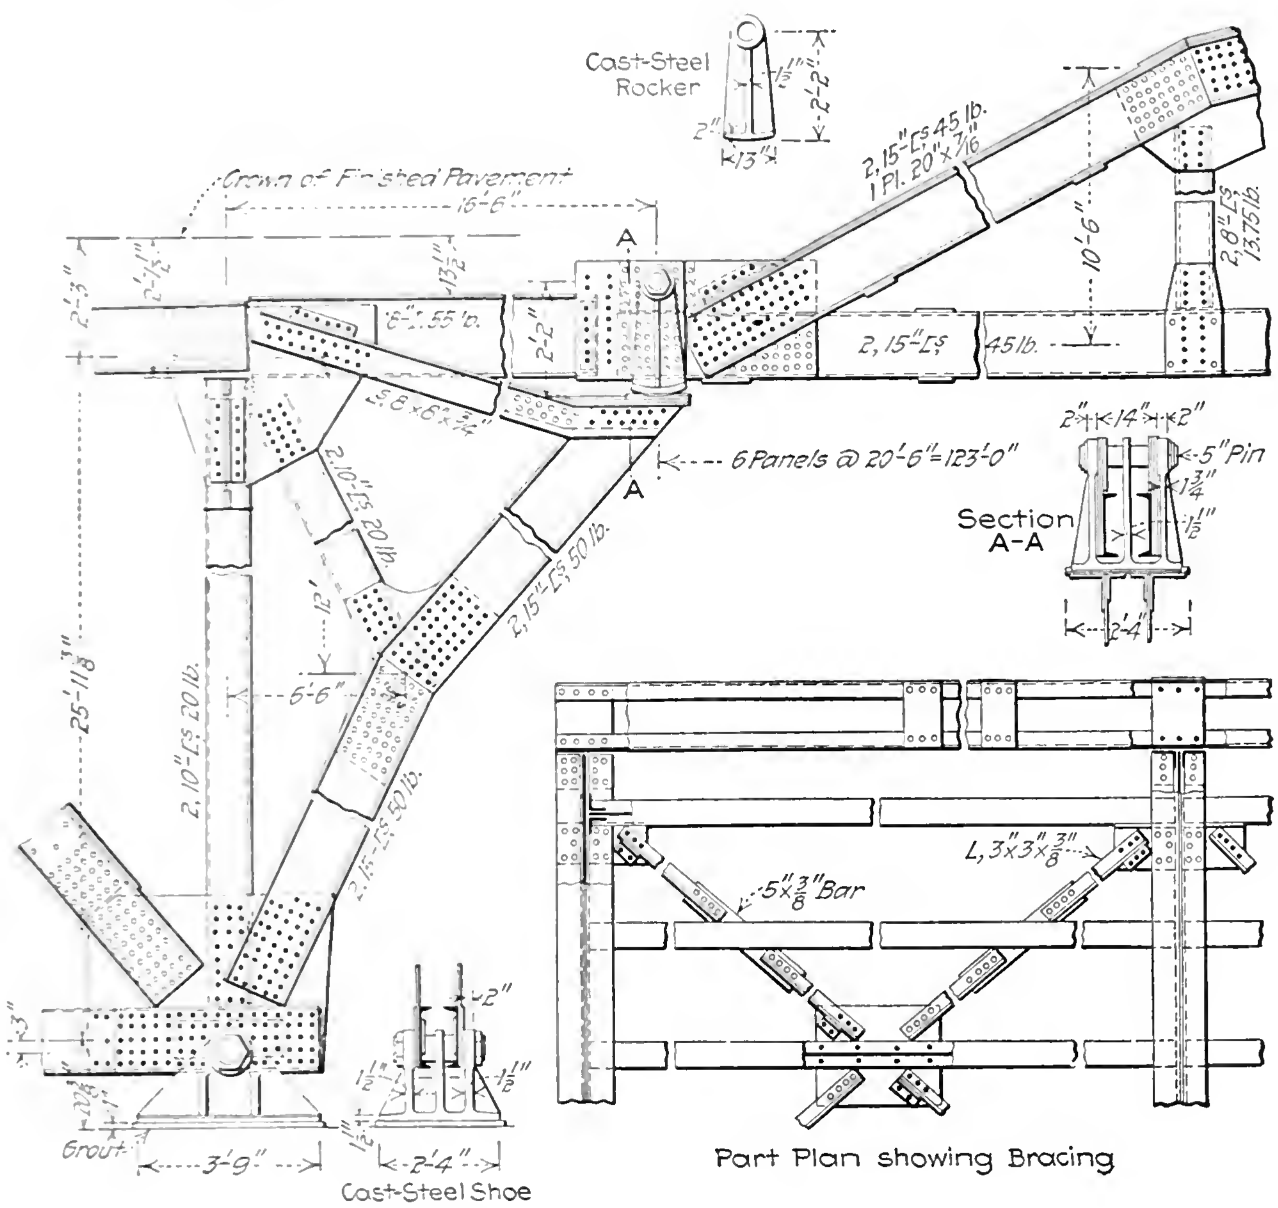
This design is the same as that described in *Engineering News-Record* of Nov. 8, 1917, p. 876, and was originally outlined by Joseph Weare, assistant state engineer. It consists of a pile trestle approach 780 ft. long on the Polk County side, four steel spans of the same length (152 ft. 3 in.) a single pony truss span 123 ft. long carried on cantilever supports from the adjacent spans, one shorter steel span (111 ft. long) and a reinforced-concrete approach 352 ft. long on the Marion County side. As the Willamette River is navigable at this point, United States engineers required a minimum horizontal clearance of 120 ft. and a vertical clearance of 66 ft. By the pony truss and cantilever design a clear opening of 145 ft. was provided.

The west approach follows a modern design of timber pile trestle type. The fir piling was treated in an open vat with carbolineum at a temperature of about 220 degrees Fahrenheit.

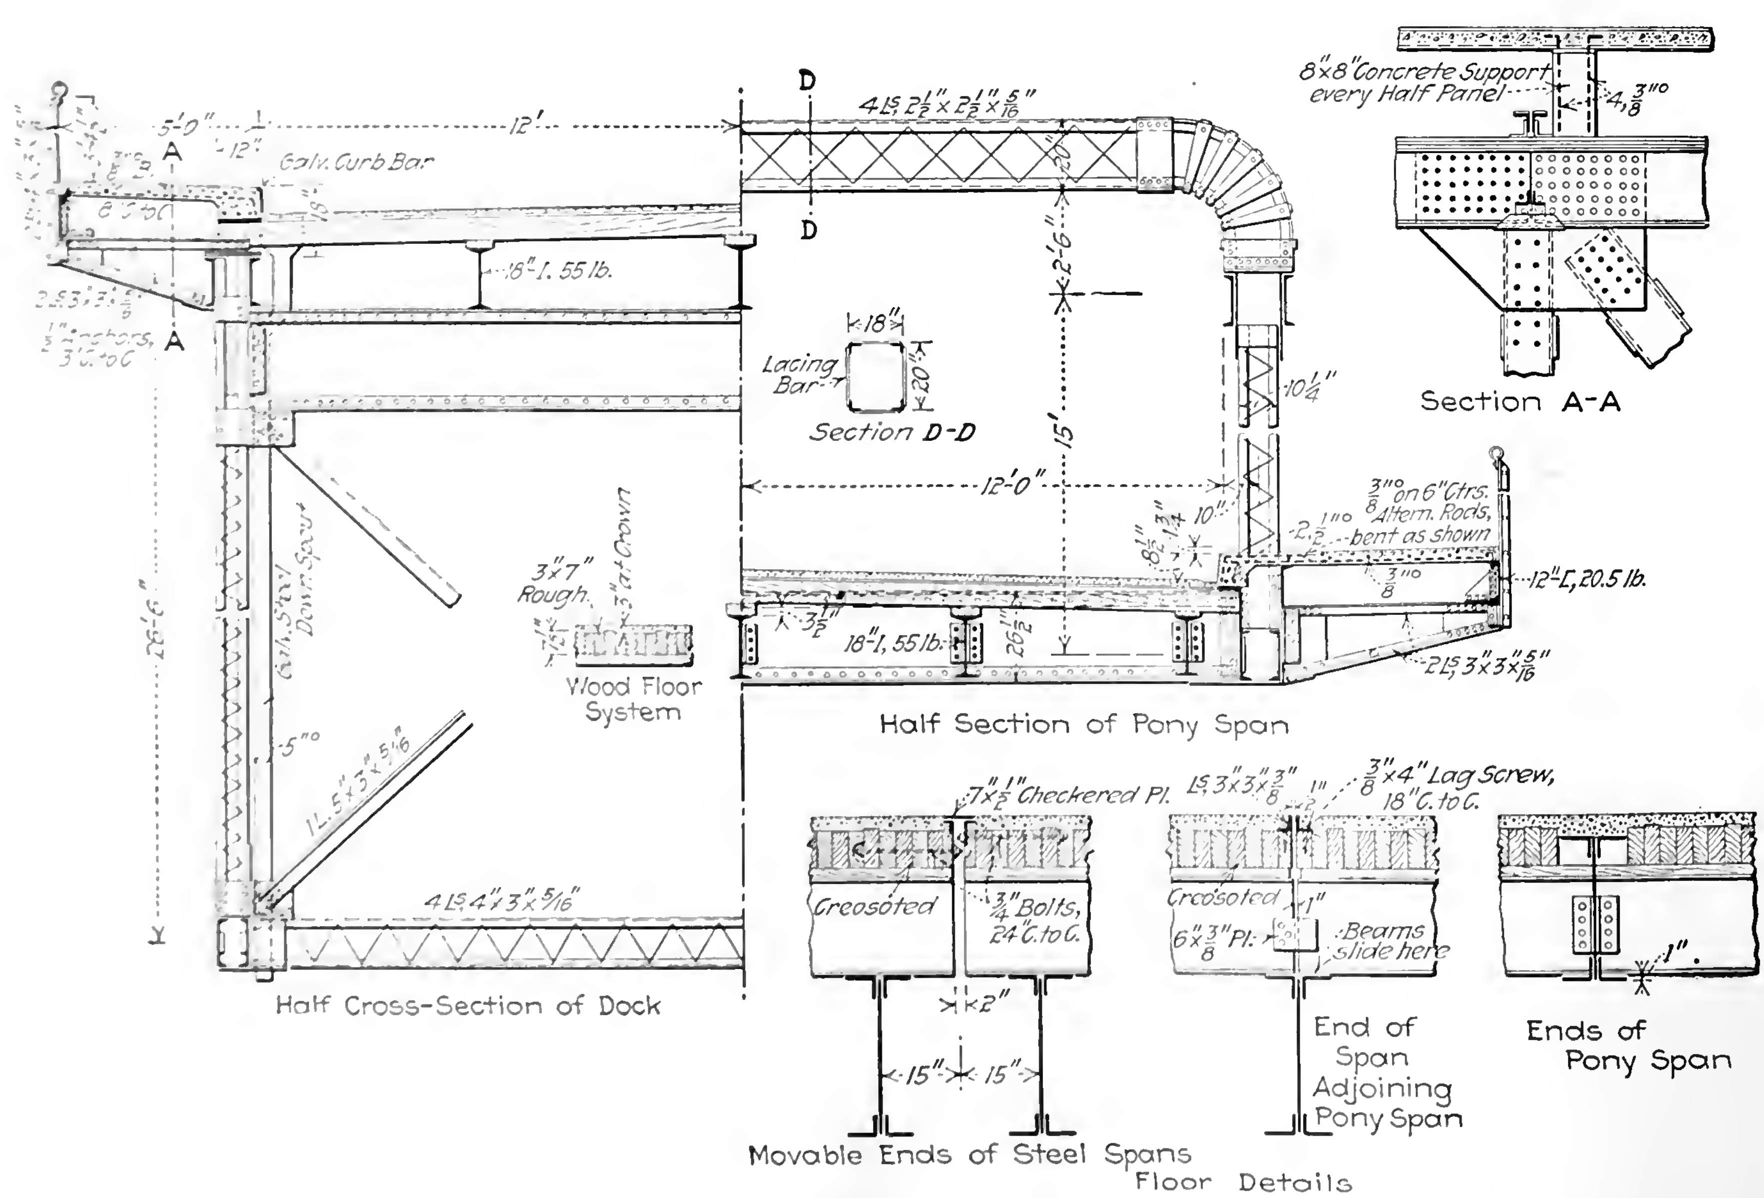
Lumber being comparatively cheap, the entire roadway deck of the bridge and wooden approach is com-



WILLAMETTE RIVER BRIDGE AT SALEM HAS PONY TRUSS SPAN SUPPORTED BY CANTILEVERS



posed of 3 x 7 in. x 26 ft. fir laid on edge, spiked together, and thus projecting 1 ft. on either side of the 24-ft. roadway. An asphaltic wearing surface 3½ in. thick effectively waterproofs the wood, and the small interstices between the pieces will allow sufficient circulation of air to preclude any possibility of attack by dry rot. The ends of the floor members were painted with hot carbolineum, as were also the wooden members contiguous to openings in the floor caused by expansion joints between the spans. The steel span adjacent to the east approach is not so deep as the adjoining one, and the difference in height is made up by means of a rocker which, of course, also serves the purpose of movable shoes. The channel span of the pony-truss type rests on cast-steel rockers on one end, each of which are carried by a shelf on the cantilever panel, projecting from the adjacent steel deck truss



UPPER—DETAILS AT EXPANSION END OF PONY SPAN. LOWER—TYPICAL CROSS-SECTIONS OF STEEL SPANS—FLOOR DETAILS AT EXPANSION JOINTS

span. The details of the movable end of this span are shown in one of the accompanying drawings. The other end of the span was pin-connected to a built-up shoe.

For the sake of economy it was decided to design the upper chords of the deck spans to serve as outside floor stringers, thus taking bending as well as direct compression. Wooden sleepers were bolted at intervals to the top chords, to facilitate the attaching of the wooden flooring. The typical cross-sections shown in one of the accompanying drawings indicate the nature of the details connecting the floor system with the steel trusses of both the deck and pony types.

The two 5-ft. concrete sidewalks are carried on brackets beyond the trusses, the curbs serving as reinforced-concrete beams. Small concrete struts extend up from the top of the top chords at the panel and mid-panel points. Between the bottom of the curb and the top of the wooden floor is a $\frac{3}{4}$-in. cushion of "Sarco." Owing to the grade of the bridge, it was necessary to precast this in sheets the width of the curb. When the material hardened it was rolled up in convenient lengths and placed.

It will be possible to renew the wooden floor with comparatively little difficulty, although it is believed that the wooden floor base, protected as it is, should last at least 50 years.

The final coat of battleship gray paint applied to the steel work has evoked favorable comment, being an innovation and a change from the black commonly used.

The cost of the crossing complete was about $250,000. The engineering cost was remarkably low. Including the surveys, borings, inspection of cement and steel fabrication, the resident engineer's salary, the cost of design, blueprints and supplies, and stenographic work, it amounted to $4600, or about 1.8% of the total cost.

The bridge was built by the Coast Bridge Co. and Robert Wakefield of Portland, Ore.; Charles McDonald was superintendent. The engineering work was done by the Oregon State Highway Commission. Herbert Nunn is state highway engineer. The writer was designing engineer.

Conserving City Water-Supplies in Southeastern Kansas

Recent Dry Seasons Resulted in Draining Natural Pools and, for More Permanent Results, in Formation of Reservoirs

By F. M. Veatch, Engineer, State Board of Health AND Professor F. N. Raymond, University of Kansas

THE severe drought in southeastern Kansas during the past two seasons has caused the working out of a fairly definite plan for conserving the water-supplies of the towns in that district. The city officials and the consulting engineers who have had most to do with these water-works plants, together with the state engineering departments, have been working not only to relieve present shortages, but also to safeguard the future and at the same time help toward a better use of the water resources of the whole district. These notes will describe the measures taken to increase and utilize stream storage.

Southeastern Kansas is not especially dry as compared with other parts of the prairie states, its mean annual rainfall, as calculated by the United States Weather Bureau, being above 35 in. The population is fairly numerous, however, and the people are largely engaged in mining and in oil and gas producing and attendant industries. There are some 50 towns of from 1000 to 20,000 population. Most of these have water-works systems that in ordinary times are very satisfactory. But these systems have usually been built in the first place mainly for fire protection, and the demands of communities growing both in population and the varied uses to which water is put have made the supplies more and more inadequate.

The recent drought was the severest on record. In the 20 months from January, 1917, to August, 1918, the rainfall was a little more than 60% of what is normally to be expected in these months. The water-supply ran low in the summer of 1917, but no great suffering was caused; the situation improved during the winter, but by June, 1918, many of the streams quit running, and the approach of the annual dry season caused much anxiety. In July service had to be restricted to domestic use in some towns, in order to prevent actual suffering. Railway supplies at city plants had to be cut off, and the shipping of cattle out of the country began. The trouble increased steadily until the latter part of August, when the rains began.

The surface water-supply for this district comes from the catchment areas of the Marais des Cygnes, Neosho, and Verdigris Rivers and some minor streams. The run-off varies from 0 to 13, and averages 0.4 to 0.5 sec.-ft. per square mile. The engineering problem, practically, is to provide storage reservoirs for water enough to last through a possible two years of drought.

Plenty of water is always to be found in the pools of the rock-bottomed Neosho for the small towns along the lower part of that stream. In other places, however, as along the Verdigris and the Marmaton, where the stream beds are soft, alluvial material, the natural pools cannot be depended upon. Generally, too, the flat country and the shallow channels of the streams do not afford good sites for large reservoirs.

The means for combatting the drought have heretofore depended almost altogether upon the conditions at each place at the time of shortage. At Cherryvale, for example, where the water is taken from the Verdigris River, ditches were cut from pool to pool in the river bed, and the contents of the pools all drained down to the reservoir at the city plant. But these ditches destroyed the storage value of the pools for the future. At Independence and Coffeyville, the largest towns in the district, similar ditching was done with similar results, also at other places.

In case pumps or siphons are used to convey water from pool to pool, the cost of obtaining and operating the extra equipment is often excessive—in fact, in some cases the cost of the work for a single dry spell has wiped out the profits of the plant for a year or more.

The logical development of the plan has been, therefore, to build dams at the points where the rock out-

croppings forming the pools occur. Such dams have valves so located that the water stored in the pools above them may be made available at will. Usually, a series of small dams is better than one large dam, for the small dams cause less trouble in case of flood.

The following cities have built or are building dams on this plan: Fort Scott, Neodesha, Eureka, Cherryvale, Independence, Coffeyville, Lyndon, Ottawa, Garnett and Cedarvale. The Verdigris (including its tributary, the Fall River) will be almost a continuous series of these storage reservoirs for many miles.

From the studies necessary in these cases, data are being gathered to supplement the general survey of surface-water resources in the district.

Balanced Rations and Good Cooks Cut Cost of Camp Messes

Investigation of Spruce Production Board Engineers Show 30 Per Cent. of Avoidable Food Wastes—Simple Meals Satisfy Workmen

BALANCED rations and good cooks will reduce food wastage in construction camps. This conclusion is arrived at by an analysis of mess practice in the lumbering industry, made by Capt. Thorfinn Tharaldsen, Spruce Production Board, Bureau of Aircraft Production, United States Army. Four principal kinds of waste exist: In buying, in storage, at table and at plate. Unbalanced rations, extravagant menus, improper storage and poor accounting are the causes of these wastes. They amount in the lumbering industry of the Northwest to from 20% to 30% of the total of foodstuffs purchased.

TABLE WASTES LARGEST ITEM OF FOOD WASTES

Too great a variety and too large quantities of food are prepared for each meal. Using the mess as an indirect method of attracting labor is often the reason for this extravagance. The remedy is the adoption of a standard ration list and a simple menu. A suggested ration list is given in the accompanying table. No more than one meat and one dessert should be served at any one meal. Further specification of menus is impracticable, since proficiency of the cooks, tastes of the men, accessibility to markets, season, market conditions, etc., determine the bills of fare at different times and places. Adoption of a system of monthly or bimonthly reports will aid in regulating the rations. A proper report form will show at a glance whether or not too much food is being used, which kinds are being used to excess, and whether the ration is well balanced.

Single meat and dessert menus are the solution of the problem of table waste. Meat and vegetables should be prepared only in such quantities as will probably be consumed at one meal. Meats, when placed on platters for serving, if cut into smaller pieces will permit the man to take as many portions as he may wish, but will not encourage him to take more than he can eat. Waste of leftover food can be reduced by skillful cooking which permits reservice in appetizing forms, as mentioned later.

Plate waste is due to men placing more food on their

SUGGESTED DAILY RATION LIST FOR CONSTRUCTION CAMP MESSES

	Pounds per Man per Day	Pounds per Man per 90 Meals
Meats, fish	1.25	37.50

plates than they can possibly eat. This is generally due to one of four causes: Too large portions placed on the serving platters; natural hoggishness of men with keen appetites; food sabotage, and unpalatability. The greatest waste is due to the first cause.

Plate waste can be largely eliminated by serving smaller portions and repeating the servings as the men ask for more. Instead of shortening the meals by "no talking" rules, encourage the men to lengthen the meal time. A personal appeal to the men not to waste food is effective if reduction of waste is accompanied by an immediate and corresponding reduction in the price of board. Food sabotage can be corrected only by punishment; observation shows very little malicious and intentional destruction of food in camp messes. A fourth remedy is to insist upon palatable food; this is a matter of getting good cooking, as is discussed later.

STORAGE AND BUYING WASTES EASILY CORRECTED

Buying foodstuffs is often put into the hands of someone who has little skill in balancing rations and in forecasting conditions. Often food is bought ahead for a gang of 50 men, when in the following month the gang may be reduced to 35 men; or a surplus of one kind of food is bought and not enough of another kind. Divided authority to purchase is another fault causing duplication of purchases, one by the camp cook and another by someone at headquarters. The remedy is to centralize buying authority and to educate the buyers in scientific catering.

Waste in storage is due chiefly to lack of cold-storage facilities. Some form of cold-storage apparatus in every camp of 50 or more men is a profitable investment. Another cause of storage waste is inadequate protection from destruction by rats, mice and other vermin.

A good, practical camp cook is the most valuable man in the camp, and his services should be properly recognized. Such a cook can save many times his wages in foodstuffs, and he is also a very important factor in the labor situation at his camp. It is a universal rule that men well fed will endure great hardships without grumbling. An incompetent cook will invariably mean

a full garbage bucket. He will waste many times his wages in food destroyed. Even the best quality of foodstuffs loses its value if improperly prepared by an incompetent cook. Such cooks are directly responsible for no small part of the wastage in the camp mess.

A good camp cook is cheap at almost any price, and an incompetent one is expensive, no matter how small his wage. A camp cook works long hours. From 4:30 a.m. to 8:30 p.m., seven days in the week, is a fair average. When his legs give out, he is accused of having "gone stale on the job," and his services are dispensed with "for the good of the service." It would seem wise to arrange to give each cook a short vacation, on full pay, at stated intervals.

Meat and potatoes should be served in different styles and varied in kind from day to day. Men have an inborn antipathy for "hash." Leftover meats should be re-served in form of stews, "mulligan," meat pie, etc., preferably with the addition of suitable quantities of fresh meats. Leftover meats and vegetables should be re-served in some form within 24 hours. Special care must be taken to see that no tainted meats or soured vegetables are used as an ingredient in any stew, meat pie, etc. No foodstuffs whose quality is questionable should be served under any circumstances. The meats should be properly washed and trimmed before they are prepared.

Frequent changes make all food more appetizing, and special attention must be given to the rotation of the different foods of the same kind. For instance, potatoes served mashed at every meal become tiresome, while if served baked, fried, boiled and mashed in rotation they are very palatable. A steady beef diet loses its attraction in a short time, while if the meat diet is made up of beef, pork, mutton, fish, etc., in rotation, with beef preponderating, this will not occur.

The success or failure of any meal depends largely on the manner in which it is served. Careless, sloppy service will ruin the best prepared meals. Everything should be neat and clean; meals must be served promptly, and dirty dishes removed quickly and quietly. Sloppy service will upset a camp as quickly as it will a hotel. Complaints should be made privately to the person in charge and not to cooks or waiters, and prompt investigation and adjustment of the matter should follow.

What Part the Engineer Played in Government Housing

Report of Chief Engineer of the United States Housing Corporation Outlines Work of His Division

ENGINEERS in general are not too conversant with the part they can play in housing developments. For their information there is printed below a large part of the report of John W. Alvord, the Chicago consulting engineer who was chief engineer of the United States Housing Corporation. Mr. Alvord's report outlines the work of his division in the construction of the many housing projects undertaken by the Department of Labor under a $60,000,000 appropriation. The signing of the armistice cut off the completion of most of the projects of this bureau, but the engineering work made up a large portion of the preliminary operations.

Mr. Alvord's report follows:

The Engineering Division of the United States Housing Corporation was early formed because the proposed Government housing is principally conducted in cities, or closely adjacent thereto, and it became necessary to obtain the aid and advice of engineers familiar with municipal and public utility work to plan and supervise these improvements and make the necessary arrangements with the municipalities in which they were operating, and also to contract with utility companies whose service was needed.

Extent of Housing Undertaken

The work has included the planning and negotiation for the extension of municipal improvements, such as drainage, sewerage, water-supply, electric light, fire-alarm systems, fire protection, gas, sidewalks, gutters, street paving, street lighting, sewage-treatment plants, pumping stations and other municipal improvements.

In connection with the housing bureau program, 60 or more developments projected in various parts of the country have reached the stage of engineering planning. These range all the way from 25 to 3000 families per development, and there have been necessarily planned for this work in the aggregate the following municipal improvements:

180 miles of sewer, costing about $2,852,700.
160 miles of water pipe, costing about $2,672,600.
11 independent pumping stations for water-supply.
83 miles of gas lines, costing about $637,700.
145 miles of eletcric transmission systems, at $775,000.
135 miles of street paving, curbs and gutters, costing $3,060,300.
260 miles of sidewalks, $1,234,300.
2877 street lights.
6 sewage-pumping plants.
13 sewage-treatment plants.

The total cost of all contemplated municipal area utility improvements will approximate $13,060,000.

The necessity for working in coöperation with the municipality in which the development is situated has necessitated negotiation with over 60 mayors, city councils and city engineers as to the inter-relations of the bureau with the municipality. In each case it has been urged upon the city that it is their privilege and duty to assist the bureau, as far as possible, by doing for the Government at least what would usually be done for a private individual making a similar investment. In many cases more than this amount of aid has been sought, and in some cases generously extended.

In some cases the inter-relations with municipalities have necessitated loans; in other cases complex special assessment relations; often aid to the city in urging permission for the issue of securities by the Capital Issues Committee; and, nearly always, obtaining priority orders for material and negotiating regulations made by the War Industries Board for emergency exclusion of expensive materials, difficult to obtain in the view of other war demands, and the adaptation instead of local materials.

For this purpose the Engineering Division has, of necessity, been largely composed of municipal engineers, especially skilled in municipal work, assessment law, city regulations, precedents and practices. The Engineering Division, through its negotiations, has obtained aid

from municipalities to the extent of \$3,103,000 or 24% of the total cost of the total utility and municipal work contemplated.

The Engineering Division has further been entrusted with the negotiations with private utility companies for the necessary service for the bureau developments of gas, electric lights, water-supply, and, in some few cases, of heating facilities and telephone service as well.

In all some 250 negotiations have been conducted, a large portion of which have been brought to a successful termination. In many instances it has been necessary to come to the assistance of utility companies which were financially embarrassed, yet whose continued service was essential to the development and the Government in adjacent war industry. In these cases, a financial adviser, skilled in utility securities and banking, has reported carefully upon the financial ability of the company, and its ability to furnish necessary collateral. Where good banking loans could be had, the utility has been financed through approval of the Capital Issues Committee. In cases where good banking loans are not available, utilities have at times been financed by the bureau direct, making the loan upon such collateral as was available.

In every case, it has been urged upon utility companies that they ought to accord the bureau the same service, if not more service, than they would accord a private investment under similar circumstances. The necessity of the situation has required contract relations or negotiations with 48 gas companies, 67 electric companies, and 40 water companies, or about 150 utility companies in all.

The Engineering Division, through its negotiations and efforts, has obtained aid and financial investment from utility companies for United States housing to the extent of \$1,600,000, or 12.3% of the total cost of utility investment. The total amount raised by suggestion and negotiation of the Engineering Division from municipalities and utility companies for United States housing requirements has been \$4,702,700, or 36.2% of the total requirements of \$13,040,134, estimated utility expenditure. Of the \$4,702,700 raised from municipalities and utility companies, about one-half, or \$2,216,900, has been financed by the municipalities and utility companies, and the remainder loaned them by the bureau, to be repaid to the Government in the near future.

Preliminary Investigations

The Engineering Division has been employed in making preliminary investigations for the bureau in connection with the selection of local sites for housing developments. This matter, almost always difficult to determine, has been handled by a committee consisting of an engineer, an architect, a realtor and town planner, and in each case all sites offered or suggested have been carefully canvassed, their development cost estimated, and the selection made on the basis of actual desirability regardless of all private interests.

The Engineering Division at the central bureau consists of a chief engineer, an engineering secretary to the chief, a chief assistant, 10 district engineers (each of whom has conducted the individual details of a group of projects), two utility engineers, one road engineer (lent by the Bureau of Roads and Rural Engineering), one fire-protection engineer (lent by the National Board of Fire Underwriters), two electrical engineers, an attorney on contract relations, and an engineer in charge of engineering contracts, bills and accounts, and four stenographers—about 25 in all.

Organization of Engineering Division

The duties of the central staff have been:

1. To prepare a manual of standard directions for local project engineering designers, and
2. Standard instructions, drawings and specifications and directions.
3. To act as adviser to other divisions on engineering questions.
4. To report on all unusual or difficult engineering problems, such as constantly arise.
5. To select, appoint and contract with all local project engineers and their assistants.
6. To guide and direct the local project engineers.
7. To revise the budget allowance in accordance with the policy of the bureau.
8. To initiate and conduct all contract relations with city and utility companies.
9. To approve all detailed plans, estimates and specifications of such local project engineers and control their operations.
10. To check the bills of material.
11. To advise the town-planning and construction divisions on all engineering questions.

In the field some 60 local project engineers have been appointed who have been either persons or firms having locally efficient office, organization, acquaintance, equipment and financial ability in addition to specialized training in municipal problems, and who could do rush work on short notice in the preparation of plans, conducting negotiations and the supervision and construction of local development projects. Contracts with the local project engineers have been on a uniform contract form prepared by the Engineering Division, and based on a scale of fees less than ordinarily earned but thought to be sufficient, in which all contracting engineers have been uniformly treated alike. The fees and overhead expenses have been on a sliding scale, reducing in cost per house with the increase of the development, and prepared on the basis that the municipal improvements would vary approximately with the number of houses in each development. The average of fees and overhead allowance has been but 1% on the cost of utilities involved, amounting to about \$2500 on a 200-house development, and increasing to about \$4500 on a 1000-house development, in addition to which the project engineer received actual cost for his assistants, the traveling expenses and such obvious expense as could be readily checked by the fiscal division.

Oil Production Gains Three Per Cent Over 1917

A gain of 3% over the record production of petroleum in 1917 is indicated in the preliminary estimate for 1918. An estimate of nearly 350,000,000 barrels, as against the record for 1917 of over 335,000,000 barrels, is made. The reserve of crude oil held by all producers and pipe-line companies in the United States at the end of 1918 is estimated at 123,000,000 barrels, as compared with 150,000,000 barrels at the end of 1917.

ENGINEERING LITERATURE

A REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Flow of Water in Open Channels

REVIEWED BY ROBERT E. HORTON
Consulting Hydraulic Engineer, Albany, N. Y.

CALCULATION OF FLOW IN OPEN CHANNELS—By Ivan E. Houk, Assoc. M. Am. Soc. C. E. Technical Reports, Part IV. The Miami Conservancy District. Dayton, Ohio: The District. Paper; 6 x 9 in.; pp. 283; illustrated. 75c.

More perhaps than any other branch of engineering, hydraulic science has received numerous contributions during recent years, in the form of elaborate technical reports. Dating back to the monumental United States Deep Waterways Report of 1898, and running through the series of reports on the New York water-supply, the New York Barge Canal, and others, later, resembling these prototypes, there has probably been none which contained so much in the way of definite contributions to hydraulic theory and practice as the series issued by the Miami Conservancy District, of which the work under review is one.

Apparently, the title might better have been "Formulas for Flow in Open Channels," as the book is devoted almost entirely to a discussion of numerous formulas for flow in open channels and the presentation of experimental data to test the accuracy of these formulas. There is a great deal of technic to the calculation of flow in open channels that is quite apart from the formulas used and is not gone into in this book, except as it is involved incidentally in the computation of experiments here recorded.

By way of clearing the ground of minor criticisms, it might be noted that formulas in which the exponents of the hydraulic radius r or the slope s have values other than one-half as in the Chezy formula are here referred to as "exponential formulas." The term "exponential formula" has a definite meaning in mathematics, and refers to an expression where the exponent is a variable. That is not true with regard to these formulas. Furthermore, the Chezy formula is as much an exponential formula in the sense of the term used in this book as any of the others. It is true that this loose terminology has been used before. What is meant is that the exponent of r or s or both is not one-half as in the Chezy formula. The various formulas referred to are all special cases of a general nth-power formula.

The formula devised by the Swiss engineers, Ganguillet and Kutter, is often referred to here, as it is elsewhere, as Kutter's formula. Failure to give Ganguillet equal participation in the credit appears unjustified even on the plea of abbreviation, but the practice is probably too well established to be easily changed.

The book contains calculations of maximum discharges in the flood of 1913 in the Miami Valley, using Ganguillet and Kutter's formula with coefficients of roughness checked by special experiments on reaches of the same or similar streams. This part of the book affords convincing proof that reasonably reliable and satisfactory determinations of flood discharge can be obtained in this way, and the manner in which the work was done and is described in the book is worthy of commendation. Incidentally, a method of calculating discharge from the drop in the water level during floods in passing through contracted bridge openings is described. Such methods are often needed, and the one presented here will probably find useful applications.

To most hydraulic engineers Chapter IV, containing the results of some 84 experiments for the determination of the coefficient of roughness in natural river channels, will be of great interest and value. Details of the experiments are given in full, with descriptions of the character of each river reach on which experiments were performed. These descriptions are accompanied, in several instances, by photographs which convey some idea of the roughness and channel conditions involved in the experiments. On the theory that these photographs will be useful to engineers generally who desire to apply the results of these experiments, it would seem that a much larger number of such photographs would have further increased the value of the data presented.

Abstracts and translations of original papers are included in the book, showing clearly the development of various slope formulas and the antecedents of such formulas, especially those of Ganguillet and Kutter, and Bazin. Many formulas less generally known are discussed, including the German and Austrian formulas of Siedek, Hessle, Christen, Hermanek, Biel, Matakiewitz and Lindboe. The author concludes—and without doubt correctly—that not one of these formulas is of much practical value. They are mostly based on considerations of an ideal channel, and like much German literature on kindred subjects in hydraulics and hydrology, they are stronger in the speculative than in the practical aspects of the subject. However, they are interesting if only as museum specimens, and may afford useful suggestions. Other recent formulas, including those of Schmeer and Barnes, are discussed but the general conclusion is reached that "although the Kutter formula is not ideal it is the best equation available at the present time."

Confirming its general use and utility, a brief list is given of some recent important hydraulic works on which the Ganguillet and Kuttler formula was used. In this list should have been included the New York State Barge Canal, probably the most important example of all in this respect, in that it involved over 400 miles of large natural and artificial channels, the hydraulic features of which were determined by the Ganguillet and Kutter formula. The substantial accuracy of these determinations has been verified by subsequent experience.

Criticisms frequently made of the Ganguillet and Kutter formula are cited. These are of two classes: (1) Criticisms, often sweeping, which are in effect only a confession of ignorance on the part of the critics; (2) specific criticism of the inclusion of a slope factor

in the formula, or of its accuracy when applied to very flat slopes. The slope factor was included in the original formula to adapt it to Humphreys and Abbott's gagings of the Mississippi River, and to answer this question recent gagings of the lower Mississippi are used. The evidence presented is not so convincing, one way or the other, that the reader may not interpret it differently from the author.

There is some discussion of Manning's formulas. The conclusion is reached that in most ordinary cases they give results practically identical with the Ganguillet and Kutter formula, with the same coefficient of roughness.

For very flat slopes and large channels, the author prefers the Ganguillet and Kutter formula with the slope correction factor (omitted from the Manning formulas). For such conditions the Manning and the Ganguillet and Kutter formulas do not agree with the same value of n and a question arises as to which is nearer the truth. The author states (p. 243): "The average error of the results calculated by the Manning formula for the gagings of Humphrey and Abbott was 19.8 per cent., while the average of those calculated by Kutter's formula was only 4 per cent." For very flat slopes the Ganguillet and Kutter formula gives the higher velocities. If, therefore, the reported velocities in the Humphreys and Abbott experiments are, say 8 per cent. too high, as elsewhere concluded, the showing would be changed to an error from the truth probably about equal for the two formulas.

King's "Handbook of Hydraulics" appeared about the time when Houk's book went to press, and is not cited by Houk. King's book contains a much more elaborate and thorough discussion of the relation of the Manning and the Ganguillet and Kutter formulas, and the conclusions of Houk on this subject should be read in conjunction with King's discussion.

It will probably appear to many that, except perhaps for very flat slopes on large streams, the Manning formula has the great advantage of simplicity, and yet one trained in the selection of values of n for one formula can in general apply these directly to the other, with assurance that in most cases the results will be nearly identical.

It seems also proper to add to the author's discussion that for very flat slopes, where the velocity in an appreciable portion of the cross-section is below the critical velocity, further exploration is needed. Here there is good physical reason for a slope correction, or else the use of a formula involving terms both for v and v^2, as in earlier formulas of Prony and Eytewein. The general comparison of slope formulas in Houk's book supplements and brings down to date a similar comparison contained in Humphreys and Abbott's classical monograph, in the added light of later experience. The book is a welcome and timely addition to the literature of hydraulics.

Shutting Water Out of Cased Wells

METHODS OF SHUTTING OFF WATER IN OIL AND GAS WELLS—By F. B. Tough. Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 122; illustrated. 30c. from Superintendent of Documents.

Although written for oil and gas men, this excellent monograph contains much information equally useful for water-supply engineers and contractors. In oil- and gas-well practice it may be necessary to shut out water from either the bottom or the sides of the well. In water wells, the shutting out is usually from the sides, and reliance is often placed upon the casing—which may sooner or later prove inefficient—or it may be considered cheaper to use a thin casing, backed with cement grout. Most of this bulletin is devoted to the subject of stopping water inflow by cement, but attention is also given to the use of hydraulic lime and mud fluid. Equipment for cementing and also for mudding is described. There is also a section on calculating the thickness of casing needed for various depths.

A Current Compendium on Concrete

AMERICAN CONCRETE INSTITUTE: Proceedings of the Fourteenth Annual Convention, Atlantic City, N. J., June 27-29, 1918. Chicago, Ill.: The Institute. Cloth, 6 x 9 in.; pp. 581; illustrated.

Annual reports of societies, containing the papers presented at their meetings, are, as a rule, merely listed in this section, but the great specialization of the papers presented before the American Concrete Institute makes it worth while to give more than ordinary notice to the volume of "Proceedings" recently issued. While most of the papers are up to the usual average, there are three special features of the 1918 "Proceedings" to which concrete engineers should give great attention. The first is the paper by Prof. D. A. Abrams of the Structural Materials Laboratory, Chicago, entitled "Effect of Time of Mixing on the Strength and Wear of Concrete." The second is the report of the Committee on Concrete Roads and Pavements; and the third is the group of papers on concrete ships.

Professor Abrams' paper takes 70 pages of the "Proceedings." It is an exposition of an elaborate series of tests on various kinds of concrete, and embraces very much more than its title would indicate. For instance, the amount of water, the effect of consistency, the relative value of materials, grading, etc., all are discussed by the author. As it stands, it is the most complete résumé of concrete tests since that issued some years ago by the United States Bureau of Standards. The Committee on Roads and Pavements makes its report almost entirely of a 60-p. document entitled "Recommended Practice for Concrete Roads," by far the most recent and advanced statement of concrete-road technic that has yet been published. It contains drawings and photographs descriptive of recent concrete-road practice, as well as analyses of contractors' organizations and estimates of costs. The concrete-ship papers are noteworthy, and, with the present interest in that art, should receive considerable attention.

An Engineer in Action at the Front

FIGHTING THE BOCHE UNDERGROUND—By H. D. Trounce, Formerly of the Royal British Engineers; now Captain of Engineers, U. S. A. New York: Charles Scribner's Sons. Cloth; 5 x 8 in.; pp. 231; illustrated. $1.50.

Born in England and having spent most of his life there, the author went to Canada on coming of age, then attended the Colorado School of Mines, and in 1910 settled in California, where he practiced as a mining engineer and became an American citizen. In the latter part of 1915 he went to England, obtained a lieutenancy in the Royal Engineers, and for 18 months was at the front, engaged mostly in sapping and mining

operations. In the middle of 1917 he returned to California, and in October was commissioned as captain in the Engineer Officers' Reserve Corps. Meanwhile, at the solicitation of friends, this book was written.

The volume is a straightforward account of the author's experiences, largely in explosive mine tunnel work, at Vimy Ridge, on the Aisne, at Arras and on the Hindenburg line. Concluding chapters deal interestingly and informingly with "The Psychology of Fear" and "Some Principles of Mining," the latter being illustrated with sketches and a folding map. The volume has both general and technical interest.

Useful Notes on Rural Roads

THE LOCATION, CONSTRUCTION AND MAINTENANCE OF ROADS—By John M. Goodell. Reprinted from "Good Roads Year Book" 1917. New York: D. Van Nostrand Co. Cloth; 6 x 9 in.; pp. 207; illustrated. $1.

Discussion of rural road problems without the confusion inherent in a combined work on both urban and rural highway improvements is a feature of this work. In its preparation Mr. Goodell had the coöperation of over 50 leading highway engineers of America.

Location, general design and plans are first treated. Following this the various types of road ordinarily used in rural districts are taken up, separately, and are discussed as to the approved practice for specifications, construction and maintenance. Interspersed with these are special chapters on cement, petroleum and residuums, asphalt, tar and tar products, with specifications for each.

Following these constructional and maintenance features are general chapters covering highway bonds, the tractive resistance of various types of roads, and tables showing the mileage and improved condition of roads throughout the United States. The book closes with a chapter setting forth the general arguments to be used in promoting good-roads sentiment.

An Engineer's Forecast

THE ENGINEERING PROFESSION FIFTY YEARS HENCE—By Dr. J. A. L. Waddell, D. Sc., D. E., LL. D., Consulting Engineer; Reprinted from *The Scientific Monthly*, Vol. VI, No. 6, June, 1918, and Vol. VII, Nos. 1 and 2, July and August, 1918. Kansas City, Mo.: The Author. Paper; 7 x 10 in.; pp. 54.

First delivered before various engineering schools and societies, this lecture consists of a "Prelude"—treating of present conditions "affecting the welfare of the engineering profession, the long-continued attempt to establish an American Academy of Engineers, and what can best be done to take advantage of existing possibilities for the advancement of engineering in the United States"—and a "Retrospect." The latter is "intended to indicate what is practicable of accomplishment for the profession in the next half century, although it must be confessed that occasionally there is inserted in lighter vein a suggestion which might properly be termed imaginative."

The author's object in putting the lecture in print is to give engineers in general some topics to consider that are essentially different in type from those which they encounter in their daily routine of work—in the hope that, ultimately, at least a few of the innovations suggested may be materialized. The "Retrospect," which occupies most of the space, is supposed to have been delivered in 1968, by J. A. L. Waddell, 2nd. In the flights of his imagination the author sees many if not most of the pet projects of himself and his more intimate friends brought to a happy conclusion—thanks largely to the academies of engineers, economics and law and the Society for the Promotion of Engineering Education.

Studies for Railway Projects in India

RULES FOR THE PREPARATION OF RAILWAY PROJECTS, 1918: With Notes by G. Richards, M. Inst. C. E., Chief Engineer with the Railway Board, India. Simla, India: Railway Board. Paper; 8 x 13 in.; pp. 55; illustrated by typical plan and profile.

Instructions as to estimates of traffic earnings and operating expenses are a prominent feature of this book of rules, which is a revision of earlier editions.

General instructions are given in regard to preliminary survey or proper location, made by compass traverse; also for location survey by instruments. The instructions for fieldwork are based on the use of the 100-ft. chain. Compensation for grade is specified for both easy and sharp curves, the prescribed rate being 0.04% per degree of curvature on the 5½-ft. gage, 0.03% for meter gage, 0.02% for 30-in. gage and 0.015% for 24-in. gage, all these various widths of gage being included in the railway system of India. Transition curves are required and are to be spirals based on the cubic parabola. Other rules relate to the prescribed proceedings and forms for plans, profiles, estimates and reports; specimens of these are given.

Notes on Stadia Surveying

TOPOGRAPHIC STADIA SURVEYING: A Manual with Reduction Tables and a New Type of Reduction Diagram—By C. E. Grunsky, Eng. D., Mem. Am. Soc. C. E. New York: D. Van Nostrand Co. Flexible Cloth; 5 x 7 in.; pp. 95; illustrated (with pocket containing stadia reduction diagram.) $2.

The author of this little handbook, a well-known consulting engineer of San Francisco, presents these notes on stadia surveying, and a useful stadia reduction diagram which he has prepared as a result of many years' practical experience in such work. He plunges into technical definitions without any preliminary introduction, and describes the Porro telescope and other special terms. The theoretical formulas and descriptions of a satisfactory type of stadia rod are clearly presented, and are followed by a concise description of stadia surveying methods, with practical suggestions. In the chapter on the latter subject, he lists six departures from ordinary methods, relating to (1) the type of rod; (2) the elimination from the notes of the height of the telescope above a station plug; (3) the liberal use of the magnetic needle; (4) the method of keeping field notes; (5) the use of approximation formulas, and (6) the use of convenient stadia reduction diagrams.

The correction tables included and the satisfactory samples of notes should be helpful, also the hints on plotting stadia notes. C. G. Anderson's tables for reduction of stadia, used by the United States Geological Survey, are reproduced, and a complete explanation of the author's special stadia diagram is given.

British Engineering Standards

The British Engineering Standards Association (28 Victoria St., London, S.W., England), announces that as soon as necessary arrangements can be made its 87

publications, with a few exceptions, will be issued in French, Italian, Spanish and Russian, and that both these and the corresponding English texts will be sold at 1s. apiece, plus postage—generally 2d. The association was founded in 1901, as the Engineering Standards Committee, by five British technical societies—the Institutions of (1) Civil (2) Mechanical and (3) Electrical Engineers and (4) Naval Architects and (5) the Iron and Steel Institute. Among the subjects covered by the specifications thus far published are: Rolled structural sections; rails; portland cement; steel for bridges and buildings; cast-iron pipe, separately for (1) water, gas and sewage, (2) hydraulic power, (3) soil pipe, (4) waste and ventilating pipe; salt-glazed sewer pipe; tar, pitches, bitumens and asphalts for road purchases. A new report, just at hand, deals with fine screw-threads.

Progress Report on Run-Off

Pending the completion of its investigations and report, the Boston Society of Civil Engineers' Committee on Run-off has published a progress report consisting of a glossary of run-off terms, and five papers. The latter are as follows: "The 0.2 and 0.8' Method in Power Canals," and "Precipitation, Evaporation and Run-Off," by Arthur T. Safford, chairman of the committee; "Use of the Current Meter in Stream Gagings;" "Effect of Ice on River Discharge" and "Methods to Use in Compilation of Data," by C. H. Pierce, secretary. These papers, with a prefatory note by Mr. Safford, fill 35 pages of the *Journal* of the Boston Society of Civil Engineers for November, 1918 (Tremont Temple, Boston; 50c.).

Spanish-English Specifications

To facilitate foreign trade, the United States Bureau of Foreign and Domestic Commerce and the United States Bureau of Standards are coöperating in translating for circulation abroad "standards for materials of various kinds, commercially acceptable and representing good American practice." Thus far four specifications of the American Society for Testing Materials have been translated into Spanish and printed in that language and in English, on facing pages. The latest of these (Nos. 3 and 4), translated by Antonio Lano, cover (No. 3) open-hearth steel girder and high-tee rails and (No. 4) low-carbon steel splice bars (5c. each, from Superintendent of Documents, Washington, D. C.). No. 1 covered portland cement and No. 2 dealt with carbon-steel rails.

PUBLICATIONS RECEIVED

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be obtained without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other persons indicated.]

BUILDINGS AND EQUIPMENT FOR SCHOOLS AND CLASSES IN TRADE AND INDUSTRIAL SUBJECTS: Trade and Industrial Series No. 4—Washington, D. C.: Federal Board for Vocational Education. Paper; 6 x 9 in.; pp. 72; illustrated.

BUREAU OF STANDARDS, ANNUAL REPORT OF THE DIRECTOR TO THE SECRETARY OF COMMERCE: June 30, 1918—Washington, D. C.: Bureau of Standards. Paper; 6 x 9 in.; pp. 206.

The number and variety of services rendered by the Bureau of Standards, as disclosed by this report, is far beyond what those not familiar with the work of the bureau would suppose. The pamphlet deserves wide circulation in order that the work of the bureau may be better known and a wider opportunity thus be given for utilizing its services.

COUNCIL OF NATIONAL DEFENSE: Second Annual Report, June 30, 1918—Washington, D. C.: The Council. Paper; 6 x 9 in.; pp. 275.

DIRECTOR OF THE BUREAU OF MINES: Annual Report to the Secretary of the Interior, June 30, 1918—Washington, D. C.: Bureau of Mines. Paper; 6 x 9 in.; pp. 118. 10c. from Superintendent of Documents.

FERRO-CONCRETE IN INDIA—By G. Richards, M. Inst. C. E., Chief Engineer with the Railway Board. Simla, India: The Author. Paper; 9 x 12 in.; pp. 85; illustrated.

The use of concrete is not confined to the United States and to Europe, as this document shows. For some time the Railway Board of India has been issuing technical papers through its chief engineer's office. A number of those relating to reinforced concrete have been gathered together and are now published under one cover. The pamphlet contains details of structures, paragraphs of specifications, results of tests, contract provisions, etc., all of which might be useful to American concrete engineers who wish to be fully informed on the progress of their art.

GRAPHICAL AND MECHANICAL COMPUTATION—By Joseph Lipka, Ph.D., Assistant Professor of Mathematics in the Massachusetts Institute of Technology. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 264; illustrated. $4.

HIGHWAY MAINTENANCE: Devoted Especially to Patrol Maintenance on the State Trunk Highway System—Compiled by J. T. Donaghey, Maintenance Engineer. Madison, Wis.: Highway Commission. Paper; 6 x 9 in.; pp. 69; illustrated.

Contains instructions for those in charge of highway maintenance, including patrolmen, maintenance foremen, and county highway commissioners. Sets forth the proper methods to be used in each kind of work, the best time of year for each kind of road, the best weather conditions for each kind of work, and the kind of machinery to use and how to use it.

INTERNATIONAL HEALTH BOARD: Fourth Annual Report, Jan. 1, 1917-Dec. 31, 1917—New York: The Rockefeller Foundation. Paper; 6 x 9 in.; pp. 147; illustrated.

INVESTMENTS IN LATIN AMERICA AND THE BRITISH WEST INDIES—By Frederic M. Halsey, Special Agent, Washington, D. C.: Bureau of Foreign and Domestic Commerce. Paper; 6 x 9 in.; pp. 544; illustrated. 50c. from Superintendent of Documents.

JOHNSON'S MATERIALS OF CONSTRUCTION: Rewritten by M. O. Withey, Associate Professor of Mechanics in the University of Wisconsin, and James Aston, Metallurgist with the A. M. Byers Co. of Pittsburgh. Edited by F. E. Turneaure, Dean of the College of Engineering of the University of Wisconsin. Fifth Edition. New York.: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6 x 9 in.; pp. 829; illustrated. $6.

OXWELDING AND CUTTING: Manual of Instruction—Newark, N. J.: Oxweld Acetylene Co. Paper; 5 x 8 in.; pp. 124; illustrated. 50c. Without Charge to Users of Oxweld Acetylene Apparatus.

REPORT OF THE COMMISSION APPOINTED TO DELIMIT THE BOUNDARY BETWEEN THE PROVINCES OF ALBERTA AND BRITISH COLUMBIA: Part I, 1913-16. Commissioners, R. W. Cautley, D.L.S., A.L.S., J. N. Wallace, D.L.S., A. O. Wheeler, B.C.L.S. Ottawa, Can.: Office of the Surveyor General. Cloth; 7 x 10 in.; pp. 189; illustrated. Atlas; 19 x 15 in. pp. 27

RETAINING WALLS: Based Entirely on the Theory of Friction —By Pedro J. Dozal, C. E., Escuela Nacional de Ingenieros de Mexico. Done into English by R. T. Mulleady, B.Sc. Eng. (Birmingham.) Buenos Aires: The Author. Cloth; 7 x 10 in.; pp. 155; illustrated.

SOME COMPRESSION TESTS OF PORTLAND CEMENT MORTARS AND CONCRETE CONTAINING VARIOUS PERCENTAGES OF SILT—By Arthur C. Alvarez and James R. Shields. Berkeley, Cal.: University of California. Paper; 7 x 11 in.; pp. 13; illustrated.

STORING: Its Economic Aspects and Proper Methods—By H. B. Twyford, Otis Elevator Co., Author of "Purchasing: Its Economic Aspects and Proper Methods." New York: D. Van Nostrand Co. Cloth; 6 x 9 in.; pp. 196; illustrated. $3.50.

SURFACE WATER SUPPLY OF THE UNITED STATES—Nathan C. Grover, Chief Hydraulic Engineer. Washington, D. C.: U. S. Geological Survey. Paper; 6 x 9 in.; illustrated. No. 432: 1916. Part II. South Atlantic and Eastern Gulf of Mexico Basins; Guy C. Stevens and Warren E. Hall, District Engineers. Pp. 53. No. 435: 1916. Part V. Hudson Bay and Upper Mississippi River Basins; W. G. Hoyt and A. H. Horton, District Engineers. Prepared in coöperation with the States of Minnesota, Wisconsin, Iowa and Illinois. Pp. 204. No. 441: Part XI. Pacific Slope Basins in California, H. D. McGlashan and F. F. Henshaw, District Engineers. Prepared in coöperation with the State of California. Pp. 330. No. 465: Hawaii, July 1, 1916, to June 30, 1917; G. K. Larrison, District Engineer. Prepared in coöperation with the Territory of Hawaii. Pp. 184. No. 428: Artesian Waters in the Vicinity of the Black Hills, South Dakota; by N. H. Darton. Pp. 62.

THE UNITED STATES GEOLOGICAL SURVEY: Report of the Director to the Secretary of the Interior, June 30, 1918—Washington, D. C.: U. S. Geological Survey. Paper; 6 x 9 in.; pp. 154; illustrated.

Society Service

A Section Dealing with the Results of Teamwork by Technical Men

"Service Bureau" Established by San Francisco Societies

In San Francisco there has recently been established an "Engineers' Service Bureau" which is intended to serve as a clearing house through which engineers in search of employment may get in touch with prospective employers and through which employers may find technical men promptly, as they are needed. This bureau is being conducted at the San Francisco Engineers' Club through the Joint Council of the San Francisco engineering societies. In this organization are represented the local sections of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the American Society of Mining Engineers and the American Chemical Society.

The bureau is to be provided with as complete a list of engineering vacancies as it is possible to compile, and endeavor will be made to keep this list up to date. Applicants are to state their qualifications and experience on blank forms which are to be sent in by mail. As these applications come in they will be compared with the "Engineers Wanted" list. If a call is found for a man with the qualifications given, the applicant will be notified at once. Otherwise, his application will be filed without acknowledgment, awaiting a call. The bureau is to give information only by mail or telephone; no applicants are to be received in person.

Notice of the establishment of the bureau has been sent to more than a thousand engineers on the mailing lists of the several local sections, and every effort is being made to encourage the support of the individual members. It is felt that if the general coöperation of the members is secured in the matter of reporting vacancies, the bureau will be able to handle applicants effectively, and the plan can be made permanent. Positions to be included within the field of the bureau's activities are such as "could be filled by civil, mechanical, electrical, mining or chemical engineers, inspectors, construction superintendents, assayers, surveyors, draftsmen, or, in general, men with technical training and experience in the fields of the five societies represented."

Minnesota's Inclusive State Society Nearing Organization

Following the Engineering Council's suggestions—for greater coöperative activity—as sent out to the various engineering societies and brought to many organizations in person by the secretary, A. D. Flinn, the Engineers' Society of St. Paul, Minn., has had a special organization committee working on a plan for a state society. It wanted one that could function more surely and serve the engineers and engineering societies in a better way than has the Minnesota Joint Engineering Board, if possible, although that body has probably done more effective work than any similar organization in the country. Note was made of the original move in this column, Dec. 19, 1918, p. 1141, but a later *Bulletin* of the affiliated Engineering Societies of Minnesota indicates changes from the original tentative proposal.

It is felt that the name Minnesota State Polytechnic is not so good as Minnesota United Engineering Society, for the word "Engineering" should not be omitted. Eight sections are proposed: Electrical, mechanical, mining, structural, highway, drainage, municipal and railroads. Each member shall be enrolled in one or more sections, but vote in but one. Societies would become associated with the state organization, and the members would become, automatically, members of the larger body. In addition, any engineer with the necessary qualifications residing or practicing in the state may become a member. A somewhat complicated system of government of the affairs of the society is proposed, but with the idea of representation according to the different branches of engineering, and not in any respect according to local societies.

An annual convention is to be held at which any one or more sections may have separate meetings for technical papers and transact business pertaining to the section.

A business meeting of elected delegates is to take place, and a general program is to be provided by the board. Delegates are to be elected as follows: Each section shall elect a member of the Minnesota United Engineering Board, which member shall be one of the delegates of that section at the annual business meeting. Each section shall also elect one delegate-at-large to the annual meeting.

Each associated society shall elect one delegate-at-large to the annual business meeting for each 50 of its membership, provided it shall be entitled to one delegate if it have but 30 members.

The officers of the Minnesota United Engineering Board shall be the corresponding officers of the Minnesota United Engineering Society, and with the other members of the Minnesota United Engineering Board shall constitute the board of directors of the Minnesota United Engineering Society.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Drainage of Irrigated Land

Sir—In connection with the article on the Imperial Valley seepage case, on p. 237 of the issue of Aug. 1, 1918, and your editorial on the same subject in the issue of Aug. 8, I desire to call attention to another phase of the problem.

It is a well known fact that, in time, portions of nearly all irrigated lands will become water-logged and alkalied to such an extent as to preclude the possibility of profitable farming on the affected areas. It is

conceded that, in general, this water-logging is due to the rise of the ground water. All waters going into the ground beyond those used by plants or evaporated from the soil tend to raise the ground-water level in the low places. These waters may include seepage losses from reservoirs, transmission losses in main canals, laterals and farmers' ditches, deep percolation losses from irrigated fields and waste water allowed to run into sink holes and low places, from which it slowly seeps away into the ground water. As a rule, deep percolation losses from irrigated fields constitute the largest factor in water-logging soils.

Thus it is evident that, in a majority of cases, it is impossible to ascribe the damage to any particular one of these parts of the irrigation system. As a matter of fact, all, or nearly all, of these sources are usually present, and it can be said truthfully that the damage is done by the whole irrigation community, including those using reservoirs, canals, laterals, higher lands and lower lands alike.

When any considerable area of land in a district has become water-logged, two courses are open to the owners. They may abandon them either partly (by devoting them to pasture) or wholly, or they may drain them. In each case these owners may shoulder the whole burden or it may be distributed. In the first case they may suffer the loss with as good grace as possible, or they may attempt to reimburse themselves for their loss by suing the owners of higher lands or canals, as in the Imperial Valley case. This is always expensive and the results are doubtful, to say the least.

In the second case the drainage may be done by the owners of wet lands, either singly or through some organization which includes only owners of wet lands, or it may be accomplished by the organization of a drainage district taking in not only the wet lands but the higher contributing lands, including the canals.

Several of the Western states have made provision through the enactment of suitable drainage district laws for the formation and administration of such districts. The Idaho law provides that higher lands and canals may be assessed for part of the cost of constructing drainage systems in proportion to their responsibility for the damage. This provision has been upheld by the state supreme court, both as to higher irrigated lands and as to canals. (Burt vs. Farmers' Coöperative Irrigation Co., 30 Idaho, 752). There are similar provisions in the laws of Montana, Oregon and Washington.

The tendency in Idaho is toward assessing the costs, in districts where all the wet lands have become so as a result of irrigation, at a flat rate per acre over the whole district. Such a flat rate for drainage costs in an irrigation district was recently upheld by Judge Isaac F. Smith in the seventh judicial district of Idaho.

The method of solving the seepage problem by draining the wet land and apportioning the cost over all the lands contributing to its water-logged condition has a number of advantages. It restores the land to a condition permitting a high state of cultivation, instead of allowing it to become mosquito-breeding marsh or an alkali-covered waste. It prevents the loss of home and improvements by the unfortunate owner of lower-lying lands. It divides the cost of reclamation among all those who have contributed to the damage, instead of making the owner of the low land pay the total cost of reclamation in addition to the loss of the use of the land during the interval, often long, between the time when the land becomes water-logged or alkalied and the time when it is reclaimed by drainage.

With the provision that such districts must not be constructed unless the enhanced value which will accrue to the lands of the district will exceed the cost of drainage, including organization and construction, there seems to be no danger that this solution of the problem will retard or cripple the irrigation development of the West. In fact, it should help that development, as it provides a feasible and equitable way of restoring the fertility of water-logged lands.

M. R. LEWIS,
Irrigation Engineer.
Boise, Idaho.

Problems Before American Society of Civil Engineers

Sir—Referring to the discussion of the problems before national engineering societies: I am summing up here the recent arguments I have heard. There is some uncertainty as to whether or not the governments of the national engineering societies are now supported by majorities such as are generally presumed to determine policies and carry them into effect. It has yet to be proved that any society can live indefinitely when its nourishment is limited to things technical.

By "society" we may mean (1) the collective body of persons forming a community, or the aggregate of such communities; (2) any body of persons connected by acquaintance, friendship or neighborhood, or associated for a common object; (3) the more favored class or classes or the fashionable portion of a community; the term "society" is then often used attributively; and (4) association in social relationship, fellowship, or companionship.

Our national engineering societies were doubtless organized under the theory set forth in definition 2—that is, "persons associated for a common object." The pioneer members of the society felt the need for an organization which would permit them to exchange ideas relating to engineering theory, design and construction. In their time, scientific research and investigation were sorely needed. The necessity for great activity in this kind of work on the part of the society has decreased as other agencies, better organized and better qualified to assume leadership, have come into being. The "common object" has remained practically unchanged, regardless of altered conditions.

The society has become more institutionalized, while its management is said to be less democratic, than during the earlier years of its history. The engineer has not given much study to the meaning of the words "civil engineer." The engineer who has tried to frame a registration law for civil engineers appreciates how difficult it is to define these words clearly. Yet we have all the machinery that any organization has evolved for its business management. That we lack something that pervades the atmosphere of the American Medical Association, and even of the American Bar Association, is clear to the engineer who has studied the activities of those two societies.

The technical field of the civil engineer is so broad that it is difficult to arouse a general interest among the members of the society in the study or discussion of a paper of great merit, as it generally concerns an isolated branch of theory or practice. Able critics hold that the society has already lost its place as a leader in the technical field, and that it has fallen under the influence of an element that may be indexed under the third definition of "society." If a change has taken place, let it be hoped that it is of a kind to encourage evolution in the right direction. If the change tends toward a condition that may be described under definition 4, we have cause for a feeling of optimism.

The engineer is too ready to provide machinery and to set it going, and then to leave it, assuming that the plant will produce desired results. His societies are inclined to be technical and impersonal. He is, speaking generally, an individualist of a somewhat extreme type. He is seldom the first to suggest coöperation. His time is largely occupied by investigations of a technical nature. His study and his leisure reading are not likely to direct his attention to "society" in its broad sense. While he is presumed to live in an atmosphere that is saturated with the sentiment of democracy, his organizations have been inclined to become more autocratic in government.

Recently the officers of the national engineering societies—some twenty to thirty men—committed the entire membership of thirty thousand in support of legislation before Congress, without giving the rank and file an opportunity to express individual views. This does not smack of democracy. The engineer is to achieve greatness through service. Opportunities for maximum service may be somewhat clouded when the element that largely dominates the policies of organizations (presumed to be representative) centers at the financial and industrial metropolis of the country. If these governmental defects are common to the four Founder societies, each should clean house before the average member will take much interest in any plan which contemplates their amalgamation.

The growth of local chapters, or associations, of the American Society of Civil Engineers suggests a longing for personal contact among its members. While some of these local associations will doubtless indulge in technical discussion for a time, in imitation of the parent body, the members will ultimately discover, I believe, that another cause leads them to assemble at a local headquarters where men of common interests may become mutually helpful through social intercourse. If these local associations do not recognize the motive which prompts their organization, I predict that they will be short-lived.

It is evident that the local associations are ultimately to dictate the policies of the national society. All centers of population will provide opportunity for such associations, and when the number multiplies to the point where a majority of the members are identified with one of the smaller organizations, the parent society must step aside and submit to the commands of these groups. The business of the national society will then be transacted through representatives of the local associations—and New York, instead of being the national headquarters, will simply support a local association of its own and will cease to use the facilities of the society for the benefit of a local club, as it is now presumed to do by many who simply stand and wait.

An organization which manifests but little interest in human problems is not likely to enjoy the permanent, sympathetic support of its members. The civil engineer may argue that he performs his greatest service to society when he perfects the technical machinery of his own profession. This kind of argument appeals to the man who is content to be recorded as a technician, pure and simple. Such a man manifests no sympathy for his associates in the engineering field; he has no concern regarding the welfare of his neighbors; public interests never disturb him, and the word "altruism" is not to be found in his dictionary. A society made up of men of this type must be a drab affair. That such a society must slowly disintegrate as its members begin to obtain a vision of opportunity for higher service is apparent.

The prominent engineer of the near future must exhibit as much interest in the welfare of his associates as in his own business or technical success. Engineering will have a place among the real professions when engineers accept these broader responsibilities.

CLARENCE T. JOHNSTON,
Professor of Surveying, University of Michigan.
Ann Arbor, Mich.

Are Bridge Engineers Losing Their Heads On Unit Stresses?

Sir—The report of the Committee on Column Tests of the American Society of Civil Engineers appears to have caused some fright among bridge designers; for I notice that the Engineering Institute of Canada has lately published a "General Specification for Steel Railway Bridges" in which the unit stress for columns is given by the formula,

$$p = 12{,}000 - 0.3(l/r)^2$$

in which l = the unsupported length of the column in inches and r = its least radius of gyration in inches.

This is quite a sudden jump from the old standard formula,

$$p = 16{,}000 - 60l/r$$

The change indicates one of two things: Either that hitherto we have been overstressing compression members from 15 to 25%, or that there is going to be wasted a vast quantity of metal in the future.

Moreover, in making such a sweeping change in the compression formula the writers of the Canadian specifications were not consistent, because in Clause 47 they allow for the compression flanges of beams an intensity of

$$16{,}000 - 200l/b$$

In the case of railway stringers l/b is generally in the neighborhood of 10; hence the intensity of working stress is about 14,000 lb. As b is equal to about $4.5r$, for $l/b = 10$ we shall have $l/r = 45$. Substituting this in the Canadian column formula gives

$$p = 12{,}000 - 0.3(45)^2 = 11{,}400 \text{ lb.}$$

In the case of one compression member of a bridge, it appears to be legitimate to stress the metal up to 14,000 lb. per square inch, and in another up to only 11,400 lb. per square inch, a difference of 23 per cent. And

there is no valid reason for stressing differently a strut which forms a part of the top chord of a truss and a strut which forms a part of the top flange of a beam. "Consistency, thou art a jewel!"

If the correctness of the formula for compression flanges of beams be conceded—a formula which, for a dozen years or more, has been one of the clauses of the American Railway Engineering Association's standard bridge-specifications, and which the Engineering Istitute of Canada has appropriated without change—and if it be granted that b is generally equal to about $4.5r$—why should not the equivalent formula,

$$p = 16{,}000 - 44l/r,$$

apply in general to struts with fixed ends? Be it noticed that this formula gives higher results than does my old formula,

$$p = 16{,}000 - 60l/r.$$

The American Railway Engineering Association is getting ready to trim down materially its old intensities for steel struts, although not to the extent that the Engineering Institute of Canada has done.

What aggravates the effect of this proposed decrease of compression intensities is that, simultaneously therewith, the American Railway Engineering Association is contemplating increasing its tensile intensity of working stress from 16,000 lb. to 18,000 lb.; and other specification writers are advising that it be made as high as 20,000 lb. To an outsider it must look as if the bridge engineers of this country were losing their heads!

The compression tests that started the present wave of apprehension did not have governing conditions corresponding properly to those of actual truss-members; hence I would suggest that, before the bridge engineers of America take the drastic step of assuming steel in compression to be only 60 or 70% as strong as the same material in tension, some really practical tests of struts be made under conditions corresponding to those in actual structures. Such a series of tests would cost considerable money; but, if the Bureau of Standards at Washington were to indorse the suggestion to make them, it ought not to be at all difficult to obtain from Congress an ample appropriation for the purpose.

The method of conducting these tests that I have in mind is this:

Let there be built a five-panel riveted-truss bridge of about 100 ft. span; let the middle panel-lengths of the top chords thereof be made decidedly weaker than all the other portions of the structure; and let a uniformly distributed live load be applied at the panel-points by hydraulic pistons. All portions of the structure, including the two weak members, should be scientifically detailed, so that failure will inevitably take place in the main portions of the weak struts and not in the details thereof, and so that the bridge can be used for a long series of tests to destruction of the said mid-panel lengths of the top chords. The weak members should be attached to the connecting plates with an ample number of rivets to develop the full strength of the test pieces; and these rivets should be removed carefully after each test to destruction is completed.

Of course, it would be entirely practicable to vary the value of l/r in the different tests, provided that the attachment of the test-strut be not made eccentric.

There should be a supporting platform beneath the span to prevent its falling any material distance when failure occurs.

By adopting a weak vertical post instead of a weak panel-length of top chord, and by loading (at the elevation of the latter) three panel-points only, a series of tests could be made on vertical posts. A similar series could be carried out on the inclined end posts.

A cheaper method than that just described, but not quite as satisfactory, would be to build a single truss, instead of the complete span, and steady it laterally but not vertically, and then to apply the test loadings directly above the top chord at the panel-points. A great advantage of the span tests as compared with the truss tests is that duplicate tests could be made simultaneously on similar members. Moreover, the span tests would be in practically exact accord with actual conditions of loading, while the truss tests would not.

By removing occasionally the test loading, the elastic limits of the struts could be ascertained through noting the absence or otherwise of permanent set.

Experiments similar to those described could be made on a pin-connected span or a pin-connected truss so as to determine the strength of struts with hinged ends.

In view of the immense amount of bridge manufacture and construction that is likely to be done in the United States within the next five or ten years, the making of this proposed series of tests is worthy of being considered a matter of national importance.

J. A. L. WADDELL,
Kansas City, Mo. Consulting Engineer.

International Language for Modern Engineers

Sir—Some years ago, during a voyage across the Pacific Ocean, I became acquainted with an English naturalist who jokingly defined the American engineer as a "most migratory species of mammalia." No wonder that among the engineers one may find many who know or study foreign languages—Spanish, German, French, even Chinese or Japanese—and not a few who can read, write and speak in Esperanto.

I never will forget my surprise when, in 1915, during the world exposition at San Francisco, I approached a group of gentlemen talking Esperanto, and found that more than half of them were engineers; as far as I recollect, among that group were H. Babcock, of the Southern Pacific Co.; F. G. Cottrell, mining engineer now at Washington, D. C., occupying an important post in the Bureau of Mines; a civil engineer with a difficult Slavonic name, and Professor Languel, mechanical engineer and professor of mechanics at the University of California.

No doubt readers of *Engineering News-Record* use or know this international language and might be interested in the only technical journal published in Esperanto, edited by Dr. R. Saussure, grandson of the renowned scientist H. Saussure who made the famous exploration of Mont Blanc in 1787. The name of this monthly is *La Teknika Revuo* (10 Hotel Glasse, Berne, Switzerland; annual subscription 5 francs, less than a dollar). The first number was published in July, 1918. The reading matter is subdivided into the following sections: Editorial; science; industry and commerce;

international associations, and technical dictionaries. It also includes a list of the 20 periodicals published at present in Esperanto in different countries. Among them we find Amerika Esperanto, West Lynn, Boston, Mass.

Knowing from my own experience how Esperanto is useful during travel and for obtaining first-hand technical information in foreign lands, I sincerely believe that any engineer who is too busy to learn several foreign languages will be benefited immensely by familiarizing himself with Esperanto, which he can acquire in his spare minutes of relaxation from routine professional work. At the same time Esperanto will enable him to come in contact with any foreign country, through the agencies or Esperanto delegates whose names are printed regularly in the Esperanto Year Book. Further information may be obtained from the Esperanto Association of North America, West Newton, Mass.

CIVIL ENGINEER.

Washington, D. C.

Spacing of Rivets in Lateral Bracing

Sir—The accompanying tables show the spacing of rivet holes for lateral bracing angles, giving a clearance of ½ in. between angles or between angles and chord.

These tables, while very simple, are not found in handbooks, and greatly facilitate the design of lateral systems.

SPACING OF RIVET HOLES FOR LATERAL BRACING ANGLES TO GIVE ½-INCH CLEARANCE

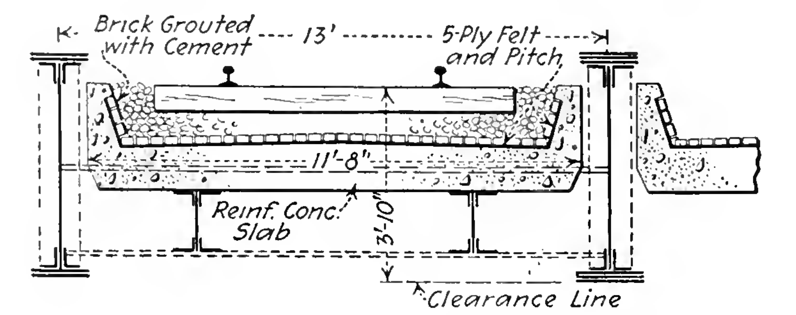
Thinking they may be of interest to designers, I have taken the liberty to forward them for publication, knowing that thus they would obtain wide circulation.

Dayton, Ohio. EDMUND FELDMAN.

Concrete Trough-Slab Floor Construction for Railway Bridges

Sir—In the discussion of waterproofed railroad bridge floors by H. T. Welty, in your issue of Dec. 12, p. 1081, a type worthy of note is not mentioned. This is the construction, shown by the accompanying sketch, in which the track is carried in a reinforced-concrete trough which is separate from the girder. The trough is supported by longitudinal beams under the rails. The vertical distance required from underneath the clearance line of the girder to the base of the rail is 3 ft. 10 in., or about the same as is required for the more recent designs of those described by Mr. Welty.

My observation has been that where concrete floors are finished against the girder the most careful applica-



REINFORCED-CONCRETE BRIDGE TROUGH NOT FINISHED AGAINST THE GIRDERS

tion of waterproofing material and the most careful attention to details will not insure complete success. In a series of bridges, some will be altogether tight, and others will show a slight discoloration on the under side, usually at columns. These defects do not pass water through in any appreciable amount, and are of no disadvantage from the point of view of the users of the street under the bridge. But they are serious in that a slight percolation of water to the fabric of the bridge endangers the structure, and means that the chief function of the waterproofing, to protect the steel, has not been accomplished. An unpleasant feature of this situation is that no information can be had as to whether the bridge is safe or unsafe, covered as it is by concrete.

In the design shown by the sketch the bridge members are all exposed and are protected by paint. There is no difficulty about the waterproofing. In fact, the brick and felt protection shown could in many cases be omitted.

JERVIS VAIL,
Assistant Engineer, Pennsylvania Railroad.

Rahway, N. J.

Heavy Road Traffic in Colorado

By a census taken under the auspices of the Colorado State Highway Department, the Santa Fé Trail is shown to have carried a traffic of 24,900,000 ton-miles. The next heaviest section in the state, the roads between Pueblo and Colorado Springs, carried 17,300,000 ton-miles.

Hints for the Contractor

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

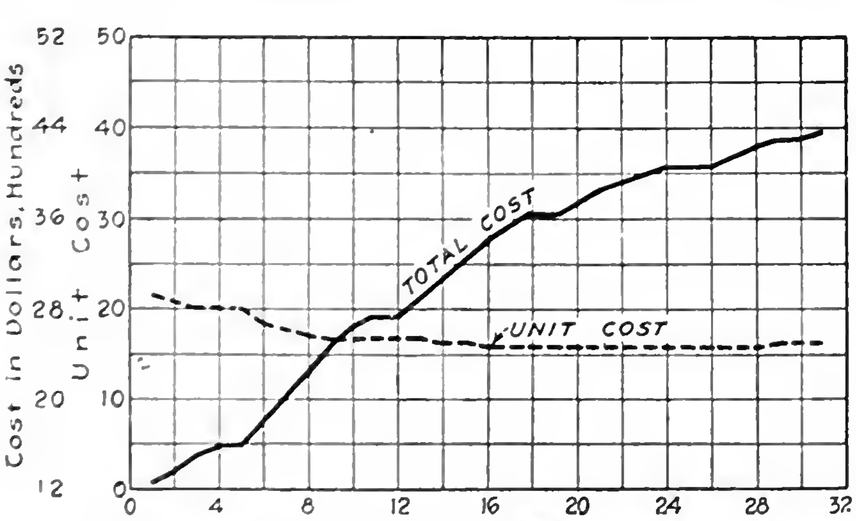
Only Completed Work Counts in Monthly Estimates

THE mixer was operating at possibly quarter capacity on a certain construction job. Only a part of the regular crew had reported for work that day. Such occurrences were not unusual last summer, when war industries were clamoring for workmen, and contractors had to be prepared to make the best of them. In this particular instance the contractor could have shut down the mixer and sent the men home. He could, if there had been opportunity, have transferred the men to other gangs. He could have put the men at work trimming stock piles or cleaning around the mixer, or otherwise marking time.

He did none of these things. Instead, he put the men at work operating the mixer and placing concrete at such speed as they were able. Obviously, the plant was not working economically. The contractor knew this. But he pointed out that, on the other hand, work which was being done was work which would count as money when the monthly estimate was made up. The incident is not very important in itself, but it exemplifies an important truth: Volume of construction completed is the only thing that counts in the contractor's monthly estimate. C. S. H.

Simple Chart Provides Complete Labor Cost Analysis

TWO curves record labor costs for construction performed by the Detroit Edison Co., as shown by the sample chart reproduced herewith. By a series of simple computations, using data read from the curves, a dozen facts of direct utility in checking construction costs and in estimating the cost of prospective work



LABOR COSTS FOR CONSTRUCTION SHOWN BY CHART

may be deduced. In fact, states William M. Ferguson of the Detroit Edison Co., in the *Synchroscope*, the curves furnish on a few sheets facts which reflect conditions of the work which would not be noticed in a lengthy report nor be seen by looking the work over in the field.

From the total cost curve can be read directly the total cost of the job at any time during the progress of the work. The second curve shows at any date the cost per unit of material placed—as, for example, the cost per cubic yard of concrete or per thousand of brick. It is obtained by dividing the total cost to date by the volume of material placed to date. The values for platting both curves are obtained from the time tickets each day, the backs of these tickets being used for reporting the amount of material used during the day's work.

Besides giving the total and unit costs at any date by direct reading, computation determines: (1) Total quantity of material, by dividing the total cost at any date by the unit cost as of the same date; (2) the cost for any day or the quantity of material placed for any day, by subtracting the total to date on the day previous from the total to date on that day; (3) the days of lost time, by counting the number of days that the total cost line extends horizontally; (4) the percentage, complete to date, by dividing the total quantity by the total estimated quantity multiplied by 100; (5) the percentage of work done from one date to another, by subtracting the totals at the two dates, dividing the remainder by the total for the whole job, and multiplying by 100; (6) the percentage of appropriation used, by dividing the total cost to date by the total estimated labor cost, and multiplying by 100. The unit time, or man-hours per unit of material placed, is another unit which may be obtained by dividing the unit cost by the rate per man per hour.

On the Detroit Edison Co. work the charts are kept by jobs, which are subdivisions of construction work orders; that is, each work order is divided into jobs according to the kind of material to be placed or the kind of work to be done.

Place Gravel Well Strainers in Shell

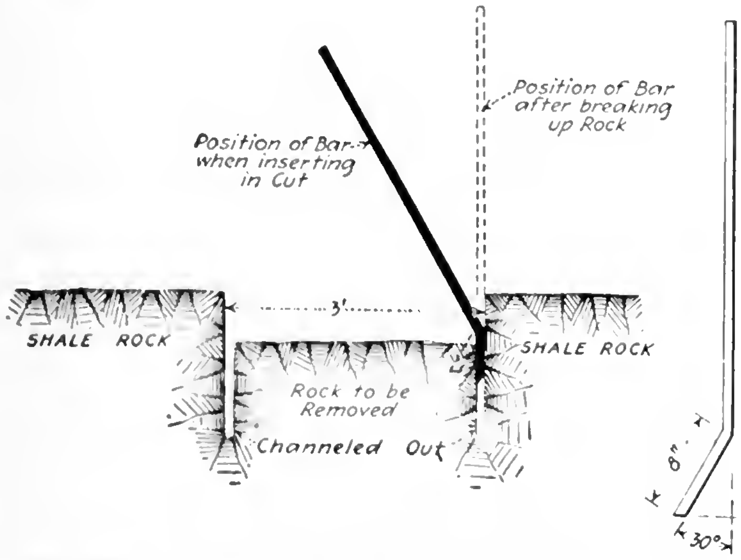
WATER for Camp Dodge, near Des Moines, Iowa, came largely from a 50-ft. circular open well 31 ft. deep, with the shell built of concrete, in which 30 strainers were inserted to permit water to enter from the sides as well as from the bottom. L. P. Wolff, in describing the engineering features of the camp in the *Bulletin* of the Affiliated Engineering Societies of Minnesota, states that the open well was constructed by building up the walls in sections above the water line, and then sinking them by excavating from the inside with a clamshell bucket operated by a derrick and hoisting engine. The bottom of the well was left about 5 ft. above the level of the blue clay. The strainers consist of openings in the wall filled with graded, screened gravel held in place with perforated cast-iron plates. Before being sunk, the screens were covered on the

outside with $\frac{3}{16}$-in. steel plates to prevent the entrance of the fine top soil, a cable being attached to each plate for the purpose of withdrawing it after the excavation was completed.

Bent Crowbar Easily Removes Shale Rock

BY G. W. MCALPIN
Point Pleasant, W. Va.

AN ORDINARY crowbar, bent back at the bottom for about 7 or 8 in. of its length to an angle of about 30 deg., proved a very useful tool in removing shale rock from a channeled key. As the key was narrow



ORDINARY CROWBAR, BENT, REMOVES ROCK

the rock was removed by hand, in preference to shooting. The bar was inserted in the channel cut and then pulled back. Thus the shale was torn up and its removal with shovels made possible.

Weed- and Root-Grubbing Implement Useful on Highway Maintenance

BY E. EARL GLASS
Monrovia, Cal.

A HOME-MADE combination hoe and hook has been used with excellent results in Los Angeles County, California, in clearing the weeds, sod and roots from the shoulders of the county highways. Combining two of the tools ordinarily used for this work, it not only

COMBINATION TOOL LOOSENS ROOTS, WEEDS AND SOD ON HIGHWAY SHOULDERS

reduces the number of pieces to be carted about the job but also saves considerable time which formerly had been consumed in changing from one tool to the other.

To make the implement, get a 16-in. piece of $\frac{3}{8}$ x $\frac{3}{4}$-in. steel and sharpen it at both ends. Then heat the steel to redness, bend it around the eye of a stout hoe and rivet it securely, as indicated in the illustration, which shows the tool in use on highway maintenance.

In operation, the tines formed by the bent steel serve to loosen gravelly soil, and are useful in removing tough weeds and roots and in hooking the loosened sod from the shoulders. A mattock, similarly fitted, has proved valuable for heavier work.

Home-Made Truck Supports Welding Outfit

BY E. EARL GLASS
Monrovia, California

TO FACILITATE the handling of a welding outfit, the small truck to support the apparatus, as shown in the illustration, was constructed from scrap by the shop men of the Los Angeles County Road Department. This addition to the welding outfit makes one-man operation and conveyance possible.

WELDING OUTFIT ON HOME-MADE TRUCK

To make the truck, parts were secured from several machines. The frame was obtained from an old steel bicycle rack, the wheels came from a discarded lawnmower and these were combined with the base and pipe handle to make a well-braced truck which proved very handy and useful as a support for the gas tanks.

Submerged Dividers Used on Concrete Walks

Submerged steel division plates were used on one-course concrete sidewalks constructed by the roller method at Donora, Penn. This method was described by W. M. Kinney, of the Universal Portland Cement Co., in *Engineering News-Record,* of June 20, p. 1196. The work was being done for the American Steel & Wire Co. on an extensive concrete housing development, requiring 25,000 sq.ft. of 5-ft. walk. The steel plates were $\frac{3}{16}$ in. thick, 5 ft. long and of a depth that would not project above the finished surface when in position. Where wooden forms were used, the plates were held in position by steel pins; where steel forms were used the plates had a special hook at the end which fitted into a prepared slot in the form. The concrete was filled to a depth of $\frac{1}{2}$ in. above the top of the plates and thoroughly rolled longitudinally, with the concrete roller. When it had stiffened sufficiently, the plates were removed by means of hooks, and the surface over the division line was grooved in the usual manner. A $\frac{1}{2}$-in. prepared bituminous expansion joint was placed every 50 feet.

NEWS OF THE WEEK

New York, January 16, 1919

F. S. Curtis, President of American Society

Engineer and Railroad President Elected at Annual Meeting In New York

Fayette Samuel Curtis, president of the Old Colony R.R., and previously vice president and chief engineer of the New York, New Haven & Hartford R.R., was elected president of the American Society of Civil Engineers at the annual meeting in New York this week. His experience in civil engineering in a period of over 40 years has been almost entirely in railroad work.

Mr. Curtis was born Dec. 16, 1843, at Owego, N. Y., and received his early education at the public and private schools of Owego, after which he took a course in civil engineering at Owego Academy. He began his engineering work in the summer of 1863, when he was employed by the Albany & Susquehanna R.R. Co. in the location and construction of a line between Binghamton and Albany. In 1866 he was engaged by the Southern Central R.R. Co. in railroad location and construction between Oswego and Auburn, and in 1869 rendered similar service for the Lake Ontario Shore R.R. between Oswego and Rochester. In 1870 he entered the service of the New York & Harlem R.R. as assistant engineer, and was engaged in surveys for the towns of Tremont and Fordham, now included in New York City. In 1871 he represented the Harlem River & Portchester R.R. Co. in the location of lines between New Rochelle and the Harlem River, and in the fall of 1871 was employed by the New York & Harlem R.R. Co. in the location of tracks and yards at the Grand Central Station, after which he was principal assistant engineer in the preparation of plans for and later in the construction of the Fourth Ave. improvement between the Grand Central Station and the Harlem River.

A few years later he was appointed chief engineer of the New York & Harlem River R.R. and superintending engineer of the Fourth Ave. improvement, continuing in the service of the New York & Harlem and New York Central & Hudson River R.Rs. until 1883, when he was appointed chief engineer of the New York, New Haven & Hartford R.R. He served as chief engineer of the New Haven until March, 1910, when he was elected fourth vice-president of the company, in general charge of the engineering department and other matters, with headquarters in Boston. Three years later he was promoted to the second vice presidency, but, owing to the large amount of en-

(Concluded on page 162)

American Society Passes Resolution Favoring Development of Public Works

Annual Meeting Also Indorses Action of Protest Against Dismissal of Engineers of Public Service Commission in New York

Disappointing in the fact that no discussion whatever was started on the report of the Development Committee, the annual meeting of the American Society of Civil Engineers Jan. 15 nevertheless passed two significant resolutions—one on the action of the Engineering Council in calling a hearing of protest in regard to the dismissal of engineers of the Public Service Commission of New York, and the other a strong resolution favoring the active and immediate prosecution of public works for the purpose of furnishing employment, especially to returning soldiers. The work of the National Service Committee in Washington was outlined and members were requested to offer suggestions.

New President of American Society of Civil Engineers

FAYETTE SAMUEL CURTIS

As was the case last year, the annual address by the president was read at this meeting, the summer convention having been omitted on account of war conditions. Pres. A. N. Talbot reviewed the activities of the society for the past year, and called attention to the vital part played by engineers in the war. A total of 1593 members, ranging from major generals and rear admirals down through the ranks, had entered the service. In addition, large numbers of members sacrificed financial and home interests to give their time to Governmental and war activities. In addition to reviewing the details, which will be found in the report of the Board of Direction, noted below, President Talbot stated that the John Fritz medal, awarded to J. Waldo Smith for his services in engineering and his achievement in providing New York with a supply of water, was the second award to a civil engineer, of the total number of 14 awards of this medal made up to this time. He mentioned the work of the American Engineering Standards Committee, and developed in detail many suggestive proposals for the future work of the society. An abstract of this address will appear in a later issue.

The Board of Direction reported a net increase in membership, for the year, of 343, not nearly as large as in some previous years, largely due to the greater number of losses by death, 109. The deaths of men in war service amounted to 18. The total membership on Jan. 1, 1919, was 8933. Three new committees were announced during the year: (1) The Committee on Development, consisting of one member appointed by each of the 22 local associations, and seven members at large appointed by the president; (2) The New York Meetings Committee, with authority to arrange for the second meeting in each month; (3) a committee of the Board of Direction appointed to keep it informed of any Governmental or other programs looking to reconstruction or rehabilitation of the engineering resources of the country after the war.

On Aug. 1 the 57th St. society house was leased to the Ajax Rubber Tire Corporation for 10 years, at a total annual rental of about $22,750. The present mortgage on the building being $200,000, at 6% per annum, the total net revenue will be a little less than $11,000 per year.

The year has been a difficult one financially for the society. If all bills incurred during 1918 had had to be paid by Dec. 31 the books would have shown a deficit of more than $20,000. The present financial condition is the result of several factors. A general estimate of the additional burden due to the unexpected conditions shows a total of $98,000.

The Committee on Award of Prizes reported the following awards: The Norman Medal to L. R. Jorgensen for

his paper, "Multiple-Arch Dams in Rush Creek, California"; the James R. Croes Medal to Israel V. Werbin for his paper, "Tunnel Work on Sections 8, 9, 10 and 11, Broadway-Lexington Ave. Subway, New York City"; the Thomas Fitch Rowland prize to F. W. Scheidenhelm for his paper, "The Reconstruction of the Stony River Dam"; the James Laurie prize to Charles W. Staniford, for his paper, "Unusual Cofferdam for 1000-Ft. Pier, New York City"; and the Collingwood prize for juniors to James B. Hays for his paper, "Designing an Earth Dam Having a Gravel Foundation With the Results Obtained in Tests on a Model."

The Nominating Committee for the coming year was elected as follows: District 1, J. J. Yates; District 3, F. P. Williams; District 5, J. F. Conway; District 6, N. F. Sprague; District 10, F. E. Weymouth; District 11, W. Fay Barnard, and District 13, H. L. Haehl.

The Special Committee on Engineering Education reported that after 12 years of work its final report was ready in the form of Dr. Mann's exhaustive studies, undertaken with the aid of the Carnegie Foundation (see *Engineering News-Record* of Oct. 24, p. 782). After sketching the history of technical education, Desmond FitzGerald moved that the president appoint a committee of three to confer with the committee of other societies to insure careful and general discussion of Dr. Mann's report. This resolution was referred to the Board of Direction and the special committee was discharged with thanks. Reports from other special committees showing the disruption caused by the war and the fact that little progress had been made were received.

The preliminary report of the Commitee on Development, printed in the December *Proceedings*, was accepted without discussion as a progress report.

It was announced that the Board of Direction had passed a resolution on the previous day, stating that it had considered the resolution passed by the Brooklyn Engineers' Club in regard to the summary dismissal of about 350 engineer employees of the Public Service Commission, First District, of New York State, and resolving that the dismissal of these employees was not only eminently unjust and an offense to the engineering profession, but directly opposed to the best interests of the City of New York and therefore to those of the country. It also resolved that the board recognize this to be matter upon which the Engineering Council has properly taken prompt action in calling a hearing of those directly concerned, which took place the same afternoon. It was moved and unanimously carried that the action of the board be approved by the meeting.

The following resolution was then offered by R. S. Buck:

"Whereas, it is vital to the peace and welfare of our country that during the necessary reconstruction period the number of unemployed be reduced; and whereas, the development of transportation, sanitation, power, and public utilities generally is necessary to the development and prosperity of the country; and whereas, the curtailment of needed public works during the period of the war has retarded the development of the country; and whereas, the speediest and most effective means to prevent the suffering, distress and demoralization resulting from unemployment is afforded by public works; and whereas, the public welfare and confidence upon which industry generally depends require that the construction of public works be vigorously prosecuted:

"Therefore, be it resolved that the American Society of Civil Engineers desires to record its profound conviction that public works should be carried forward to the fullest extent consistent with sound judgment, not only for fundamental economic reasons but for humanitarian reasons, to furnish employment for all who are properly entitled thereto, including our returning soldiers; and it is further

"Resolved, that copies of this resolution be forwarded to such Federal, state and municipal authorities as may be able, in the opinion of the Board of Direction, to promote the purposes of the resolution."

Marshall O. Leighton discussed the work of the National Service Committee, recently organized in Washington along the lines of the tentative plan offered by Philip N. Moore in the December *Proceedings*. As chairman of the committee, he asked for help and suggestions from members of the society. The office has been established in a small way in the McLoughlin Building, Washington, and the work is now being financed by the residue of the appropriation made to the Engineering Council last year. A resolution offered by Paul Hansell that it was the sense of the meeting that the four Founder societies should join in asking their members for a subscription of $5 each, to be handled as best seemed fit by the Engineering Council, was laid on the table.

The election of officers was announced, as follows:

President, Fayette Samuel Curtis, Boston; vice-presidents, to serve two years, Herbert Samuel Crocker, Denver, and Leonard Metcalf, Boston; for treasurer, to serve one year, Arthur Smith Tuttle, New York City; for directors, to serve three years, George Hallett Clark, New York City; Jacob Stinman Langthorn, New York City; Charles Clement Elwell, New Haven, Conn.; Willard Beahan, Cleveland; John Watson Alvord, Chicago, and Carl Ewald Grunsky, San Francisco.

At the afternoon meeting Brig.-Gen. R. C. Marshall, Jr., chief of the Construction Division, U. S. A., described in detail the work done in this country during the war.

Labor Department To Study Building Conditions

Division Organized To Collect Data To Be Used In Furthering Construction Campaign

(*Washington Correspondence*)

Preparatory to launching a campaign to encourage the resumption of all kinds of construction, the United States Department of Labor has organized a new bureau, called the Division of Public Works and Construction Development. The division, which is being directed by F. T. Miller under Roger W. Babson, chief of the Education Service, has employed the services of trained political economists and specialists in various fields of business, for the purpose of collecting and compiling definite information for use in furthering the nation-wide campaign for immediate general construction. The research work is being carried on under the general supervision of Dr. E. J. Clapp, professor of economics, New York University, and Dr. M. A. Mikkelson, editor of the *Architectural Record*.

Consulting Board Will Weigh Date

The research work includes the gathering of all data relating to construction, and the information so gathered and classified is to be submitted to a consulting board composed of representative business men with practical experience, who will weigh the facts and decide upon the merits and possibilities of such plans for construction as may be contemplated. The result is then furnished to those interested, through the publicity channels which have been adopted by the division.

The personnel of the Economists and Experts Branch has been carefully chosen to assure each specific field interested in construction being touched upon in the statistical estimates. Aiding Dr. Clapp and Dr. Mikkelson are Dr. Rufus S. Tucker, of Michigan University, and Dr. John Whyte, loaned by the New York University, who are engaged in land values research; Capt. Thomas W. Holden, instructor, Massachusetts School of Technology, investigating materials; Everett Domminick, New York City, in a consulting capacity, reporting on capital; E. L. Keesler, president of the League of Building and Loan Associations, in an advisory capacity; D. Everett Waide, Metropolitan Life Insurance Company, advisory; William M. Garland, president of the National Association of Real Estate Boards; E. J. Russell, director of the St. Louis Chamber of Commerce, estimating the demand for construction; A. P. Norton, statistician, Labor Department, statistics; Miss H. M. Sullivan, Chicago University, in charge of foreign precedent; Miss A. E. Hathaway, legal adviser; William B. King, of the National Federation of Construction Industries, and others who are lending their services to the work.

Specifically, the research branch has been asked to furnish all possible in-

formation as to the available supply of capital, the value of land, the cost of material, the supply of the various materials on hand, as well as the plant capacity for the production of these materials; labor, its supply, its efficiency and its cost; building construction now contemplated and held up during the war, and the demand for various classes of building in various sections of the country.

In connection with these, the economists and experts are amassing such other information as is brought to the notice of the division from time to time and which will aid in furnishing facts for publicity. This publicity will be handled through the newspaper press, the trade journals, correspondence and a speakers' bureau, the latter composed of men who have a thorough knowledge of the construction situation; they will work in coöperation with the chambers of commerce and other organizations.

To Promote Home Building

A poster campaign will be inaugurated to further the "Own-a-Home" campaign. These posters will be distributed throughout the country for display on new buildings, their purpose being to effect a closer feeling between workmen and contractors and to promote the home-building idea generally. The posters will be signed by Secretary of Labor Wilson.

In speaking of the financial plan contemplated by the division, F. T. Miller, in an interview with the Washington representative of *Engineering News-Record*, said that the logical means for bringing the construction campaign to an immediate working basis was through the building and loan associations. Mr. Miller stated that there were 7269 such associations in the United States, with a total membership of 3,838,612. Their total assets, he said, were $1,750,000,000, and their receipts for 1917 were $1,220,000,000. The cost of doing business, he pointed out, was $9,800,000, which amounted to only 0.8 per cent.

"What is necessary," Mr. Miller said, "to make it possible for these associations to aid in the Own-a-Home construction campaign, is to make their assets negotiable. If this can be accomplished—and I see no reason why it cannot—the financial problem has to a great extent been overcome."

Mr. Miller stated that he had no doubt as to the possibility of creating a demand for municipal bonds. These, he said, always have been, and are now, in demand.

The division is now sending out questionnaires to 15,000 contractors who have been compelled to discontinue building operations because of war conditions, requesting that they furnish information as to why the construction is not being completed.

Specific answers are requested relating to the cost of labor and material, and financial plans.

Walker D. Hines Is Made Director General of Railroads

The appointment of Walker D. Hines as Director General of Railroads to succeed W. G. McAdoo, resigned, was announced Jan. 11. Mr. Hines was graduated from Ogden College, and obtained the degree of LL.B. from the University of Virginia. Shortly thereafter he entered the railroad field as assistant attorney for the Louisville & Nashville R.R., at Louisville. He specialized in the study of interstate commerce laws, and in 1900 was appointed first vice president of the road. He left the Louisville & Nashville four years later and formed a law partnership with Alexander Humphrey. In 1906 he went to New York and was made counsel for the Atchison, Topeka & Santa Fé Ry. Soon thereafter he became chairman of the board of directors of the company, and later chairman of the finance committee.

When this country entered the war he resigned his offices with the railroad and went to Washington, where he became Assistant Director General of Railroads. He has been generally regarded by railroad men as Mr. McAdoo's right-hand man. Mr. Hines has definitely announced that he favors the continuation of Federal control of the carriers for a five-year period.

Work of Valuation Bureau Reported by Interstate Commission

Although the war interfered with the prosecution of the work of the Engineering Section of the Bureau of Valuation, the Interstate Commerce Commission reports that it still hopes to complete the field work in 1919. In fact, for the past year—up to Sept. 30, 1918—the road and track parties covered 53,244 miles of main track and 81,470 miles of all track, which is in excess of any previous year's record.

In view of the experience of the current year, the office work probably cannot be finished, as estimated, during 1920. It was more difficult to maintain that force, many more than 25 per cent. of the office employees in a given district changing during a single month.

While the land section has not seriously felt the effect of the war, it cannot produce completed reports until certain information is received from the carriers as to their land; inability to obtain this has limited the progress of this section. It is expected that this section will complete its work within 1920.

The greatest difficulty has been experienced by the Accounting Section in obtaining and retaining competent accountants, owing to demands for this kind of service, both by the Government and by private enterprises. It is difficult to find men competent to put the needed information into the form of completed reports. The field work of this section should be finished in the first part of 1920.

On the whole, it is believed that while the war has seriously affected this work, it will not greatly postpone the period of final completion nor increase the total expense.

Would Appropriate $100,000,000 for Land Reclamation

Expenditure of $100,000,000 by the Secretary of the Interior "for the investigation, irrigation, drainage, and development of swamp, arid, waste, and undeveloped lands," to provide "employment and farms with improvements and equipment for honorably discharged soldiers, sailors, and marines of the United States," is authorized by a bill now before Congress. The lands reclaimed would be so disposed of by the Secretary of the Interior as to reimburse the United States within 40 years from entrance by settlers, with interest at 4%. The money will be available to develop one or more projects in each state, if feasible projects can be found. The scheme is in line with recommendations made by Secretary Lane. Investigations of the kind contemplated are already being made by the United States Reclamation Service.

American Engineer Elected to L'Institut de France

J. A. L. Waddell, consulting engineer of New York and Kansas City, was elected, Dec. 17, to L'Institut de France as a corresponding member in the Académie des Sciences. L'Institut de France is composed of five academies, including the Académie des Sciences, which is restricted to a full membership of 66, all of whom must be citizens of France, and in addition there are 116 corresponding members in other countries. The académie is divided into several sections, including geometry, mechanics, astronomy, geography and navigation, and general physics. Dr. Waddell's election to the mechanical section fills the vacancy created by the death of General Zaboudski of Petrograd.

Fayette S. Curtis

(*Concluded from page* 160)

gineering work being done by the company at that time between New Haven and New York, it was necessary for him to assume personal charge, and in 1904 he moved his headquarters to New Haven. He served as vice president of the New Haven until April, 1907, when he was appointed president of the Old Colony R.R. Co. and the Union Freight R.R. Co. of Boston. Since that time his headquarters have been in Boston.

Some of Mr. Curtis' works, aside from those already mentioned, were the large drawbridge over Fort Point Channel, Boston; the South Terminal Station, Boston, of which he was consulting engineer, and double-tracking and grade-crossing improvement work on many sections of the New Haven.

Railroad Executives Favor a Department of Transportation

At a meeting held in Philadelphia Jan. 5 the Association of Railway Executives unanimously adopted a plan calling for the creation of a Department of Transportation, headed by a Secretary of Transportation, who would be a cabinet officer and to whom would be transferred the administrative functions now performed by the Interstate Commerce Commission. Among other principles for an elaborate revision of existing railroad control legislation, the plan includes the following:

Private ownership, management and operation should, as a matter of national policy, be continued.

The power of regulation, including all rates, state or interstate, should be exclusively in the hands of the national Government, but administered through machinery or agencies responsive to the needs of and convenient to the people of the several states.

The carriers should have the power to initiate rates.

The statute should provide the rule of ratemaking, and should require that rates be not only what has been called reasonable but adequate and sufficient. Rates, whether approved or disapproved by the Secretary of Transportation, may by complaint be brought before the Interstate Commerce Commission, which should have power to pass upon the reasonableness and adequacy thereof.

The Interstate Commerce Commission should have power to prescribe minimum rates as well as maximum rates.

Other provisions are submitted covering in detail the questions of rates and the required modification of the Clayton act, the control of securities and a system of Federal incorporation. Thomas DeWitt Cuyler is chairman of the standing committee of the railroad executives.

Honor Resident Engineer of Army Supply Base at Boston

A dinner was given in honor of George L. Mirick, resident engineer of the Boston Army Supply Base, at Young's Hotel in Boston, Jan. 3, by the engineering staff of Fay, Spofford & Thorndike, consulting engineers, Boston, in recognition of his services on the work. Among those who attended were John Ayer, executive engineer of the supply base; Warren D. Trask, assistant division engineer attached to the field office; Capt. George D. Emerson, Quartermaster Corps, who was in charge of inspection; Carroll A. Farwell, division engineer in charge of substructure design; Bion A. Bowman, division engineer in charge of superstructure design, and Barzillai A. Rich, division engineer in charge of equipment.

The dinner was followed by expressions of appreciation of Mr. Mirick's work as resident engineer.

Engineering Council Holds Hearing on Public Service Engineers' Dismissal

Facts as to Crippling of Rapid-Transit Work Presented—Delegate Protests On Score of Workers' Safety—Mass Meeting Asked

A hearing on the mass dismissal of engineers of the Public Service Commission of New York State, First District, was held Jan. 14 by a committee of the Engineering Council at the Engineering Societies Building, New York. Commissioner Travis H. Whitney, representing the commission, which had been invited to the hearing, stated the situation. More details of how the work of design, construction and supervision is affected were given by Robert Ridgway, acting chief engineer; A. I. Raisman, engineer of design; C. M. Holland, tunnel engineer, and C. F. Smollin, chief clerk. The Board of Estimate, which had also been invited, was not represented.

Figures on the depletion of various branches of the engineering organization were given—the total engineering force of 812 being reduced by 334—and it was stated that in view of the serious responsibilities involved it had been concluded that the only possible course is to concentrate the available men on the contract sections most urgently in need of being carried on. This necessitates stopping work on the other sections. Questions of the committee developed the fact that this procedure will inevitably subject the city to direct losses as well as to contractors' claims of damage for delay. At present contracts amounting to about $80,000,000 are outstanding, on which $60,000,000 has been paid; the latter sum therefore represents capital lying idle in case work is delayed.

Work has had to be stopped on the preparation of designs for a large number of important contracts planned to be let during the coming season, such as the Nassau St. line and the Steinway tunnel extension. Approval of working drawings on present contracts has also been interrupted. The chief design divisions have been cut to one-third or less of their necessary minimum complement.

The committee displayed interest in the statement that the conduct of the river tunnel work and certain other operations represented a grave situation in view of the reduction in engineering force. It then concerned itself particularly with the question whether the cut in appropriation and the fixing of a detailed schedule of positions and salaries had been preceded by hearings, or by conferences between the commission and the board. Commissioner Whitney stated that no hearings or conferences had taken place.

It appeared that the action taken was based on little or no knowledge of the requirements of the rapid-transit work, and that the schedule, which ignores civil service laws and contains many faults and inconsistencies, was prepared by a subordinate of the Board of Estimate of the city and had not been scrutinized by the board.

A strong statement was made by M. McConville, a delegate from the Hoisting Engineers' Union, who asserted that the workers' safety depended on engineering supervision and protested against the reduction of the engineering force by the board.

Resolutions of protest passed by the Brooklyn Engineers' Club, by the American Society of Civil Engineers, and by the Municipal Engineers of New York, were read to the committee by representatives. The General Contractors' Association, the Merchants' Association and the Chamber of Commerce were represented.

J. C. Meem, speaking from the viewpoint of the contractors, forcibly expressed their sympathy with the protest against crippling the engineering supervision of public work.

In opening the hearing, H. W. Buck referred to the development of engineering public opinion in recent years as a new force, and said that the hearing was a step in bringing that opinion to bear on the case in hand.

A plea for more emphatic and representative development of the profession's public opinion was made by E. J. Mehren, editor of *Engineering News-Record*, at the close of the proceedings. He urged the value of a mass meeting of New York engineers, to be called by the council, if the facts developed at the hearing appeared to justify further action.

Seattle To Buy Street Railways

Municipal ownership of the street railways of Seattle, through purchase from the Puget Sound Traction, Light & Power Co. for $15,000,000 of city bonds, is authorized by an ordinance passed by a 5 to 2 vote of the city council Dec. 31. The property includes 203 miles of track and 540 cars, besides carhouses, repair shops and supplies. A referendum vote on the purchase is a possibility but is not expected, for in November last the general plan was approved 4 to 1 on an "advisory" popular ballot. The city and company officials have agreed on a friendly suit to determine the legality of the transaction. It is hoped that the property will be transferred to the city by Mar. 1.

Mining and Electrical Engineers to Hold Joint Meeting

It is planned to hold, at the annual meeting of the American Institute of Mining Engineers, in New York, Feb. 17-20, two joint sessions with the Canadian Mining Institute Feb. 18, and one joint session on the afternoon of Feb. 19 with the American Institute of Electrical Engineers.

Would Give Supply Men More Recognition

Changes in New England Water-Works Association Customs Suggested by President Davis

More recognition of both the younger and the associate members of the New England Water-Works Association was suggested by Carleton E. Davis, retiring president, in his address at the annual meeting of the Association in Boston, Jan. 8. Before reaching this part of his subject Mr. Davis touched on services rendered by water-works during the war and the opportunities for still further service during the reconstruction period. In closing, reference was made to the annual award of the Brackett memorial. A condensation of the address follows:

"Water-works officials may feel legitimate pride that the utilities under their direction responded generally to the public necessities of the war period in a satisfactory way. Probably no other essential to the prosecution of the war suffered fewer breakdowns and caused less concern to the consumer than did the water-works, notwithstanding that they, equally with other public-function activities, were handicapped by the general difficulties of the situation. The period of reconstruction has now come. Out of the present situation will come whatever those who are able to form and direct may desire.

"The association will grow according to the service it renders. There is an opening for a new field of usefulness in the development of the headquarters force, so that any person anywhere desiring information on water-works subjects would think naturally of the New England Water-Works Association as the source to which to apply. Such service would bring returns in increased membership, wider circulation of the *Journal* and greater advertising value for its pages.

Younger Men Should Come to Front

"Perhaps the younger members are not heard from as frequently as desirable. There is a natural gravitation of one age to a like age, and it may be that there has been an undue representation in the management of the association of the members of maturer years who may lack the necessary acquaintance among the younger men to bring out all their possibilities.

"The old-fashioned experience meetings are typical of the spirit of this association. They were good for the soul and good for the mind, and personally I hope it will be found proper to develop an increase in their number. They have been the means of placing at the disposal of the general water-works practitioner a vast fund of invaluable information concerning ways and means, and at the same time they have furnished a wonderful safety valve for pent-up feelings.

"Possibly the future may develop periodical meetings conducted by the associate members—meetings at which the present practice will be reversed and the associates will talk while the members listen. It may be that the associates are now obtaining an undue advantage in listening to the views of the members, pro and con, without being obliged to commit themselves to any line of action. On the other hand, perhaps the members are not availing themselves of an opportunity to hear a frank discussion between the various makers of the articles in everyday use by the water-works operator. Nothing could be more enlightening than a free discussion between makers of competitive goods, and doubtless such discussions could be brought about without detriment to any and with profit to all, apart from the features that may savor of competition. This same principle might be carried further with advantage and membership on committees investigating subjects in which the associates are vitally interested might be given them.

Half of Income from Associates

"One change which has already been effected by the war is open diplomacy and the adoption of perfect frankness and discussion. In following these lines, the association will doubtless reconstruct the present rather indefinite financial status of the associates. From dues and through advertising, the association derives about one-half of its income from the associates, and at the conventions accepts or solicits contributions for entertainments and hospitality. This is not solely a business transaction on either side. The association furnishes a medium through which personal relations are developed, to the mutual advantage of both parties having business to transact with each other. The situation should be frankly recognized and put on a definitely understood basis.

"A notable recognition of the wide range of activities embraced within the membership of this association is the award of the Brackett memorial for a paper devoted to accounting. The water-works operator has been too often classified as a specialist on pumps, pipes, reservoirs or some similar matter, while in fact he is responsible for not only the operation of highly specialized machinery, but he is further charged with the conduct of large business interests. By its own action, the association now lays claim to this larger sphere of operations and asserts the proper standing of its members in the community."

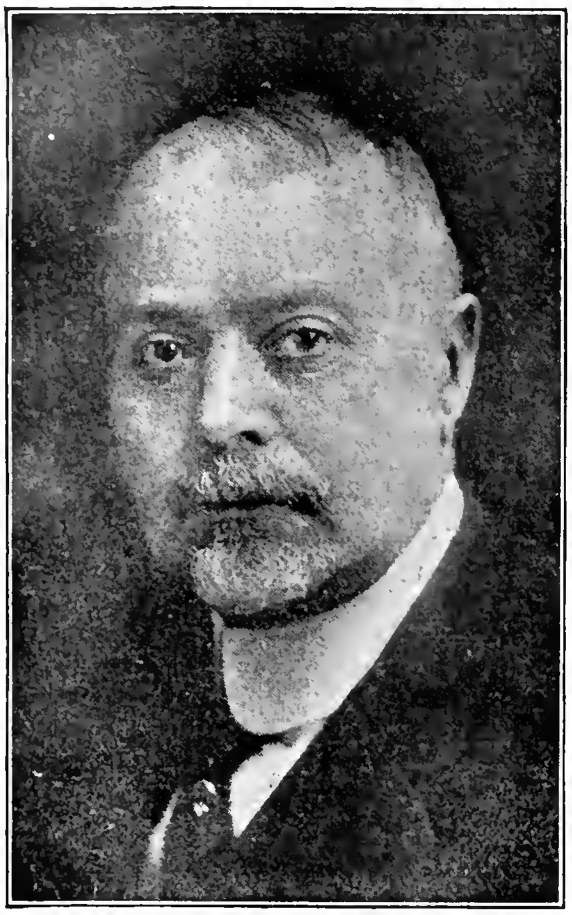
Business Proceedings

The canvass of ballots showed the election as president of Samuel E. Killam, superintendent of pipe lines and reservoirs, Metropolitan Water-Works, Boston, and the reëlection of the following: Secretary, Willard Kent, Narragansett Pier, R. I.; editor, Henry A. Symonds, consulting engineer, 70 Kilby St., Boston; treasurer, L. M. Bancroft, Reading, Mass.

Hermann Laub

Hermann Laub's death from heart failure on Dec. 10 took away an unusually able and versatile engineer. He ranked among the best bridge engineers in the country.

As builder of two important suspension bridges over the Onio River, at East Liverpool, Ohio (1896), and Parkersburg, W. Va. (1916), Mr. Laub had achieved the rank of leading



HERMANN LAUB, 1855-1918

authority on medium-span suspension bridges. Disagreeing with current teachings and practices, he held strong convictions of the merit of the suspension type for heavy street service, and through this conviction accomplished a distinct revival of the medium-span suspension bridge. He showed corresponding independence and vigor of thought in other fields.

Born Apr. 14, 1855, at Durmentingen, Württemberg, of Swiss ancestry, Hermann Laub studied civil engineering at the Stuttgart Polytechnic (1875) and the Munich Technical College (1870) and then removed to the United States. His engineering career in this country began in 1880, on the Denver & Rio Grande. For half a dozen years he was associated with Gustav Lindenthal in engineering practice. In 1890 he established an independent practice in Pittsburgh.

His structures include many notable works. Tasks of exceptional difficulty were often entrusted to him. An example was the salvaging and repair of the 22nd St. bridge over the Monongahela River at Pittsburgh in 1910.

A year or more ago Mr. Laub undertook to set down his views and experiences in the field of suspension bridges. This work remained unfinished at the time of his death.

Engineer Officers Decorated With Distinguished Service Cross for Services Rendered in This Country

MAJOR GENERAL GEORGE W. GOETHALS

MAJOR GENERAL WILLIAM M. BLACK

BRIGADIER GENERAL HENRY JERVEY

Cleveland Votes to Build New Union Station

By a vote of 31,000 to 20,000 approximately, the City of Cleveland on Jan. 6 adopted the ordinance authorizing the mayor to enter into a contract with the Cleveland Union Terminal Co. providing for the construction, maintenance and operation for the use of steam and electric railways of a union passenger depot adjoining the southwest corner of the Public Square. This contract when signed would, at the option of the railways concerned, serve to abrogate the previously signed contract between the city and the Pennsylvania, New York Central, Cleveland & Pittsburgh and Big Four Railroads for a union station on the lake front. The lake-front station plan was developed subsequent to the adoption of the Cleveland group plan, which provides for a Mall reaching from the lake front south to a point just east of the Public Square and lined on each side with public buildings. This building plan has already been started, and a number of public buildings are in place. The railroad station, however, has never gone beyond the project stage, the contract providing that work should start within six months after the delivery of certain deeds, which real estate deal has never been consummated.

The new union station scheme developed from a project to build a station for the Cleveland & Youngstown R.R., into which were later drawn the Wheeling & Lake Erie, the Erie, the B. & O., and the Nickel Plate, which latter had bought the Cleveland & Youngstown Railroad. The latter station was originally planned as a stub-end terminal lying south and west of the Public Square along the Cuyahoga River valley, and embraced freight terminals farther south along the same valley. When plans for this passenger station were submitted early in 1918 to the United States Railroad Administration it was suggested by the Regional Director that the plan be changed from a stub-end to a through-passenger station, with interurban electric terminal facilities, and that all the railroads entering the city be brought into the scheme. Later in 1918 the various railroads concerned came to an agreement to this end, and a report recommending a grand union station for all the railroads was adopted. This report brought about the introduction of the ordinance which has just been voted upon.

Although most optimistic newspaper reports come out of Cleveland to the effect that the new station will be immediately started, in fact there remain a number of difficulties, partly financial and partly legal, which have to be overcome before actual construction will be started.

A number of technical reports were made on the general feasibility of the new scheme and the desirability of one of the two schemes.

Nominations for American Railway Engineering Association

The nominating committee of the American Railway Engineering Association announces the following nominations of candidates for officers for the ensuing year:

For president, Earl Stimson, general superintendent maintenance of way and structures, Baltimore & Ohio Railroad; for vice president, J. A. Atwood, chief engineer, Pittsbugh & Lake Erie Railroad; for treasurer, George H. Bremner, district engineer, Bureau of Valuation, Interstate Commerce Commission, Chicago; for secretary, E. H. Fritch, Chicago.

Response to Inquiry Indicates Extensive Road Building

Road building will be undertaken on an extensive scale during the coming season, furnishing a large amount of work for returning soldiers, according to information obtained by the Bureau of Public Roads in response to an inquiry sent to the various state highway departments. Of the 38 states replying to the questionnaire, 29 gave definite figures. A summary of their reports shows that they can utilize 11,637 soldiers and sailors, as skilled laborers, and 91,904 as unskilled laborers. The bureau estimates that the total amount of road work in the United States for the coming year will be about $300,000,000.

In making its reports on road conditions to the newly formed Division of Public Works and Construction Development of the Department of Labor, the Department of Agriculture gave detailed reports from 20 states showing that $120,000,000 will be expended on road work which has definitely been decided upon. It is estimated that 50% of this amount will go to labor.

In commenting on these conditions, the Department of Labor urges that public works unquestionably needed should be put under way at once.

Engineering Societies

The Montreal Branch of the Engineering Institute of Canada was addressed Jan. 9 by George H. Greenfield, of the National Fire Protection Association, who spoke on "Fire Prevention."

Calendar

Annual Meetings

AMERICAN WOOD PRESERVERS' ASSOCIATION; F. J. Angier, Mt. Royal Station, Baltimore, Md.; Jan. 28-29, St. Louis.

AMERICAN ROAD BUILDERS' ASSOCIATION: 150 Nassau St., New York City; Feb. 25-28, New York City.

NATIONAL RIVERS AND HARBORS CONGRESS; 824 Colorado Bldg., Washington, D. C.; Feb. 5-7, Washington, D. C.

AMERICAN INSTITUTE OF MINING ENGINEERS; 29 West 39th St., New York City; Feb. 17-20, New York.

The Indiana Engineering Society, at the annual meeting to be held in Indianapolis, Jan. 23-25, noted in these columns last week, will give prominence to the general subject of the status of the engineer and the organization of engineering societies. Included in the list of subjects and speakers are the following: "The Engineer, His Problems and Opportunities," by W. H. Finley, president of the Chicago & Northwestern Railway Co., and president of the American Association of Engineers; "The Need of Coöperation Among Engineers," by C. E. Drayer, secretary of the American Association of Engineers; "Proposed Bill for Licensing Structural Engineers," by H. O. Garman and W. H. Insley, Indianapolis; "Developments of the Governing Policies for Engineering Societies," by Prof. A. N. Talbot, retiring president of the American Society of Civil Engineers. Highway and railroad problems are included in the topics for discussion.

The Detroit Engineering Society held a meeting Jan. 10 devoted to the subject of "Grade Separation." The meeting was addressed by Prof. Henry E. Riggs, of the civil engineering department, University of Michigan, and John W. Reid, grade-separation engineer for the city of Detroit. The society will hold a meeting Jan. 24, to be devoted to the subject "Artillery in War." The meeting will be addressed by an officer of the Ordnance Department of the Army.

The Engineers' Club of Philadelphia will be addressed by Lieut. Col. E. B. Morden, U. S. A., Constructing Quartermaster, Philadelphia, on "The Construction Division of the Army," at the weekly luncheon of the club, to be held Jan. 21.

The Rochester Engineering Society will hold a meeting Jan. 17, with "Old Surveys of Rochester" as the subject of discussion. This is to be the first in a series of group meetings on the subject of municipal surveys.

The Engineers' Club of St. Louis has elected officers for 1919 as follows: President, Baxter L. Brown; vice-presidents, George R. Wadleigh, W. E. Wolfe and H. W. Eales; treasurer, C. W. Martin; directors, George E. Chamberlin, J. L. Hamilton and W. W. Horner. J. W. Kerr is secretary.

The Engineers' Club of Trenton was addressed, Jan. 9, by Lieut. Col. George A. Johnson, Construction Division, U. S. A., who spoke on "The Operation of Army Camp Utilities by the Construction Division of the Army."

The Florida Engineering Society held its annual meeting at Jacksonville Jan. 6. In presenting the report of the Committee on Harbor Improvements, W. W. Fineren, United States junior engineer, United States Engineer's Office, Jacksonville, emphasized the need of municipalities taking a more active interest in developing the harbor facilities of Florida, and indicated many possibilities for expansion. In the report of the president of the society, emphasis was given to the lack of recognition for engineering service, including a statement that although engineers, by training and experience, are fitted for civic duties, they have in the past been seldom appointed to civic boards and commissions. The following officers were elected: President, B. Johnson, Miami; vice-president, G. B. Hills, Jacksonville, and secretary, J. R. Benton, Gainesville.

The Gas Engineering Section of the Western Society of Engineers was addressed by Prof. S. W. Parr, department of applied chemistry, University of Illinois, on "The Present and Prospective Status of the Gas Industry," at the first meeting of the section since its formation. The meeting was held Jan. 8. This section is one of the few strictly professional gas engineering organizations, and a campaign is being conducted to bring into the society additional membership among gas engineers.

Personal Notes

LEWIS NIXON, consulting engineer, New York City, has been appointed Superintendent of Public Works of New York State. Mr. Nixon was previously consulting engineer and acting commissioner of public works of the Borough of Richmond, New York City, resigning in 1915 to enter private practice. He was graduated from the United States Naval Academy at the head of his class in 1878 and later was sent by the Navy Department to the Royal Naval College, Greenwich, England. He was appointed naval constructor in the United States Navy in 1884. Several years later he withdrew from the Navy to become superintending constructor of the Cramp shipyard, Philadelphia. In more recent years he has been prominently connected with politics in New York State. In 1914 he became consulting engineer and acting commissioner of public works of Richmond.

G. H. DUGGAN, vice president and managing director of the Dominion Bridge Co., Montreal, has been elected president of the company.

MAJ. MYRON B. REYNOLDS, recently released from his command of the 208th Engineer Sappers, 18th Division, Camp Travis, Texas, has been appointed acting assistant city engineer of Chicago, succeeding Henry W. Clausen, who resigned Jan. 1 to enter private business, as mentioned in these columns last week. Major Reynolds was engineer of water-works design in Chicago for four years previous to his entry into Government service in September, 1917. He entered the city engineering department thirteen years ago.

HUGH RODGERS has been appointed to the position of city engineer of Salem, Ore.

RICHARD H. GILLESPIE, formerly chief engineer of the Borough of the Bronx, New York City, has been appointed chief engineer and general manager of the Dewey Cement-Gun Construction Co., with headquarters at Allentown, Penn.

CLARK DILLENBECK, engineer of bridges and buildings, Philadelphia & Reading R.R., has been appointed assistant chief engineer of the Reading, the Central Railroad of New Jersey, the New York & Long Island R.R., the Atlantic City R.R. and the Port Reading Railroad.

HOMER C. BENDER, previously of Berkeley, Cal., has been appointed superintendent of public utilities, Spokane, Wash.

R. A. BURNS has been appointed to the office of city engineer of Lewiston, Idaho.

F. O. DUFOUR, division of construction and engineering, Stone & Webster, has been appointed structural engineer, with headquarters at the main office in Boston.

MAJ. A. CLINTON KNIGHT, Corps of Engineers, U. S. A., who recently returned from overseas, has received his discharge from the service and has been appointed assistant engineer, city highway engineering department, Baltimore.

CHARLES M. WHELAN, hydraulic department, Aluminum Co. of America, Pittsburgh, has been transferred to the sales department of the company at Kansas City, Mo.

P. S. BAKER has been appointed engineer of bridges and buildings, Philadelphia & Reading R.R. and associated lines, succeeding Clark Dillenbeck, who has been appointed assistant chief engineer of the lines, as noted elsewhere in this column.

WAYNE A. PITTS, formerly vice-president of G. W. Ensign, Inc., engineer and contractors, Harrisburg, Penn., has resigned to become plant

engineer for the York Haven Paper Co., York Haven, Penn.

MAJ. D. L. HOUGH, Construction Division, U. S. A., has received his discharge from the service and returned to his office at 17 West 42nd St., New York City. He has spent the greater part of the last seven years in Russia, returning to this country in October, 1917, when he applied for a commission in the Corps of Engineers. He served in the office of General Goethals in Washington until April, 1918, when he was commissioned with the rank of major in the Construction Division, and was later assigned to special duty at the port of embarkation, Hoboken, N. J., as Army representative on the Longshoremen's War Committee.

B. M. ATWOOD has resigned as state engineer of Arizona. It is understood that Mr. Atwood will enter the contracting business, specializing in highway construction.

CAPT. A. D. BUTLER, Corps of Engineers, U. S. A., returned recently to his duties as city engineer of Spokane, Wash. Captain Butler left Spokane in October, and was assigned to the construction of the Army warehouse at Schenectady, N. Y.

C. N. PERRY, assistant chief engineer of the Imperial Irrigation District, El Centro, Cal., has been appointed acting chief engineer and general manager, succeeding C. K. Clarke.

F. M. HAWTHORNE, assistant engineer, Pittsburgh, Cincinnati, Chicago & St. Louis Ry., with office in Terre Haute, Ind., is now assistant division engineer, Pennsylvania R.R., with headquarters in Pittsburgh.

F. L. DORE, chief draftsman, office of chief engineer, Wabash Ry., in St. Louis, is now, by recent appointment, assistant engineer, Pittsburgh & West Virginia Ry. at Pittsburgh.

L. C. HULBURD, whose appointment as division engineer, department of the State Engineer and Surveyor, of New York, at Rochester, was mentioned in these columns last week, has been connected with the state engineering department for the past 13 years. As resident engineer, he was in charge of the construction of the barge canal water-supply reservoir at Rome and several of the canal lock terminals. Previous to entering the state engineering department he was engaged on the St. Lawrence River hydraulic power development at Massena, N. Y., and the Chattachoochee River power developments near Atlanta, Ga.

A. R. DUNN, assistant engineer, Pittsburgh, Cincinnati, Chicago & St. Louis Ry., with office in Richmond, Ind., has been transferred to Terre Haute, succeeding F. M. Hawthorne, appointed assistant division engineer, Pennsylvania R.R., at Pittsburgh, as mentioned elsewhere.

MAJ. HENRY W. WILSON, Corps of Engineers, U. S. A., who received his discharge from the service recently, is now become associated with Young, Corley & Dolan, Inc., New York City. He served for 20 months with the 302nd Engineers, 77th Division, American Expeditionary Forces. Formerly he was representative of the sales department, Barber Asphalt Paving Co., New York City.

A. E. OWEN, chief engineer of the Central R.R. of New Jersey and the New York and Long Branch R.R., has been appointed also chief engineer of the Philadelphia & Reading R.R., the Atlantic City R.R., and the Port Reading R.R., succeeding S. T. Wagner, resigned. Mr. Owen was educated at Rutgers Scientific School, and joined the staff of the engineer of Essex County, New Jersey, in 1896. Two years later he became draftsman for the Central R.R. of New Jersey. He was successively transitman, assistant engineer, and assistant to the chief engineer. In July, 1916, he was appointed principal assistant engineer, and afterwards became chief engineer.

S. E. SHOUP, assistant engineer, Kansas City Southern Ry. at Kansas City, Mo., has been appointed engineering assistant to the general manager.

F. N. HOLMQUIST, consulting engineer, Phoenix, Ariz., has been appointed state engineer of Arizona, succeeding B. M. Atwood, resigned, as mentioned elsewhere. He was graduated from the University of Illinois in 1909, and has spent the greater portion of his time in Arizona. He was city engineer of Phoenix for several years previous to entering private practice in 1914.

CAPT. LAWRENCE D. STODDART, Construction Division, U. S. A., has returned to his duties as city engineer of Trinidad, Colo.

MORTIMER FREUND, who has been in charge of the trench warfare branch, loading section of the explosives and loading division, Ordnance Department, Washington, D. C., recently received his discharge from the service and resumed his work in the firm of Eadie, Freund & Campbell, consulting engineers, New York City.

REVOE C. BRIGGS, previously of the 472nd Engineers, has returned to his former position as assistant engineer, water resources branch, United States Geological Survey, at Pasadena, Cal., following his discharge from the service.

OBITUARY

BROOKS D. HABERMAN, assistant city engineer of Marion, Ohio, died in that city Jan. 4. Previous to his entering the city engineer's office four years ago he was associated with the Marion Steam Shovel Company.

JOHN W. HORTON, for several years assistant city engineer of Sacramento, Cal., died in that city Dec. 24. He was a graduate of the University of California, and was engineer in charge of construction of the Sacramento bypass weir, which was recently completed.

MARVIN W. KINGSLEY, superintendent and chief engineer, city water-works department of Cleveland, died recently at Ripley, N. Y. He was in the service of the water-works department from 1892 to 1901, and the lake intake tunnels were constructed under his supervision. He was born in 1846 and went to Cleveland in 1873.

WILLIAM APPLETON HAVEN, retired civil engineer of Buffalo, died in that city Jan. 6 at the age of eighty-seven. His early engineering experience was in railroad work on the Wisconsin Central and the Burlington. Later he engaged in railroad construction in Vermont and in the double-tracking of the New York Central. He went to Buffalo in 1877 in charge of construction work for the Erie, Lehigh Valley and Buffalo Creek Railroads. In 1885 and 1886 he was associated with Robert Harris in the building of the Northern Pacific Railroad, and later, the Montana Central. He returned to Buffalo in 1890 and became supervising engineer for the Erie Railroad, specializing in grade crossing work. He served in the Civil War as first lieutenant in a New Hampshire volunteer regiment and later became commissary general of a Montana organization. He became a member of the American Society of Civil Engineers in 1873.

DR. WALLACE C. SABINE, professor of mathematics and natural philosophy, Harvard University, and formerly dean of the Lawrence Scientific School of Harvard, died at his home in Boston Jan. 10. He was fifty-six years of age. He was graduated from Harvard with the degree of M. A. in 1888 and became a member of the faculty in the next year. He received the degree of doctor of science from Brown University in 1907 and the same degree from Harvard in 1914. He was a member of the National Academy of Sciences. A large part of his research work was made public in articles in *Engineering Record.*

WALTER V. TURNER, manager of the engineering department, Westinghouse Air-Brake Co., died in Pittsburgh Jan. 9. He was the inventor of the type "K" quick-action air-brake triple valve, which has been a controlling factor in making possible the operation of the long freight trains. He was the inventor of many other railroad appliances. He was born in England in 1866 and received his education at the Textile Technical School, Wakefield, coming to the United States in 1888. He received the Langstreth medal in 1911 and the Elliott Cresson medal in 1912.

Digging and Backfilling With One Machine

Development of the Usual Trencher in Which the Two Operations Are Nearly Simultaneous

A machine that digs and backfills in practically a simultaneous operation has recently been produced. It is a development of the usual trench machine, a dipper bucket having been added. It works in varying material between very loose earth—in which a bucket with shovelers would be necessary—and hardpan and rock, in which blasting is required.

As indicated in the accompanying illustration, it is, in effect, a movable shovel mounted on a separate car and

NEW DIPPER TRENCH MACHINE

operated by an engine placed in a stationary car ahead of the trench. A movable anchor is placed at the opposite end of the trench, and the dipper car is moved back and forth by the same lines that do the holding and digging. With an operating crew, of two men, under ordinary conditions, the earth, dug ahead by the dipper, is carried back and used immediately as backfill. If for any reason the dipper cannot be operated, it is locked up out of the way upon the car.

On a sewer job in Stratford, Conn., during December, this machine was operated on one-half ton of coal per day with but two men; one engineman and one shovelman. During December this machine, operating in soil varying from loose material to hardpan, dug approximately 1250 lin. ft. of trench 4 ft. wide and 11 ft. deep. The contractor stated that in clay he was able to make approximately 100 ft. a day; in coarse gravel and sand, approximately 80 ft. per day, but these figures were reduced to 30 or 40 ft. per day in hardpan. An advantage of this machine, pointed out by the engineers on the job, lies in the fact that it obviates the necessity of placing the excavated material along the edges of the trench, thus reducing the weight on the bank and effecting a saving in handling and sheetpiling in the kind of work to which the machine is best adapted. The machine is manufactured by the Moore Trench Machine Co., Rockaway, N. J.

Italian Government Commission Buys American Lumber

The purchase of 3,500,000 ft. of yellow pine and timber has been made by commissioners representing the Italian Government, according to a report received from the Southern Pine Association. The timber was specified as Southern pine, merchantable grades, for delivery at Gulf ports, to be moved to Italy by ships supplied by the purchaser. The order has been distributed among the Southern pine mills east and west of the Mississippi. The product will be inspected at the mills by the Association of Inspectors and shipped to designated ports to await the cargo steamers.

The association also states that reports are current that France and England will also buy lumber in this country through the various commissions that handled war-time purchases, and the association points out that if the purchasers supply the cargo space the problem of shortage of ships will be very nearly solved for this country.

National Slag Association Elects Officers

The National Slag Association elected officers for the year 1919, and appointed an executive committee, at a meeting held Jan. 10 in Cleveland. The three officers elected are F. A. Sarstedt, C. E. Ireland, and H. J. Love, elected respectively president, vice president and secretary-treasurer, and the executive committee consists of F. A. Sarstedt, L. A. Beeghley, L. H. Hawblitz, E. H. Kuttner and C. L. McKenzie. The executive committee was authorized to act as a contact or coöperation committee with similar committees appointed by the national organizations which are supported by the sand, gravel, and stone interests in the United States.

The report states that in all about 80% of the commercialized blast furnace slag tonnage of the country is represented by this association, whose aim is the ultimate standardization of this product when used as railroad ballast, concrete aggregate, or in macadam highway construction.

French Munitions Department Now Reconstruction Ministry

The Department of Industrial Reconstruction in France has been formed from the armament (munitions) department. M. Loucheur, who has been the minister of armament, will retain the directorship of the new department, according to a recent commerce report. The ministry, it states, will be responsible for the development of industrial production of all kinds, and will distribute among the industries the orders which shall be placed by other Government departments. It will also assist in the preparation of projects relating to the increase of national production, with the object of adapting the munitions factories, created by the French Government and private companies for national defense, to the industrial period now at hand.

Business Notes

The Independent Pneumatic Tool Co., Chicago, Ill., announces the opening of a branch office and service station at 1103 Citizens Building, Cleveland, Ohio.

The Lake Shore Shale Brick Co., Ashtabula, Ohio, has been merged with the Burton Townsend Co., Zanesville, Ohio, and the new company will be known as the Burton Townsend Co. The capital stock, it is said, will be $3,500,000.

P. E. Francis, who has in the past conducted a railroad and industrial equipment business under the name of and in conjunction with Edward Jobbins, has severed his connections with Mr. Jobbins, and his business in the future will be conducted under the name of P. E. Francis & Co., Marquette Building, Chicago, Ill.

The United States Cement Tile Co. is a recently organized corporation, with $100,000 capital. The officers are Matthew Gunton, president; E. F. Norris, secretary and treasury; G. R. Mueller, general manager; W. H. Ault, superintendent.

Trade Publications

Electric tractors and industrial trucks for use in freight houses, warehouses and manufacturing plants are the subject of four 6 x 9-in. bulletins of four and eight pages issued by the Buda Co., Chicago. The tractors have three wheels and are used exclusively to haul trailer trains. The trucks are designed to carry removable platforms which can be set on the floor for loading at any convenient place, and picking up later by the truck.

The Lidgerwood Manufacturing Co. has issued a 9 x 12-in. 32-page catalogue, bulletin of 1918, illustrating and describing its line of steam mine hoists.

A. S. Cameron Steam Pump Works, 11 Broadway, New York, have issued a 12-p. bulletin on pumps for marine service. This bulletin shows sectional and complete views, as well as description and tables, that will be of service to anyone interested in the subject of marine pumps.

The Hunting Davis Co. has issued a 6 x 7½-in. pamphlet illustrating various structures built by the company.

Sanitary Problems in Burma Solved by American Engineer

TACKLING the sanitary problems of a mining camp in an Indian jungle has recently fallen to the lot of a young American engineer. He tells his own story on p. 172. Mosquito control, water-supply, waste disposal, are some of the problems which he was called upon to solve under unusual conditions, which may fall to the lot of almost any enterprising American engineer in these days.

Irrigation Extension Needed in Russia

IRRIGATION opportunities in Russia, set forth by an experienced engineer on p. 191 of this issue, are large. When order and industry are once more restored in that great country, irrigation will demand a large share of attention. Enough has already been done to point the way, but as yet only a beginning has been made. Besides contributing to the food supply of its own country and the world, the extension of irrigation in Russia would supply needed cotton for Russian spindles —a fact of great economic importance to Russia.

Public Works As Memorial Structures

FROM several quarters comes the suggestion that important public-works engineering structures about to be built might be planned and dedicated as memorials to our soldier dead. It is a bold suggestion, for commonly the works of the architect are alone held to be suitable for memorial use, and age-long custom requires structures of purely monumental character, free from all element of service. Yet there is distinguished precedent for utilitarian structures—not merely memorial fountains, but even a memorial bridge. What structure, indeed, can more truly carry out the mission of holding constantly before the people's thought the spirit of memorial dedication than a great, enduring public work that enters into the daily life of ourselves and our children? Public service and public remembrance may well be joined; service will but grace the memorial and make its message more eloquent.

Research Work Results Should Not Be Scrapped

HEARTACHES have been caused by the abandonment of all sorts of war work without provision for preserving, much less completing, valuable data accumulated or being amassed through various kinds of research work. The heartaches will end, but the data will be forever lost. Can nothing be done to save and utilize this material? Might not much of it be turned over to permanent Government bureaus for completion, where that is needed, for digest and publication? Most Government agencies will prepare histories of their activities. In many cases, though, more is needed, for useful developments have been cut off just as they begin to give high promise. There is an obligation in such cases to the public which paid for the work, to see that it is passed over to some agency, private or public, so that the investment already made will be conserved.

Hammering Forms a Useful Development in Concrete

THE VIBRATION of the forms with an air or electric hammer during the placing of concrete is responsible to a considerable degree for the complete filling of the forms in the new Government concrete ships, and the consequent desirable density of the concrete. There is no reason why this development should not be extended to all kinds of structural concrete work, where somewhat similar form and reinforcement conditions prevail. The tendency to use a dangerously wet mix is due mostly to the desire to insure a concrete which will run around all steel and into the uttermost corners of the form. In the ship concreting it has been found that the constant hammering on the form when concrete is being poured sets up a vibration which with certainty fills the forms and possibly gives a denser mix. Well directed hammering serves every end formerly achieved by slicing or tamping, and in addition leads concrete by no means wet around bends and angles in forms in a manner not possible by any other method. Building and bridge contractors would do well to look into the possibilities of the mechanical hammer for their work. Skill is required in its use. The vibration of concrete already beginning to set is dangerous, and there is the possibility, in joining new concrete to that already some hours old, of pushing out the form and permitting an over-run down the face. But knowledge of such things come with practice. The use of the hammer is undoubtedly a valuable byproduct of our concrete-ship experience.

A Suggested Use of the Army Bases

FREE ports are recommended by the report of the Tariff Commission noted on p. 206. Leaving aside the question of the economic or political desirability of such an innovation, it so happens that physically we are better prepared to attempt the experiment now than we ever were before. At six of our large coast cities—Boston, New York, Newark, Philadelphia, Charleston and New Orleans—the Army is just completing large

port terminals with warehouse and wharf equipment. of a size and coördination unprecedented in this or any other country. Except for an unforeseen calamity, the reason for these immense units will have ceased to exist within the year, and the problem of their utilization will be added to the other burdens of the Government. What better layouts could be found for a free zone or port? Each terminal is Government property, on deep water, readily subjected to that physical control necessary to the free-port idea. Each one is provided with the necessary wharves to and from which material can be handled to ships, and the connected warehouses easily converted into the factories which are a part of a free port. Finally, they have the railroad connections over which may be brought in such domestic products as are needed to complete the manufactured article for re-export. Free zones must necessarily be subject to test before extensive adoption. The experiment may be made most cheaply in one of the new Army bases.

Time Spent in Port Increases Shipping Costs

"I DO not know whether we can build ships as cheaply as they can in Europe, but I do know that if we try we can handle freight more cheaply, and on the proper development of this handling hangs the success or failure of the American merchant marine." Thus spoke Secretary of Commerce Redfield at a meeting of handling-machinery men last week. His words are apt to suffer the neglect common to the obvious, but they are no less forceful for that. Current concern over the future of our merchant marine revolves around the cost of shipbuilding and the wages of seamen, in neither of which is it probable that America can—or, being able, wants to—compete with Europe, with its low-priced labor. But in handling the freight to and from the ship we have a problem peculiarly fitted to our national genius. If American ships are so designed, equipped and operated as to require a turn-around in port half that of foreign vessels, we can laugh at their savings in overhead, for it is not the cost of operating a ship that makes freight rates; it is the cost of its idleness. So, to reduce the time in port requires much more than mere mechanical fitting of wharf and ship. It means a fresh view of the whole transportation problem, a revised design and operation—from the sources of material up to the hold layout of the ship itself—and an education of the men to the advantages they will gain from the rapid turn-around. That engineers in hitherto unthought-of numbers are working on this complex problem indicates a new attitude of mind, which can but result in a successful solution, provided legislators and lay executives have the courage to break the new paths that will be laid out for them.

New Blood in the Shipyards

IN NO one other point is the development of our newly created industry of shipbuilding during the past year of stress more significant with respect to future growth than in the influx of new men into the shipyards. Managers and workmen have been recruited from other walks of life. From the ranks of civil engineering and construction came what we believe to be the most important contribution. But all serve to strengthen the yard spirit; it is the new men that are taking hold best in the shipbuilding work, a yard manager tells us. His explanation is that old-time shipbuilders are one-boat men; their minds are not sufficiently open to the requirements of a new era in the art. It is the prime value of the influx of new hands and brains and ways of thinking that precedent, the mere following of tradition, will have less sway over our shipyard work in the coming development. Though the serious man-power shortage in the shipyards which prevailed and still continues makes a present survey of conditions less definite than could be desired, yet the conclusion is clearly justified that the new men, the new supply of energy, will carry the shipbuilding industry forward to new accomplishments.

Delayed Transit Planning and Growing Problems

RESUMPTION of municipal development after the interruption due to the war finds the problems of transit improvement presenting a changed aspect. While planning was halted and set back, city populations continued to grow, and transit needs became more urgent because of the resulting increase of congestion. The problems put to the engineer have thus been made more immediate, affording less time for study and analysis. They call for earliest possible resumption of transit planning.

Before the war, rapid-transit projects had reached an active stage of development in such cities as Detroit, Cincinnati, Pittsburgh and Cleveland. In a number of others, however, traffic conditions were approaching that point where remedial action must be initiated. These problems of transit shortage still exist, each one having been made measurably more difficult by the lapse of two years. But shortage is not the only factor in the transit situation today, for the conditions that have developed in the street-railway industry present fresh problems to the city and to the engineer. Cities that have heretofore studied rapid transit alone may need to review their work with regard to coördinating surface and rapid-transit transportation. Others, which have not yet outgrown the range of surface carriage, confront new opportunities and new obligations in study of the relations between city development and transit plan.

It is certain, then, that transit study is today a subject of broader scope than before the war, and that it affects the nation's city populations in quite remarkable degree. Moreover, its problems are now exceptionally urgent, and must be accorded a high degree of priority in the scheduling of public works. Further delay in planning is certain to accentuate the seriousness of each problem concerned.

Rapidly increased outward expansion of cities may be expected in the immediate future. During the war the stagnation of building operations hemmed in territorial growth, so that a nation-wide housing shortage developed. There is sure to be a reaction from this restraint. It will mean abnormal spread of the populated areas of cities and, in turn, greater transit needs. With this prospect, we may see even more clearly the imperative need for setting about the study of transit matters at the earliest possible moment.

Progress in Engineering Society Organization in 1918

THERE has been developing for years a healthy dissatisfaction with the organization of engineering societies. The older men have long declared that the engineer should be an influential member of the community; witness, for example, the repeated statement of this view in presidential addresses before the American Society of Civil Engineers. But the older men have been content with statement only. They and the leading engineering societies have apparently lacked the incentive to crystallize their statements into a program and to create machinery for the realization of that which they had so well expressed.

The younger men, however, were not content with high-sounding declarations on state occasions. They expected service from their engineering societies, and, in addition, flexibility and virility. They voiced their impatience, and as a result virile local societies appeared in various sections of the country.

Until the year 1918, however, there was no evidence that the recognized leaders of the profession took seriously the dissatisfaction or were openminded on the proposals for remedying the conditions against which there was complaint. With this year came a change. The fresh thinking stimulated by the war, but even more the constant pounding of those who demanded a new vision, has stirred the conservatives to action, so that even in New York, the rallying ground of the standpatters in engineering society organization, one daily meets former conservatives who advocate more active society organizations. Some few particularly honest ones even state that they have had a change of heart, though most of them try to forget their former league with inaction. The tangible evidence of the new spirit is the very hopeful view generally taken of the prospect for results from the Committee on Development of the American Society of Civil Engineers.

The change in attitude in the conservative East does not mean, of course, that the battle for virility in society work is won. New plans will require new machinery, new machinery will require new men. The victory proceeds so far only to the undertaking of the plans. There must be discussion and agitation, that this planning be well done. Then, when the planning is properly completed there will be needed more agitation and more pressure, that the machinery may be adequate and the men in charge in full sympathy with the plans.

While the ultimate form and aims of engineering society organization cannot be predicted in detail, there has been enough crystallization to show unmistakably the main character of the results. Possibly the most striking bit of evidence of the new aims is afforded by the resolution of the civil engineers' development committee—a resolution, we take it, intended to set the course for the committee's work. It was the sense of the committee, so the resolution declared, that the American Society of Civil Engineers "should adopt the principle of becoming an active national force in economic, industrial and civic affairs." The committee further recommended that the engineering profession establish offices in Washington "charged with the duty of keeping fully advised as to all matters in which the engineering profession should have a voice." Since the resolution was passed the Engineering Council has decided to open an office for just that purpose in Washington.

We are, then, safe in assuming that the engineering society organization of the future will take full account of the engineer's civic obligations. The selfish purpose, voiced now in constitutions of the national engineering societies, has given way to enlightenment.

As to form of organization, we can predict with certainty that it will be democratic. Autocracy in engineering society management is disappearing as surely as the dynasties of Middle Europe, and with its disappearance will go that inflexibility, that indifference to the needs of the individual engineer which has cursed the larger societies and driven many prospective members from them. In this connection we cannot refrain from quoting from an editorial on the American Society of Civil Engineers in *Engineering Record* of Jan. 16, 1915, four years ago.

"Present tendencies in every field" said the editorial, "are toward democratization. The cry against autocrats was louder than the first rumble of the European war. The wise corporation official has changed his motto to read, 'The public be pleased.' Industry's tyranny over the individual has been broken by workmen's compensation acts. Coöperation, fellowship, representative rule, are succeeding the cruder forms that preceded.

"The movement in the American Society of Civil Engineers is of the same order. In a small way it mirrors the large swing of world events and race tendencies. Its ultimate results none can doubt. It behooves those who have placed the society on its present eminence, and have made it financially impregnable, to take hold in the new spirit, that the society may broaden and grow, grasping the larger opportunities which a more complex age is placing before it."

The quotation is indicative of the signs long ago apparent to those who would see.

One further result seems to be foreshadowed, though the signs are still too nebulous to predict either the time or the detailed nature of the result—the heading up of all societies in one widespread clearing house, so that unified professional action may be secured. The Engineering Council, hampered by its form of organization, is nevertheless making headway. The civil engineers' development committee is keeping in touch with similar bodies in other societies, while a number of plans for centralization have come from various sources. All indicate the widespread determination that there shall stand before the public one engineering profession, and not isolated local organizations or bodies of civil, of mechanical and of other specialized engineers.

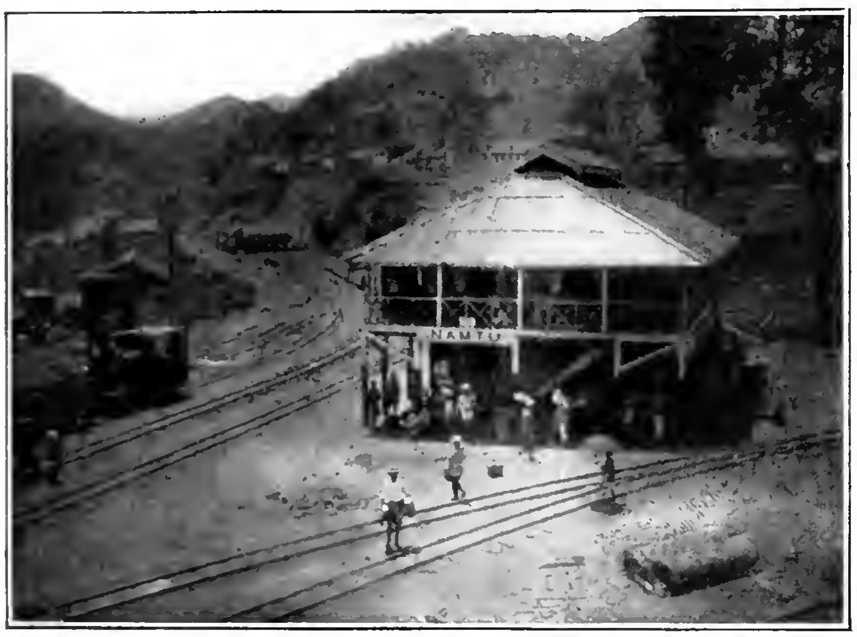
Viewing engineering society organization broadly, then, one can feel satisfied with the year 1918. There has been greater progress—or at least greater visible progress—than in any other year in the memory of living generations. What has developed is but a start, it is true, but a most encouraging one. There is as yet but little result, and since there are still many standpatters and much inertia there can be no relaxing by those with high vision and purpose. The skirmish only is over; the full victory is far from won.

Sanitary Engineers Get Direct Results In East Indian Mining Camp

Experience at Namtu Is Typical of Tropical Sanitation In Rural India—Jungle Cleaning and Drainage Are Successful Measures in Mosquito Suppression—Local Conditions and Habits

By Harry N. Jenks
Sanitary Engineer, Burma Mines, Limited, Namtu, Burma

MOSQUITO control and camp sanitation through the works and follow-up operations of the engineer are effectively preserving the health of Europeans and natives in the jungles of India. Intensive clearing and drainage—utilizing cheap labor rather than oiling on account of the expense of the latter—are the principal methods used by the Burma Mines, Ltd., at the frontier town of Namtu, in the Northern Shan States, Burma. Camp sanitation problems also include water-supply, sewage and refusal disposal (conservancy) and general sanitation. The camp is on the Namtu River, 550 miles from Rangoon, in a region of irregular topography varying from 1755 to 2100 ft. above sea level. Until 1911, when the smelter was moved from Mandalay to Namtu, nothing was done in the way of sanitation beyond the barest necessities. However, with the establishment of the smelting works and refinery, together with the accessory plant and shops, this village was made the center of the company's activities, and the attendant rapid growth of the camp made it necessary to provide a satisfactory water-supply and adopt a system of conservancy. A few house and street sweepers were employed to care for the bungalows and compounds, while a small force was engaged in removing and burying in trenches the night soil from the camp. By this time also the jungle had been cleared of the larger trees, for use as timber and firewood, thus affording relief from the previous almost nightly maraudings of tigers and cheetahs, diminishing greatly the danger from snakes, and making it decidedly more convenient to get from one part of camp to another.



THE RAILWAY STATION COMMANDS A VIEW DOWN THE NAMTU RIVER VALLEY

By 1913 Namtu had grown to be the most important mining camp in the country. Native labor from distant provinces and from China began to appear in great numbers, and, next to Rangoon and Mandalay, Namtu contained the largest group of European residents in Burma. Realizing the importance of greater sanitary vigilance, in view of the increasing population, the company established a sanitary department to work in coöperation with the medical department, in guarding the health of the community.

The personnel of the medical and sanitary staff consists of one European sanitary engineer, two Indian sanitary inspectors, six compounders and dressers, two overseers, one sanitary sweeper, 30 hospital sweepers, eight conservancy sweepers and 20 coolies on jungle cutting and drainage.

Sanitary conditions in this mining camp may be taken as typical of the rural or jungle districts. In general the fight in the Indian municipality is mainly against plague, cholera and smallpox, while in the jungle one is face to face with malaria. By the individual sufferer plague and cholera are more to be dreaded than malaria, but it is questionable whether there is any other single disease in the tropics that causes a greater sum total of misery and human waste than malaria and malarial cachexia. In this respect, malaria is to the resident in the tropics what colds and grippe are to those in America, especially in the New England states. In spite of the drainage afforded by the steep slopes of the hillsides of this region, the inevitable small collection of water in paddy fields and along the banks of the more sluggish streams have always furnished breeding places for mosquitoes. Even in the hills malaria may abound, because the rank growth of jungle impedes the surface run-off and thus allows mosquitoes to breed in every available hollow, as well as in the accumulations of water found in the stalks and among the leaves of the undergrowth. Many coolies coming from the jungle stations along the railway act as malaria carriers, so that in interpreting our malaria statistics a careful distinction must be made between local and imported cases.

Water for the European side of camp is derived from springs in a swampy area. It is collected in open ditches leading to an earth-lined reservoir 30 ft. square, in which it is impounded to a depth of 8 ft. by a concrete dam. The water is carried down the hillside in a 4-in. pipe, passing through two pressure-break reservoirs on the way, and is then distributed throughout the camp by pipes of various sizes. The source of supply is protected naturally by its remoteness from human habitations and by its position near the top of the slope. In this connection it should be noted that typhoid fever is practically unknown in this region.

For conservancy purposes the latrine-trenching method of the disposal of excreta has been adopted. Sanitary practice in India has in general favored the

latrine in its various modifications as a solution of this problem. In justice to a system which in America has been practically abandoned in favor of the water-carriage system, it must be admitted that here in India it serves its purpose surprisingly well. The people are disposed to use the latrines, and a plentiful supply of labor is at hand to attend to them. In Namtu the wet-pail system is used, the night-soil being removed twice daily by bullock carts to the trenching grounds a mile away from camp, and there buried.

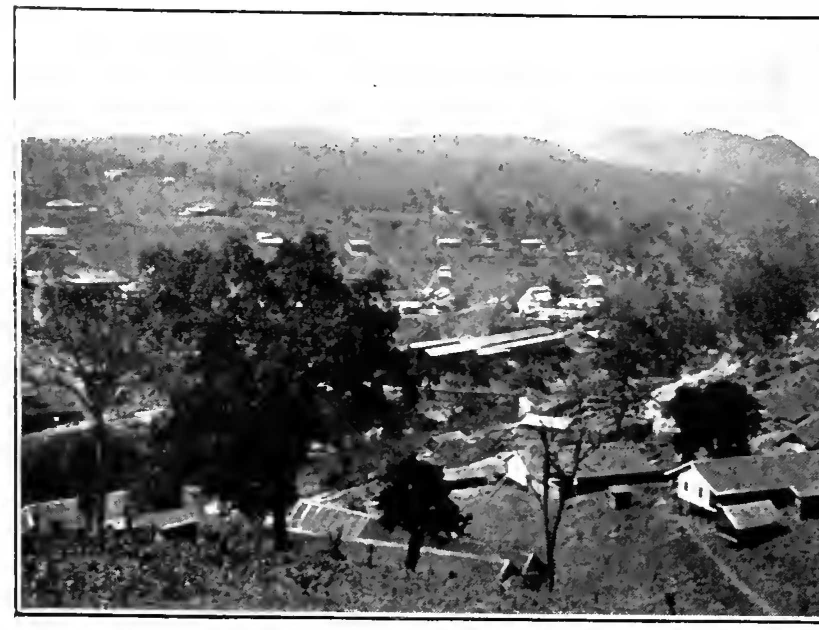
On the smelter side, owing to the absence of cart roads, the pails must be carried to the trenches near at hand, though far enough away to avoid local nuisance. In order to obviate further expense in this respect, sanitary privies are now being built instead of pail latrines. In the bungalows themselves, the use of commodes, which are emptied and cleaned twice a day by the house-sweeper, is found to be entirely satisfactory both from a sanitary and sightly standpoint.

Of many limitations to the applicability of the latrine-trenching system to the problem of conservancy, one of the most obvious is that it does not provide for the disposal of waste water from house baths and kitchen sinks. In Namtu this waste water is discharged onto the ground and flows away from the house through small ditches running down the hillside. This involves expense and trouble in keeping the water from collecting in small depressions under the houses and thereby allowing mosquitoes abundant opportunity to breed on the premises. To overcome at one stroke the disadvantages of the existing method, the sanitary department has prepared a design for a comprehensive water-carriage sewerage system to serve 60 bungalows on the European side of camp, with a new European hospital now being completed.

THESE COOLIES CLEAR JUNGLE AT $1.50 PER ACRE

The sanitary department maintains a squad of street-sweepers in the neighboring village of Pang Hai to coöperate with the local authorities in keeping the town clean. This is an important consideration in view of the fact that about a third of the 3000 coolies employed by the company live in Pang Hai and Ih Aung villages.

Prevalence of malaria throughout the region is the greatest detriment to health in Namtu. The extent to which it contributes to sickness among the company's workmen and staff is shown in the next column.



ROUGH TOPOGRAPHY IS FAVORABLE FOR DRAINAGE

In 1916 the total number of cases among the Europeans and Anglo-Indians decreased by 39% as compared with 1915. It was in 1916 that jungle clearing and drainage work was maintained with a thoroughness not attempted theretofore. The returns for the first ten months of 1917 indicated that the total number of malarial cases for that year would be about 50% that of 1915. The increase in the number of Asiatic cases noted in the table is only apparent, and is due to the greater number of imported cases and patients who avail themselves of treatment at the company's hospital.

ANALYSIS OF MALARIA INCIDENCE, BASED UPON NAMTU HOSPITAL RECORDS

Number of Cases	1915 Europeans and Anglo-Indians	1915 Asiatics	1916 Europeans and Anglo-Indians	1916 Asiatics
Malaria	238	4,589	145	5,533
All causes	706	12,243	828	13,236
Ratio malaria to all causes	0.34	0.38	0.18	0.42

In the jungle itself the bamboo is regarded as the plant most responsible for the breeding of mosquito larvæ. Especially is this the case when the bamboos are cut, thus leaving a cup in each shoot in which the larvæ thrive. After the bamboos and larger jungle growth have been removed, the weeds and grass that spring up favor the development of larvæ by arresting the surface run-off of rain water. It seems probable that in Namtu the incubation period of the mosquito egg may, under favorable conditions, be as short as one day. In order that no small collection of water shall remain for more than a day after a rain, the grass on the hillsides throughout the camp is kept as low as possible, so that the surface drainage and evaporation may be materially hastened.

Prior to 1917 jungle-cutting was done by a gang of about 12 coolies by day labor. This was found to be unsatisfactory as regards both expense and quantity of work done, so that during 1917 the work was let out on contract, with a great improvement in rapidity and thoroughness. The tool with which the cutting is done is known in Burma as the dah, and is similar to the Cuban machête. The dahs vary in weight and form according to the character of the brush to be cut. For the grass-cutting work we use the Kachin pattern, which is long and light. The ground is too uneven for the use of scythes, but short sickles are em-

ployed to advantage on the tough wire grass that grows near the streams.

The usual method of oiling mosquito-breeding collections of water finds little application in Namtu. Aside from the almost prohibitive expense, there are no ponds of importance that do not receive a thorough flushing with every tropical rainstorm, so that in any case the oil would be promptly washed away.

Open ditches drain the few low-lying places, but these require constant cleaning to keep them free from a rank growth of weeds. It is proposed eventually to underdrain the swampy areas by the use of open jointed tile. The drawback to this is the expense, since in Burma all drain tile and sewer pipe is made on the potter's wheel.

Quinine prophylaxsis is not generally practiced here. It seems to be the opinion among the company's staff that the possible injurious physiological effects of the drug when taken in the doses required to secure more or less complete immunity are more to be feared than the chances of getting malaria. The recommended dosage is 5 grains every other day during the monsoon season, or from the end of May to November. It is given in the sulphate form, in solution acidulated with citric acid. At the hospital quinine is dispensed in pill form to the natives.

IMPORTED COOLIES BRING IN MALARIA

In this remote corner of Asia the cost of supplies and materials of construction is comparatively high even in normal times, but now, due to war conditions, everything that must be imported has risen excessively in price, and many materials can scarcely be obtained at any price.

The following are now (November, 1917) a few typical prices of materials in Namtu: Sawn timber, $8 per ton of 50 cu.ft.; common red brick, $5.12 per 1000; portland cement, $6.40 per barrel of 3.8 cu.ft.; sand, $1.76 per 100 cu.ft.; stone, $1.60 per 100 cubic feet.

Such materials as earth, sand or stone are measured in cubic feet rather than cubic yards, because the former unit is more readily appreciated by the native contractors.

A recent quotation on sewer-pipe from Mandalay, the center of the ceramic industry, was 6, 10 and 12 cents per lineal foot for 4, 6 and 8-in. pipe respectively.

Wages paid coolies in the Orient are proverbially low, so likewise is the efficiency of the workmen. In India proper, coolies get from 4 to 6c. per day, but in Burma the wage scale is considerably higher. In Namtu the scale of daily wages for unskilled labor is as follows: Railway and maintenance-of-way, 20c.; all other work of a general nature, 24c.; work in the smelter, 32c. The average for such skilled labor as carpenters, pipe-fitters, masons, etc., is 80c. In terms of a day's work the above figures for unskilled labor correspond very closely with wages of $1.50 to $2 per day.

Recognizing the inferiority of day labor in India, it is the general custom here to have even the smallest piece of work done by contract. It is no uncommon thing to let a contract for a five-rupee ($1.60) job.

In Namtu contractors flourish because of the great amount of construction work that is being carried on throughout the year. The big jobs are handled almost exclusively by Chinese contractors, since the greatest proportion of construction is in timber, and all the carpenters are Chinese. Masonry work, which is next in importance, is given to Indians and Burmans, who have a monopoly in that trade. Much petty contract work is done by Burmese contractors, and very often some native foreman, or "coolie gong," will start in this business on his own account in order to make money without having to do any work himself, this being the height of his ambition.

Under average conditions, the cost of getting various kinds of work done by contract, inclusive of labor and supplies, is as follows:

Class of Work	Rate
Concrete and masonry	$32.00 per 100 cu.ft.
Brickwork	25.60 per 100 cu.ft.
Timber work	32.00 per ton of 50 cu.ft.
Excavation:	
Earth	0.24 per 100 cu.ft.
Loose rock	0.80 per 100 cu.ft.
Hard rock	1.60 per 100 cu.ft.

All new construction work undertaken by the sanitary department and nearly all of the jungle clearing work are now being done by contract, the latter being the largest single item in the operating expenses of the department. During the rainy season (May to November) it is necessary to go over the camp once every two months. Each cutting amounts to 160 acres on the European side of the camp. Under average conditions, the contractor will make a fair profit at $1.44 per acre. On a contract recently let to a Chinese 140 acres was cleared in 36 days, the average rate being 0.27 acre per coolie per day. On a previous contract undertaken by coolies from Orissa Province, India, 70 acres of jungle grass were cleared at the daily rate of 0.24 acre per coolie, but far more supervision was required than with the Chinese labor.

Those persons in America whose acquaintance with India has been gleaned from the fiction of poets and writers, who have sung the praises of India's mysterious charms, from the lovely vale of Kashmir to the golden Irawadi shore, will, if they chance to come to this country, feel under the necessity of applying a large correction factor to the sum total. The sanitarian is confronted with the problem of making what he *can* do measure up reasonably well to what he sees on every hand *ought* to be done. Since sanitary and public health work is essentially a personal problem, the habits and customs of the people whom such work is to benefit are the chief factors with which the worker has to concern himself.

It is axiomatic in the East that the native "workman" never does as much as he is paid to do. He is generally a living example of that otherwise highly useful theory in structural design known as "least work." To get more work out of him requires as much, if not more, energy from the outside in the form of active supervision than is obtained from him in return. Climate undoubtedly has been the most potent factor in arresting the development of the capacity for work on the part of the indigenous population. Namtu is more fortunate than many other places in India in possessing a climate that is about midway between temperate and tropical, although during the summer months the combination of 80° temperature, 80% relative humidity and 60 in. of rainfall approaches sufficiently close to tropical conditions.

Perhaps the most important of all the influences that govern the character and effect of the work done among the natives of India is the influence of habit. Habit is practically the sole arbiter in the lives of the entire population, in all that they do and will not do; and this ingrained force of habit attains its most far-reaching development in the caste system. This fact furnishes many novel problems to the sanitarian. The effect of the sanitarian's work upon the people of India is at one and the same time his chief reason for enthusiasm and despair. Considering the almost limitless field for his efforts and the beneficial results that appear when insanitary conditions are relieved ever so slightly, he is bound to be enthusiastic. On the other hand it appears at times an almost hopeless undertaking to attempt to make any real progress, in view of the magnitude and the difficulties of the task which confronts him.

Formation of Technical Sections Is Suggested

President A. N. Talbot in Annual Address Before American Society Advocates Changes in Present Machinery of Organization

REVIEWING the society's activities, already announced, during the past year, including the work of the Engineering Council (see *Engineering News-Record* of Jan. 9, p. 81), the retiring president of the American Society of Civil Engineers, Arthur N. Talbot, proposed several fruitful lines of development for the society, at the annual meeting on Jan. 15. The following abstracts from his address include the suggestions for more technical committees, for technical sections and for greater participation in public affairs.

The discussion of the purposes and functions of an engineering society, such as the American Society of Civil Engineers, should not be restricted to the purposes given in the constitution, which may merely follow precedent or may be worded to conform to a state statute governing the charter of the society. Some of the functions of the society, may it not be agreed, would include at least the following:

A collector and disseminator of engineering knowledge; a forum for the discussion of engineering questions; a stimulator of research and of the progress of engineering science; a developer of engineering methods and practice; an active force within and without professional circles; a creator of engineering policies and an originator and patron of constructive and progressive movements in engineering; a means of mutual helpfulness and coöperation; an instrument for advancing both professional interest and public welfare, and an agency for discussing the various phases of public problems and for participating in the service which all thinking organizations should give to society.

Technical Papers Not Sufficient

The technical activities of an engineering society are of prime importance—meaning by technical matters not merely mathematical methods and routine work of engineering, but all relations to the science and art of engineering in and out of professional circles, and also the technical relations with the public. One method of carrying on this technical activity has been the presentation and discussion of papers on engineering topics.

But is the society doing all it should in this direction? Is there not need for papers in fields not often taken up? Should there not be more short, terse papers, devoid of details, which should stimulate and set engineers to thinking? Would it not be possible and desirable to have more papers dealing with principles, with the advances of engineering, with new methods and requirements? May it not be worth considering whether to continue the policy of limiting ourselves only to those papers which are offered to the society, regardless of whether this policy leads to ignoring large fields and results in transferring to other societies the activities in these lines? Are there not opportunities for dissemination of knowledge like reviews of engineering construction and methods and digests of important engineering literature, which seem now not to have adequate expression through other agencies?

More Technical Committees Needed

Technical committees form one of the most effective means of carrying on the technical activities of an engineering society. They can coördinate and unify practice, develop methods, formulate principles and standards, and recommend improvements and advances in the art. Their influence can reach out far beyond the bounds of the society. For example, the American Railway Engineering Association has 23 technical committees, with a combined membership of 480, out of a total membership of 1100 in that society; the American Society for Testing Materials has 38 technical committees and 144 subcommittees, with a combined membership of 1094.

At the risk of seeming disloyal, the opinion may be advanced that in influence upon engineering practice, in effect in the industries, in influence upon relations of engineering business, in advancement of engineering knowledge and the methods of manufacture and construction, and in influence in the outside business world, the achievements of these two specialized societies in the past few years have been such as to make some of the national engineering societies look to their laurels for leadership. The Committee on Development will find the need and opportunity for technical committee work an important subject for study.

An opportunity for energized activities lies in the formation of specialized divisions or sections of the society, to give attention to special fields of work, such as railway engineering, structural engineering and hydraulic engineering. Members would enroll in sections in which they are interested. Sessions and convention would be held to discuss matters of common interest, and each division might affiliate in some way with the work of other societies—the American Railway Engineering Association, the American Society for Testing Materials, the American Public Health Association, for example.

Any attempt at organization of the profession throughout the country for all the national societies should involve joining forces with local societies in every possible way. In every center of engineering the local engineering society should be the basis of organization. Some plan should be devised, perhaps by increase of dues, to contribute revenue from the treasury of the national societies to the chapters for use in this union work with the local societies.

For certain purposes it may be found desirable also to have a regional organization covering territory corresponding to the geographical districts now used in the selection of the nominating committee, for handling matters of common interest in a given region.

The provision for a New York Meetings Committee to take charge of the second meeting of each month, made by the Board of Direction on the recommendation of the secretary, is a step in advance. It would seem to the president that in any new plan for local associations or regional organizations, the resident membership in New York should be granted some degree of autonomy by the formation of a local association or chapter, and that the New York membership should be set at work and stirred up to realize and utilize the opportunities and facilities at their door.

Relations With Other Societies

The four Founder societies have many activities in common. The Engineering Council may soon have its membership increased by three more societies. The Engineering Standards Committee will have the coöperation of a number of societies besides the four Founder societies. It is increasingly apparent that engineering is a single profession; the various branches ramify and merge into each other in numerous ways. Many engineers think there should be one large, inclusive society to take the place of the several national societies—to be made up of the 35,000 engineers in the four Founder societies or the 100,000 or 200,000 who may claim the right to be classed as engineers. The further union of national societies and their coöperation with the local societies in developing engineering society activity are potential factors for the future and a fruitful field for the Committee on Development.

The engineer and the engineering society now have opportunity and responsibility in the direction of public duty far beyond what they have hitherto considered as their share. This is especially true at the present time, when the successful solution of so many public problems lies within the province of the engineer. The consideration of quasi-public matters has not always been accepted as a proper field for society activity. As an illustration, the opposition to the creation of the Committee on Valuation of Public Utilities may be recalled. Fortunately, the advocates of the appointment of the committee prevailed, and a magnificent report and discussion were given to the public. Besides, the activities of the committee stimulated thought and provoked discussion throughout our membership as few subjects have done.

It would be premature to try to outline methods for accomplishing the great work in public matters which should be undertaken, or the form of organization which is needed. The formation of a large and representative Public Affairs Committee has been suggested, and also a delegate convention organized to discuss matters of public interest and intended as a forum for voicing the sentiments of the organization. Whatever is done must give opportunity for exercising initiative and providing powers for action. Leaders must then energize the machinery provided.

Use of Available Funds

The activities here referred to will require adequate funds; it takes money to do things in this world. If the activities of the society are to be extended funds must be provided, and part may well be taken from the annual balance of $20,000 or $30,000 which in normal years may be left after paying the expenses of present activities. It seems reasonable that a society which has become established financially should not continue to put aside from annual receipts very large sums as endowment; the increase in endowment may be expected to come from other sources. Increase in membership will bring increased revenue, and many believe there should be a considerable increase in membership.

If it is agreed that there are activities which the society should undertake for the benefit of the profession and society, activities that will bring results and that will help in making the society a force of greater and greater influence, who will doubt that resources will be found to finance the work?

To shun the visionary, impracticable schemes, and yet not be too complacent about past accomplishment; to seek to be national and not provincial; to try to be both democratic and efficient; to lead in the progress of the times, and yet hold to the old and proven good; to work to be a powerful engine in technical affairs and a vital force in the life of the profession; to learn how best to give service to the community and the nation; to provide methods by which the profession may lead in progressive movements—these are ideals worth striving for in making a plan.

It should be borne in mind, too, that elaborate or complicated organization is likely to be ineffective; the machinery is not self-propelling. Mere paper proposals will not suffice. Whatever is done we must keep down on earth, accept only workable plans, but still not be content with stagnation or mediocrity. A plan may be worked out befitting the needs of a great profession. With such a great opportunity before it I confidently expect the Committee on Development will evolve a plan satisfactory to the society, and that a stronger, more useful, more virile society will result. I confidently look forward to a great future for the American Society of Civil Engineers.

Defends Construction Division's Form of Contract

General Marshall Urges Engineers To Educate Those Who Would Not Permit It—Advocates League of Technical Societies

WIDESPREAD opposition to the well known Construction Division sliding-scale cost-plus form of contract is not based on a knowledge of its operation or advantages, said Gen. R. C. Marshall, Jr., head of the Construction Division of the Army, in an address before the annual meeting of the American Society of Civil Engineers Jan. 15. General Marshall also advocated an amalgamation of all engineering societies, at least to such an extent as to permit the dealing by the Government with a unit body of engineers. Parts of the address follow:

Popularly, the form of contract which the Construction Division has used is almost universally known as a "cost-plus contract," but this term is not, strictly speaking, exact. The contract which has been used from the beginning, with slight modifications in nonessential details, has been one in which the contractor was reimbursed the actual expenditures with a fee to him graduated on a sliding scale. The percentage he receives gets lower as the cost increases, and a maximum figure is set which his fee can, in no case, exceed, no matter what the cost of the work may be. Many reasons dictated the adoption of this form of contract, which, to all who understand the facts, has proved its usefulness and its value beyond the peradventure of a doubt.

Why the Contract Form Was Devised

Take for a moment's consideration the conditions under which the original camps were built. The Cantonment Division (which later was enlarged and developed into the present Construction Division) was told that in 90 days it must complete the following work: It must have quarters ready for the training of over 1,000,000 men; it must go upon 32 virgin sites and upon each one build a camp, equipped in all essential details, to house and accommodate a draft army about to be called to the colors. It must draw, coördinate and complete the plans, prepare specifications and contracts, select the contractors, organize field forces for them, appoint constructing quartermasters, supervising engineers, and attending organizations. It must see that material in immense quantities was forthcoming; it must foresee and solve the engineering problems involved, and it must build 16 cantonments, roughly estimated to cost $6,000,000 each, to house 40,000 persons each, and 16 tent camps at about half the cost of the cantonments, but to accommodate almost as many men. Rough building was not sufficient--roads must be laid out, water-supply and sewage problems developed and overcome, and the result must be, so far as public utilities are concerned, comparable, at least in efficient working ability, with those of a city of the same size; and all this in 90 days.

Could any other contract known to man, or which the ingenuity of man could devise, have taken care of this situation? The making of plans, the advising of engineering features, the procurement of material, the formation of the organization, and the building itself, had all to go hand in hand. The markets for material and labor were in a period of instability to an extraordinary degree, and no contractor on earth could have made an intelligent bid upon any one of these projects had he had plans and specifications upon which to base it. Nor, conversely, could plans and specifications have been furnished him had he been in a position to bid. Let me not be misunderstood—the sole justification for the cost-plus contract as used during the war is not the uncertain and unstable condition brought about by the war, for the cost-plus contract, properly administered, is the proper, conservative and just method of doing contracting work—just alike to the owner, the engineer and the contractor.

In this connection, I want to draw the attention of this audience to the trend of Congress in this matter, as indicated in two provisions of law. In the bill making appropriations for the support of the Army for the fiscal year ending June 30, 1919, Public No. 193, 65th Congress, the following appears:

> "Provided, That where practical so to do, no work be done or contract made under or by authority of any provision of this act on or under a percentage or cost-plus percentage basis, nor shall any contract, where circumstances so permit, be let involving more than $1000 until at least three responsible competing contractors shall have been notified and considered in connection with such contract and all contracts to be awarded to the lowest responsible bidder, the Government reserving the right to reject any and all bids."

Also an act to authorize the President to provide housing for war needs, Public No. 149, 65th Congress, Section 7, has similar provisions.

I cannot believe that this tendency of Congress has been brought about through any effort by this society, or any similar to it. I am convinced that the best thoughts are quite to the contrary. I do believe that these laws, and the similar talk in Congress, are brought about by the lack of effort on the part of this society and similar ones.

Attack on Emergency Contract

Education is, of course, the only remedy worthy the name for ignorance or for mistaken apprehension of facts. Through ignorance and through mistaken apprehension of the facts of the case, the emergency contract outlined above has been the subject of bitter attack from persons in and out of the Government service and from quarters high and low. Let me add that these attacks have, in my opinion, in most cases been sincere, but due entirely to a mistaken apprehension of the nature of the causation of the actual operations and of the results of these contracts. They have saved—and this is demonstrable—to the Government a vast amount of money. They have operated with smoothness, flexibility and with surprisingly little misunderstanding or friction between the Government and the many contractors in question. Without them the vast building program of the Army which has been successfully accomplished would have been a matter of utter impossibility.

But from the very fact that they have not been understood, that their nature is not clearly seen and that the people in general, including national legislators, have

not informed themselves concerning them, they are in bad odor in many quarters, and a more or less determined effort is being made to prohibit their further use. I trust it will not be presumptuous in me to say that I am satisfied that the remedy for this state of affairs is the education of Congress and of others who oppose this or other measures because they do not understand them, and this education should not come through the education of the people at large, and the consequent infiltration of the knowledge thus disseminated into the legislative brain; the process should be reversed. The men who make the nation's laws should themselves be informed of the truth, and in matters such as this it is the province of just such societies as yours to act as the educational agency.

Technical Societies Should Join Together

This brings me to another thought which I wish to urge to the earnest consideration of this audience. It is my belief that the dignity, the power, the learning and the history of accomplishment of the engineers of this country make them a factor in its future undertakings which must in time be realized and accepted by the Government. They should be gratefully and heartily accepted by the Government as a constructive force and as an instrument of accomplishment which, properly taken advantage of, will be second to none. But, in order that the fullest good can come from such a consummation, there must be the utmost harmony, the utmost flexibility and the most thorough coöperation among the engineers themselves.

In the building operations of the Construction Division, there has never been a time when the great engineering societies of this country have not been willing and eager to lend their assistance to the work of the division, each and every one of them, and I wish here and now to tender publicly my grateful and heartfelt thanks for this invaluable assistance extended so generously and so freely. But, in every case, the War Department had to treat with a number of more or less isolated societies. In union there is strength, and there is no axiom of the many which are so freely mouthed which is so true and so universal in its application as this one. Had there been amalgamation of these societies—a consolidation, if you will—a central governing body to which they were all subsidiary, or in some shape or form a coördination, a central direction, some one head to which they all looked and with which an outside agency could treat, the task of the War Department would have been infinitely simplified. I believe that for the greatest good of the engineers, of the Government and of the economic life of this country, some such arrangement will have to be made. Concerning the form or the method, I do not know and would not presume to advise. Concerning the wisdom of such action, I am as sure as I am of anything in the world, and I urge it upon you to consider it with thought and to make it an accomplished fact as soon as may be.

The experience of this work has shown the infinite wisdom of a close *rapport* between Governmental agencies and the large commercial and professional organizations whose aid must be enlisted at any time of national crisis. Such aid has been freely given during this war, but the method of effecting its greatest accomplishment has been hindered and hampered by the fact that the parties had, at first, to establish mutual understandings, to get each other's viewpoints and to adjust themselves to a changed and unfamiliar method of accomplishing results. There should be in the future, there must be, close touch and sympathy between such organizations and the executive departments of the Government. This, I hope, will be particularly the case with the membership of the engineering societies of America.

Director General Reviews Railroad Operation for Year

General Conclusions, and Figures Furnished on Operating Results—Reasons for Adoption of Standard Locomotives and Cars

REVIEWING the past year of railroad operation under Government control Director General W. G. McAdoo's report to the President outlines the accomplishments of the Division of Operation established Feb. 9, 1918, with Carl R. Gray as director. The difficulties in operation and the causes of congestion are enumerated, and methods of attacking the problems are presented. Abstracts are presented here of the sections on coal handling, unification of terminals, short-hauling of freight, and the standardization of locomotives and cars.

In addition, details from Mr. McAdoo's report to the Interstate Commerce Committee of the United States Senate, Jan. 3, on expenditures, on unification needs at Cincinnati, and on the elimination of circuitous routes, are included.

Causes of Railroad Congestion

The potent causes which produced serious conditions of congestion and resulted in the taking over of the railroads by the Federal Government were: (1) Accumulation of export freight at North Atlantic terminals; (2) shortage of motive power; (3) heavy building operations by different branches of the Government, the contractors for which ordered materials forwarded far in advance of their ability to receive and unload them (at one time over 5000 carloads of piling were tied up in the Hog Island shipyard); (4) feverish demands led manufacturers to purchase raw materials from unusual markets, in excessive quantities, with the frequent result that arrivals were badly bunched and unloading was slow and difficult; (5) the necessity for giving priority to shipments of Government freight, and the lack of central control, and (6) the withdrawal for overseas service of Atlantic coastwise vessels.

The controlling factor throughout the experience has not been in road transportation, but at the ultimate destination, and any serious condition of congestion obtaining on any of the trunk lines en route has been the reflex of the other conditions at the terminals themselves. Practically all transportation in the United States has been based primarily upon the desires and necessities of the consignor rather than upon the ability of the consignee to receive and digest the freight.

The most serious situation presented itself in the case of bituminous coal. This condition was the result of three factors: (1) Actual shortage of cars at the

mines; (2) lack of systematic distribution, and (3) dislocation of the New England supply, the result of the withdrawal of coastwise steamships.

The bituminous coal production for the preceding year had been the largest in the history of that industry, approximating 544,000,000 tons. The severe weather conditions in January, 1918, resulted in decreased production—due almost entirely to the car supply—of 65,294 carloads. Immediate and drastic steps were taken to remedy this situation, and, notwithstanding the severe weather throughout February and March, the railroads in February produced an increase of 24,366 cars of coal over the preceding February, and for the succeeding months continued to produce large increases, to a maximum of 150,288 tons in July over the preceding month of July. The net increase for ten months was 741,665 cars; or approximately 37,080,000 tons more of coal were obtained. New England necessities have been fully met, and the largest tonnage of coal ever known—28,153,317 tons—has been moved to the Lake Erie ports and transported to the Northwest, compared with 26,826,000 tons in 1917.

A very considerable proportion of the credit for the increase must be attributed to the operation of the zone plan, which overcame the cross-hauling of coal and insured its provision from the nearest accessible market. Under this plan various bituminous coal-mining districts east of the Rocky Mountains were separated, and to each was assigned a definite territory wherein it could market its coal. Coal from any district could be shipped to destinations beyond zones allotted to that district only upon permit of the Fuel Administration.

The coal-zoning plan not merely saved car-miles, but in addition permitted the utilization of coal produced in the plains states which would not otherwise have been produced.

Shortage of Foodstuffs

A program had been arranged by the Food Administration by which approximately 1,160,000 tons of food per month were to be forwarded to the Allies. Early in February it was found that only 750,000 tons had been forwarded in January, and at the same rate of progress only 500,000 would have been forwarded in February. Empty box cars were moved in preference from all sources in the East and South into the Western grain states, with the result that by Mar. 15 the vessel capacity of the allies had been satisfied and there was available at North Atlantic ports an excess on wheels of 6318 cars of foodstuffs, exclusive of grain on cars or in elevators.

To simplify and economize the methods of transportation, the following actions were taken under unified control:

Unification of terminals was made general throughout the country at both large and small stations; terminal managers have been appointed for the larger terminals, and where unnecessary mileage was not involved a consistent effort was made to route freight so as to arrive at the specific terminal where it is to be disposed of. Interchange switching in terminals has been eliminated, so far as this was practicable.

The following are typical examples of what has been done by unification:

1. The Southern Pacific, Atchison, Topeka & Santa Fé, and the Western Pacific, each maintained passenger ferry service between Oakland and San Francisco. The Santa Fé and Western Pacific passenger trains have been brought into the Oakland mole of the Southern Pacific. The latter's railroad facilities were ample for the three lines. Dispensing with the ferry service of the other two effected an approximate saving of $315,000 per annum. All railroad and marine facilities in New York harbor were consolidated under a marine manager and have been used in common. One hundred and seventeen coal-carrying barges and 18 tugs belonging to the Philadelphia & Reading, Lehigh Valley, New York, Ontario & Western, and Erie Railroads were pooled under a single management. All passenger trains of the Baltimore & Ohio and through passenger trains of the Lehigh Valley were brought into the Pennsylvania R.R. terminal in New York City.

2. Short-hauling of freight has been consistently followed, except where better grade conditions and less congestion were favorable factors on a somewhat longer line. An instance is the Northwestern region, where the correction of improper routing within a period of five months showed a saving of 4,054,455 car-miles on 34,941 carloads.

3. Solid trains for definite destinations were made up at Chicago, Minneapolis, St. Paul, St. Louis and at Missouri River crossings, resulting in a decrease in intermediate terminal switching and the expedition of essential Government freight.

4. Nonessential passenger trains have been eliminated, with the result that the number of trains discontinued resulted in a saving per year in passenger-train miles of 16,254,000 in the Eastern region, and a maximum of 23,280,000 in the Northwestern region.

5. Common use of freight cars.

6. Common use of repair shops.

7. The New York tubes were utilized for the movement of anthracite coal from New Jersey terminals to Long Island, affording substantial relief at a most critical time. Under its franchise this could not have been done by the Pennsylvania R.R. under private operation.

The enormous tonnage which is handled locally at the Pittsburgh gateway makes it very difficult to use it for trunk-line traffic. The trunk-line railroads through Pittsburgh should be relieved by the construction of an entirely new freight line connecting them east and west of Pittsburgh, but entirely avoiding the industrial area.

Condition of Equipment

The extended period of heavy business. high prices for material, difficulty in obtaining sufficient labor, loss of many experienced mechanics through the selective draft, followed by an early and unusually severe winter in 1917-18, resulted in a generally defective condition of locomotives and cars. The remedy was not so much the building of new locomotives and cars as the proper maintenance of those in service, and more prompt movement of trains. It was found that shop facilities were sufficient if efficiently used; therefore, the task of

nationalizing these facilities and assigning locomotives to shops where repairs could be made regardless of ownership was assigned to the chief inspector of the Bureau of Locomotive Inspection.

Roundhouses built 20 or more years ago were still being used to house locomotives more than twice the size of those for which they were designed. Repairs had to be made either out of doors or in open roundhouses at a temperature below zero. On the Baltimore & Ohio R.R. 133 locomotives froze up in the period from Dec. 28, 1917, to Jan. 5, 1918. In spite of these conditions, the situation immediately began to improve under the plan organized by the mechanical department of the Railroad Administration. After successful solution of certain labor difficulties, there was a noticeable increase in the production of the shops and engine houses where disputes had occurred. The average increase in locomotive-shop hours for the entire country amounted to about 16 per cent.

Standardized Locomotives

Designs were worked out for standardized locomotives, and orders for 1430 were given. These locomotives were built from standardized designs for the following reasons: To reduce to a minimum the time required to prepare drawings, patterns, and dies; to secure quantity deliveries—the increased production due to the standardized locomotives was about 50 per cent.; to provide a supply of equipment the parts of which are largely interchangeable and available for use anywhere in the event of congestion.

The freight-car situation was handled along the same lines, and after careful consideration designs were prepared and orders placed for 25,000 self-clearing steel hopper cars of 55 tons capacity, 25,000 single-sheathed box cars of 50 tons capacity, 25,000 double-sheathed box cars of 40 tons capacity, 20,000 composite gondolas of 50 tons capacity, with drop doors, and 5000 low-side gondolas of 70 tons capacity. In addition, many designs for other freight cars and steel baggage cars were made.

Instead of hauling new locomotives dead, orders were issued that wherever possible they should be moved under steam, hauling trains where practicable. This order relieved the railroads from 500,000,000 ton-miles of transportation annually for material which not only should be self-propelling, but should haul additional freight. The terminal facilities for the maintenance of locomotives and cars were consolidated at 417 points, and the annual saving effected thereby amounts to $2,363,500. Additional consolidations are under way. At one large shop the output of locomotives receiving classified repairs increased over 50%, and increases ranging from 10% to 25% were secured in many shops.

By rearranging methods of handling locomotives at terminals, it was possible to overcome what otherwise would have been a shortage in motive power. For example, on one railroad an appeal was made for an additional assignment of 25 Mallet locomotives, but by changing the method of handling at important terminals delay was reduced, and this road was able to release for service on other lines nine locomotives instead of requiring extra ones. There are now in reserve 1021 locomotives in various regions, and there are in storage 150 new standardized locomotives recently received to furnish surplus power to pass through the present winter.

In his report to the Interstate Commerce Committee of the United States Senate, Jan. 3, Mr. McAdoo included the following detailed figures on expenditures, on the elimination of circuitous routes, and on the special unification problem at Cincinnati.

The total improvements on all lines under Federal control, authorized to Dec. 1, 1918, amounted to $1,254,396,158, of which $656,058,745 was authorized for equipment. For this work expenditures had been made up to Nov. 1, 1918, of $477,211,012, of which $248,442,873 was for equipment.

The elimination of many circuitous routes in the handling of freight traffic has resulted in efficiency which cannot be measured only by the car-miles saved through diversions of freight in transit. The saving in distance by many of the new routes is great; for example, one from Los Angeles to Dallas and Fort Worth is over 500 miles shorter than that formerly used; another from the oil fields of Casper, Wyo., to Montana and Washington State points, is 880 miles shorter; fruit from southern California to Ogden is hauled 201 miles less and a new route between Kansas City and Galveston has been developed which is 289 miles shorter than the 1121 miles previously traversed by one line. The ore traffic moving from Minneapolis and Michigan mines to Lake Superior and Lake Michigan ports was rerouted. During the shipping season a total of 64,770 loaded and empty cars were rerouted with a saving of 3,577,464 car-miles.

Difficulties in Terminal Unification

A concrete illustration emphasizes the present difficulties in terminal unification: Three important railroads reach Cincinnati by crossing the Ohio River and four other important railroads reach it on the north bank of the Ohio River. The interchange of traffic between these lines at Cincinnati is enormous, and the conditions are such that in times of heavy traffic the freight at Cincinnati is badly congested. Under private management these railroads have never been able to get together and put into effect any comprehensive plan which would result in terminal facilities equal to the situation.

At the present time there are perhaps 25 or 30 freight houses in and around Cincinnati which have been provided primarily for the particular use of the separate railroad companies. It is estimated that there ought to be spent in the near future about $45,000,000 in the rehabilitation of Cincinnati terminals so as to make them equal to modern public needs, with probably $25,000,000 additional for passenger terminals. This involves the building of a new bridge and the reconstruction and enlargement of two other bridges, the construction of convenient and commodious freight houses, the provision of adequate belt lines and adequate facilities for intercommunication between the various railroads.

By the establishement of a permit system whereby traffic is not allowed to be loaded except upon showing that it can be delivered to the consignee at destination, there was effected practically a complete absence of congestion during the autumn months of 1918 when traffic was at its heaviest.

Find Cause of Obnoxious Tastes in Milwaukee Water

Coal Tar Derivatives from Coke and Phenol Plants Produce Taste When Diluted One Part in 500 Million

By H. P. Bohmann
Superintendent, Milwaukee Water-Works

FOR a number of years, but particularly during the present year, the water-supply of Milwaukee has been under discussion, owing to the obnoxious taste and odor present at times, and frequently referred to as a "medicinal taste" or a taste similar to that of iodoform or carbolic acid. During 1918 the taste and odor were so nauseating at times as to make the water absolutely unfit for drinking and cooking purposes, as the taste remained in the water even after boiling. In fact, the taste seemed more pronounced after the water was boiled. At first these odors and tastes were attributed to the use of chlorine in disinfecting our water-supply, and whenever the taste appeared the quantity of chlorine was reduced, although it was soon discovered that the taste frequently appeared when smaller quantities of chlorine were used, and was absent when larger quantities were being applied. It was also discovered that these objectionable tastes and odors were always accompanied by south or southwest winds, which blow the contaminated water from the harbor outlet, where the three rivers which flow through the city unite and discharge their sewage-laden contents into the lake, towards the water intake, which is only 3½ miles from the harbor outlet, in a northeasterly direction.

As the chlorine treatment is carefully supervised by a competent chemist, and the tastes and odors occurred only when the wind was from a certain direction, we were convinced that they were not due to the use of chlorine alone, but that the action of the chlorine on some of the organic matter present in the polluted lake water formed compounds that produced taste and odor. That chlorine in the quantities used (0.22 to 0.34 ppm.) did not produce the tastes and odors was also apparent from the fact that taste and odor were present on days when the free chlorine in the tap water in various parts of the city was low, and absent on other days when the free chlorine was 50% greater, although the quantity of chlorine applied was the same on both dates. Furthermore, the water of South Milwaukee, with a filtered supply, and using one-half the quantity of chlorine applied at Milwaukee, had the same obnoxious taste when wind conditions were favorable.

Suggestion at Water-Works Convention

In discussing the matter of tastes in water-supplies with a member of the American Water-Works Association in 1917 I learned that he had experienced trouble similar to ours, and that he attributed it to the industrial waste, from a coke plant, which was getting into his water-supply. With this information as a key to a possible solution of our troubles, samples were taken of the effluents being discharged at the local coke and gas plants. In the water-works laboratory chlorine was added to a sample of tasteless raw water until the ortho-tolidin test showed 0.09 ppm. of free chlorine in the sample, this amount of free chlorine representing the maximum that the tap water has ever contained. The addition of chlorine did not produce any taste in the sample. After the addition of some of the effluent from the coke plant to the chlorinated sample, the sample had a decided taste, resembling that of coal-tar derivatives, and was almost identical with the characteristic taste at times present in our water-supply. The sample was then boiled and cooled to its former temperature. The ortho-tolidin test then showed no free chlorine present, while the taste was stronger than before the boiling.

The results of the initial test of the first three samples pointed to coal-tar derivative wastes in combination with the chlorine added to our water-supply. These substitutive or additive compounds are probably the direct cause of the taste in the water. Such compounds boil at a higher temperature than water, and, therefore, would not be expelled in boiling.

Joint Investigation Made

At this point in the experimental work, all further investigations of the cause of the taste in the city water were carried on jointly by Robert L. Piper, chemist of the water-works, and Russell W. Cunliffe, chemist of the Health Department. Nearly 900 samples of sewage and trade waste were obtained and tested for taste in the manner above described, since, when greatly diluted in the lake, it is impossible to prove the presence of these substances by any chemical determination. These samples represented trade waste effluents and sewage of every description, such as those from hospitals, tanneries, packing houses, glue works, and from intercepting sewers carrying sewage from metal works, breweries, homes, etc.; also from gas plants, coke plants, and chemical industries manufacturing coal-tar products.

The results of the tests clearly indicated that the tastes and odors complained of in the water supply of Milwaukee are due to coal-tar derivative wastes from industrial plants, in combination with the chlorine used by the city for the purification of its drinking-water supply. It is only from samples of effluents of a coal-tar derivative nature that the characteristic and obnoxious taste present at times in our water-supply could be reproduced in the laboratory. All other samples failed to produce this taste. It was possible to add sufficient chlorine to a sample of tasteless raw water to produce a chlorine taste, which, however, is quite different from the taste complained of. This chlorine taste could, in every instance, be removed by boiling, or neutralized by sodium thiosulphate. The objectionable taste complained of in the water, however, could not be removed by either of these two methods. Furthermore, tests on solutions of tasteless raw lake water and various substances, such as naphthalene, benzol, phenol, petroleum oil, etc., demonstrated that upon chlorination only do these solutions which contain substances of coal-tar derivation produce tastes; in other words, only those substances which are or may be present in the taste-producing effluents mentioned above. There are, undoubtedly, substances of coal-tar derivation other than those mentioned which, when combined with chlorine, would form taste-producing bodies.

A survey made of all industrial plants whose industrial wastes contained objectionable elements of coal-tar derivation indicated that in addition to the local coke and gas plants there were five plants located outside of the city whose effluent might possibly contribute to our water pollution. Of these, three were at Carrollville, which is about 8 miles south of our southern city limits, and about 13 miles distant from our water intake. These plants were under suspicion from the start as contributors to our trouble, although it was impossible for a long time to establish this fact, owing to the difficulty of obtaining samples out in the lake when wind conditions were favorable. However, at a later trip, the fact was established beyond doubt, as samples were obtained at various points in the lake between the water intake and Carrollville, which upon chlorination produced the objectionable taste in varying degrees.

One of the three plants at Carrollville was engaged in the production of phenol for the United States Government, partly in its own plant and partly in a building owned by the Government. The combined production of phenol in the two plants, which originally amounted to only a few tons a day, had greatly increased until, during October, 1918, it amounted to 130 tons daily. It was estimated by the management that the daily trade waste flowing into the lake contained anywhere from 1100 to 2200 lb. of phenol, and the management was inclined to believe that the latter figure was more nearly correct. The possibilities of producing taste in a water-supply can best be appreciated when we learn that taste can be produced, after chlorination, in solutions containing one part of phenol to 500,000,000 parts of water. This amount of phenol could pollute from 60,000,000,000 to 120,000,000,000 gal. of water to such an extent that taste could be produced upon chlorination.

Appeal Made to State and Federal Authorities

When the obnoxious taste again appeared in a very acute form, early in November, an appeal was made to the State Board of Health to assist the local officials in obtaining immediate measures of relief. Telegrams were sent by Mayor D. W. Hoan to Dr. Rupert Blue, surgeon general, United States Public Health Service, and Newton D. Baker, secretary of war, asking them to lend their assistance, as it was asserted that some of the companies were engaged in Government work. A meeting was held in the mayor's office, which was attended by Governor Philipp, city and state officials and representatives of the coke and gas companies. After a general discussion of the subject, Governor Philipp suggested that the mayor appoint a committee to study the report made by the chemists, visit all of the plants under suspicion and, if possible, place the responsibility for the obnoxious taste. The mayor then made the following appointments: Dr. C. A. Harper, state health officer, and Prof. J. C. D. Mack, state chief engineer, representing the state; Dr. George C. Ruhland, health commissioner, H. P. Bohmann, superintendent of water-works, and William R. Copeland, chief chemist of the Sewerage Commission, representing the City of Milwaukee; R. B. Brown, general manager and chief engineer of the Milwaukee Gas Light Co.; J. W. Shaffer, vice-president in charge of operation of the Milwaukee Coke and Gas Co., the Newport Hydro-Carbon Co. and the Newport Chemical Works, Inc., representing the industrial plants.

The committee visited the various plants, and testimony was taken at each plant by Dr. C. A. Harper, state health officer. Later a meeting of the committee was held at Madison, at which the committee framed its formal report. The conclusions were:

Carbolic-Acid Plant Wastes

"That, from its personal investigation and from a careful study of the reports that have been worked out by the chemists of the water department, the health department and industrial companies, the obnoxious odor and taste complained of in the Milwaukee water-supply are essentially attributable to the effluent coming from the Newport Hydro-Carbon Co., a plant engaged in the manufacture of carbolic acid. It finds its belief substantiated in the fact that from Nov. 26 to Nov. 29, during southerly winds, when operations of the plant were suspended, there was no recurrence of the nuisance in the city's drinking water."

Since the latter date the plant of the Newport Hydro-Carbon Co. has been permanently closed, and no more phenol will be produced there. This will undoubtedly remove the largest factor in our water trouble.

The next largest contributor was the coke company, where it was estimated that about 91 lb. of phenol was discharged daily with its industrial waste. It was estimated that the amount of trade waste having taste-producing properties leaving the coke plant daily was sufficient to impart taste, of the kind complained of in our water-supply, to 10,000,000,000 to 40,000,000,000 gal. of water. The other plants contribute to this pollution according to the volume of the effluents discharged from their respective plants, all of them, however, to a far less degree. The taste-producing properties of the effluents of the plants investigated were found to range from dilutions of 1 to 100 to 1 to 400,000.

Basing opinion on the results of the many tests made, it is reasonable to assume that any water-supply which is being chlorinated, and which occasionally has a medicinal or phenol-like taste which cannot be removed by boiling, may have been contaminated with waste material produced in the destructive distillation of coal and in the recovery and manufacture of the byproducts of this process; otherwise, it should be possible to remove the taste by boiling. The only practical method known at the present time to avoid taste of this nature is to keep this particular kind of effluent out of a water-supply. No water-supply which is polluted with coal-tar derivatives and where chlorine is used as a sterilizing agent can be made palatable for drinking purposes. It is possible that by laboratory experiments some chemical may be found which will overcome the affinity of chlorine for the coal-tar bodies or change their composition so that they will not unite with chlorine. Every effort is being made by the coke and gas companies to find a method of taking care of their wastes.

Undoubtedly, some of the readers of *Engineering News-Record* know that the City of Milwaukee has planned an extensive program for improving its water-supply. With that program carried out Milwaukee can be assured of the best of water-supplies.

Light and Heavy Equipment Compared on Identical Sewer Construction

Field Costs per Unit of Sewer Are Substantially the Same for Both Plants—Greater Speed Possible with Heavier Plant, According to Results Obtained

By Ralph H. Burke

Division Engineer in charge of Sewer Work, Sanitary District of Chicago

Direct comparison of efficiency of heavy and of light equipment in nearly identical operations is afforded by the construction of the Calumet intercepting sewer for the Sanitary District of Chicago. Field construction costs per unit of completed sewer, based on the working conditions prevailing during four months in 1917 and using figures which do not apply to the whole work on either contract, averaged about the same for both sizes of plant. Speed of construction, however, was about 65% greater with the heavier equipment. It also required a 25% larger working force and cost about 17% more per day to operate than did the lighter outfit.

The preceding figures do not include the installation of equipment, special work at curves or crossings, or other items peculiar to the individual contract section. Also, they cover only the operations in the field, and do not include general expenses such as overhead, insurance, bonding and general administration charges. It should be repeated that the figures are comparative only, and do not represent the total costs for all work on either section.

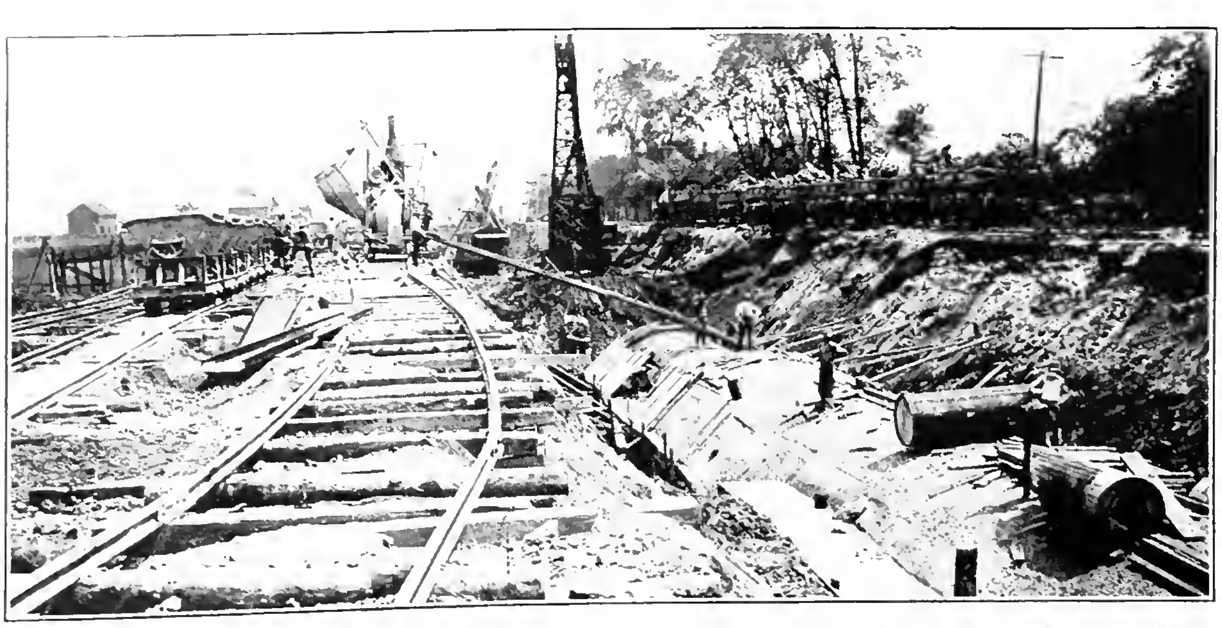
The Calumet intercepting sewer extends from South Chicago to the Calumet-Sag Channel near Blue Island, a distance of about nine miles. The total cost of the project is approximately $3,600,000. The sewer section is concrete, of horseshoe shape, with a rather flat invert and a semi-circular crown, and varies in size from 11 ft. to 17½ ft. internal width. The cuts are comparatively shallow on the easterly three miles, ranging from 14 to 18 ft., while on the westerly six miles the cut is about 30 ft. The material encountered consists of sand and sandy clay in the shallow cut, and chiefly clay, varying from soft to very hard, in the deep cut. The work is located largely through sparsely settled territory, where ample room is available for the operation of the plant. The construction has required the use of plant not ordinarily employed on sewer work in the vicinity of Chicago. The excessive width and depth of the cut preclude vertical trenching. The cost of timbering to support a steam shovel or other excavating plant capable of handling work of this size would be prohibitive. On the shallow cut, dragline excavators were employed for the entire excavation, while on the deep cut the work has been divided into two lifts, the upper lift being excavated by a steam shovel, the lower lift by a dragline moving along the bottom of the shovel cut. This method requires the sloping of the sides of the top cut not only to avoid continuous bracing, but also to allow sufficient width for the operation of the dragline. That portion of the cut below the haunches of the sewer section is vertical, as nearly as possible, and, in general, the concrete is placed against the earth without the use of back forms. The typical sections illustrated indicate the general proportions and dimensions of the work.

TABLE I. CONSTRUCTION PLANTS ON SECTIONS 4 AND 7, CALUMET INTERCEPTING SEWER

(Four Months during 1917)

Section 4	Section 7
Excavating Plant	
1. Thew revolving steam shovel, size 0; 1-cu.yd. bucket.	1. Marion standard steam shovel, model 76; 40-ft. boom, 40-ft. dipper-handle, 2½-cu.yd. bucket.
. Lidgerwood dragline; 70-ft. boom; 2-cu.yd. Page bucket.	2. Bucyrus dragline, class 14; 65-ft. boom; 2½-cu.yd. Page bucket.
3. Fifteen 1½-cu.yd. dump wagons; 16 wooden, side-dump, 4-cu.yd. cars; 1 mile 36-in. gage track, 45-lb. rails; two 14-ton Davenport locomotives.	3. Thirty-six 6-cu.yd. Western dump cars, automatic couplers; two miles standard-gage track, 60-lb. rails; four 25-ton Vulcan locomotives.
Backfilling Plant	
Timber revolving derrick with ¾-cu.yd. orange-peel bucket.	Western Wheeled Scraper Co. standard-gage spreader.
Concrete Plant	
Overhead 400-cu.yd. bins; 2000-bbl. cement house; derrick car with ¾-cu.yd. clamshell; 75 Koppel 27-ft. steel dump cars; 2 Chain Belt mixers, 1-cu.yd.; 150 lin.ft. collapsible Blaw steel forms with traveler; 1 mile 20-in. gage track, 25-lb. rail.	Overhead 600-cu.yd. bins; 2500-bbl. cement house; Brown Hoist 15-ton locomotive crane with 1½-cu.yd. clamshell bucket; 30 Easton steel dump cars 40 cu.ft., three 8-ton Vulcan locomotives; 2 Foote 40-cu.ft. mixers; 175 lin.ft. collapsible Blaw steel forms with traveler equipped with 6-hp. Fairbanks-Morse gasoline engine for moving; 2 miles 36-in. gage track, 50-lb. rail.

The work was divided into contract sections, each with a length of about a mile and a half. The plant employed is quite similar in character on all sections, but differs in details and as to the sizes of the main units. A direct comparison can, however, be made between large and small plant units, both similar in type, and both employed on work of equal magnitude. This opportunity is exceptional, since each construction job



CONSTRUCTION PLANT ON SECTION 7 DISTINGUISHED BY HEAVY EQUIPMENT UNITS

usually presents problems peculiar to itself, requiring certain adaptations of ordinary contractor's equipment not called for on other work. Also, the results cbtained in each case ordinarily cannot be applied to other work without allowances for the different requirements. On the Calumet sewer, however, the work under the separate contracts is almost identical in magnitude and as regards working conditions; the plant employed is similar in character and operation, and a comparison of results can be made without the usual introduction of inexact and unknown factors which so vitally affect costs.

Sec. No. 4 and Sec. No. 7 of the Calumet intercepting sewer were built, respectively, by Nash Bros. and by the T. J. Forschner Contracting Co., both of Chicago. Both contract sections have been handled very efficiently, and the finished work in both cases is of the highest grade in every respect. The cut in both cases was about 30 ft. The sewer section has an internal width of 16½ ft. on Sec. 4 and 16 ft. on Sec. 7.

Excavation in both cases was performed in two lifts; the top lift, about 10 ft. in depth, was handled on Sec. 4 by a small revolving steam shovel, loading dump wagons, while on Sec. 7 a large standard steam shovel was used, loading standard-gage dump cars. The bottom lift on both sections was handled by a medium-sized dragline excavator. On Sec. 4 the earth was piled on one side of the cut and was also loaded into narrow-gage 4-cu.yd. dump cars, while on Sec. 7 it was loaded into standard-gage 6-cu.yd. dump cars.

Backfilling was done with the earth excavated from the bottom cut. On some parts of Sec. 4 the earth stored along the side of the cut was placed in backfill by a revolving derrick equipped with an orange-peel bucket, while on other parts of the work the earth was hauled directly to backfill in dump cars and spread by hand. On Sec. 7 the dump cars transported the excavated material directly to backfill, grading being accomplished by a standard-gage spreader.

The concrete was placed on both sections by two batch mixers moving along one side of the cut. Crushed stone and sand were unloaded from the railroad cars and placed in overhead bins, a derrick-car equipped with clamshell bucket being employed on Sec. 4, while a locomotive crane with clamshell bucket was used on Sec. 7. The batches were proportioned at the bins by filling small steel dump cars with sand, stone and cement, each carload forming a batch of concrete. The cars passed under the bins and were filled by gates with the exact batch amount of sand and stone. The cement was charged by tipping buckets, each holding cement for one batch. The cars on Sec. 4 held 27 cu.ft. and operated on a 20-in. gage track, being hauled in trains of nine cars by means of horses. On Sec. 7 the cars held 40 cu.ft. and operated on a 36-in.-gage track, being hauled in trains of 12 cars by means of dinkey engines. From July to October, 1917, work on both sections progressed without interruption and without special features peculiar to either. Costs and output of the two plants during this period are therefore strictly comparable.

TABLE II. CONSTRUCTION ORGANIZATION ON SECTIONS 4 AND 7 CALUMET INTERCEPTING SEWER

(Four Months during 1917)

SUBSTANTIALLY IDENTICAL CHARACTER OF WORK INDICATED BY COMPARATIVE DIAGRAMS

The average progress per working day was 25 lin.ft. of completed sewer on Sec. 4 and 41 lin.ft. on Sec. 7. The average force employed was 80 men on Sec. 4 and 100 men on Sec. 7. Labor costs averaged about $382 per day on Sec. 4 as compared with $407 per day on Sec. 7. Plant costs amounted to $135 per day on Sec. 4 and $200 per day on Sec. 7. The plant costs include all those of operation, such as coal, oil and other supplies, and include also an allowance for interest, maintenance and depreciation averaging about 5% per month on the value of the plant.

NARROW-GAGE TRACK AND LIGHT EQUIPMENT EMPLOYED ON SECTION 4

Summarizing and charging all costs against the two main items, excavation and concrete, the unit costs are as follows:

Item:	Sec. 4	Sec. 7
Excavation, per cubic yard	$0.40	$0.28
Concrete, per cubic yard	5.91	5.27

The quantities upon which these figures are based are the actual quantities, as shown by the accompanying typical cross-sections.

Based on the linear feet of completed sewer, the cost is $44.50 per foot on Sec. 4 and $44.15 per foot on Sec. 7.

Comparison of the items which make up the preceding totals is presented in the three accompanying tabulations.

The construction of the Calumet intercepting sewer is under the direction of the engineering department of the Sanitary District of Chicago, of which G. M. Wisner is chief engineer and the writer is division engineer, in charge of sewer work.

Accidents on Railroads Reported by Interstate Commerce Commission

DURING the year which ended June 30, 1918, there were 91 train accidents investigated by the Interstate Commerce Commission, according to the latest annual report. In these accidents, comprising 63 collisions and 28 derailments, 374 persons were killed and 1730 were injured; 26 collisions occurred on block-signal lines, 13 in automatic block-signal territory, and 13 in nonautomatic block-signal territory, five occurred on track where yard rules were in effect, and 31 occurred on lines operated by the train-order and time-interval system.

Of the 13 collisions which occurred in automatic block-signal territory, eight were due to failure of enginemen to heed automatic indications, and one was caused by failure of the train crew to obey a rule; in the other four cases, the signal system in use was not involved, two of these being due to trains running away on mountain grades and two involving trains running against the current of traffic, which movements were governed by train orders.

The most disastrous accident during the year resulted in the deaths of 60 persons and the injury of 128, and occurred on a line operated by a modern automatic block-signal system; it was caused by an engineman falling asleep and failing to see a stop signal. Since accident investigations were begun by the Interstate Commerce Commission in 1911 approximately 10 per cent. of the total number investigated were caused primarily by the disregard of signal indications. As many of these accidents occurred on lines equipped with the best signal systems, properly installed and maintained, the urgent need of some further safeguards, such as automatic devices designed to compel obedience to signal indications, is apparent.

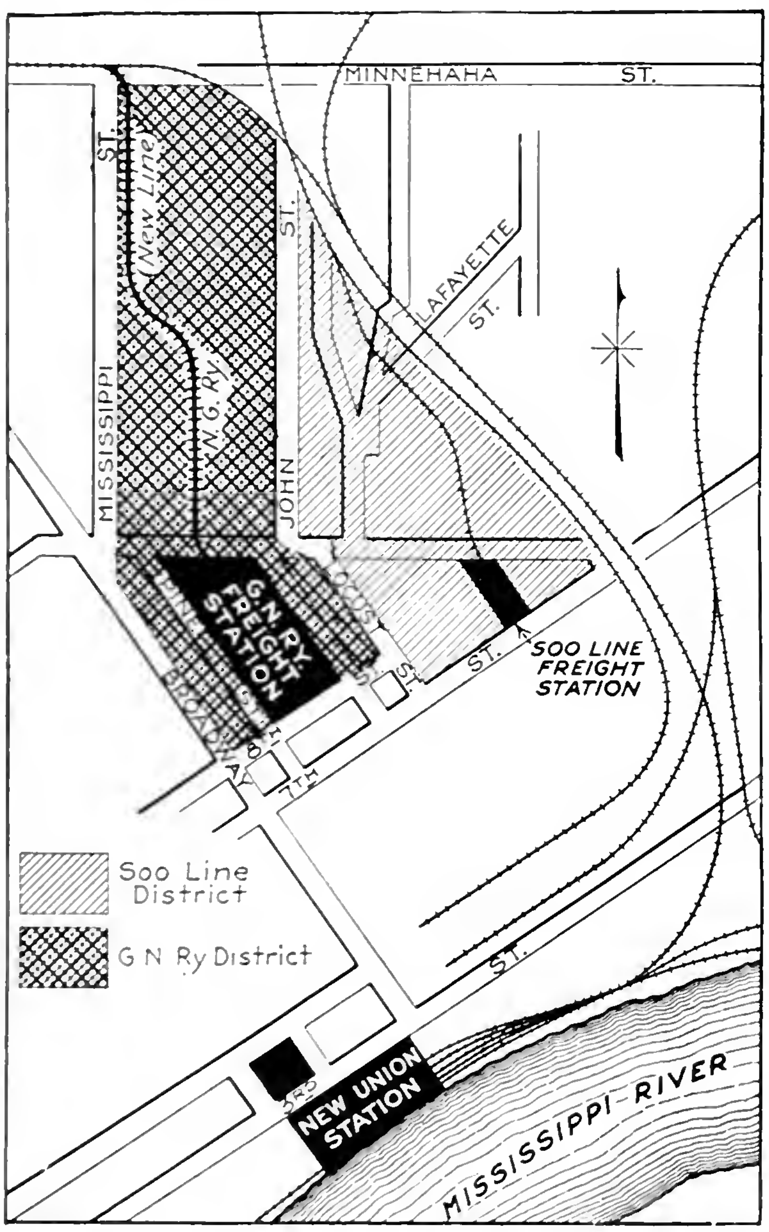
Approximately half of the collisions investigated during the year occurred on lines operated by the train-order and time-interval system; many of them were due to the inherent weaknesses of that system. Nine were due to errors in issuing, transmitting, or observing train orders; seven were caused by a train occupying the main track on the time of superior trains without proper protection; and seven others were caused by failure of flagmen to protect their trains properly; four were caused by failure of enginemen to obey prescribed speed restrictions, and four were due to purely local conditions and causes. It is stated that many of the collisions investigated during the year could have been prevented by the proper application of the block-signal principles, and it is beyond question that the adoption of the block system on lines now operated by the train-order system would result in a material reduction in the annual casualty record.

Of the 28 derailments investigated, 17 were caused by defective track and three were due to defective equipment; in three other cases the speed of trains was the primary cause, and in three cases the derailments occurred on account of local conditions.

Railways Form Industrial District At St. Paul

Over One Hundred Acres Used for Manufacturing and Freight Terminals Being Developed Near New Station

ESTABLISHMENT of an industrial district of about 117 acres at St. Paul, Minn., containing also the freight terminals of two railways, has been effected in connection with the new freight station of the Great Northern Ry., adjacent to similar facilities already provided by the Minneapolis, St. Paul & Sault St. Marie Ry. This is an important part of the improvement resulting from the construction of the new union passenger station. The area taken for this station included the freight terminal of the Great Northern Ry., and it became necessary to obtain a new location for the latter.



NEW INDUSTRIAL AND TERMINAL DISTRICT IS ESTABLISHED AT ST. PAUL, MINN.

Advantage was taken of this opportunity to establish an industrial district tributary to the new freight terminal. For this purpose the railway company acquired possession of the 85-acre oblong tract shown by the heavily shaded area on the accompanying map. The area lightly shaded is that of the other railway mentioned. All the buildings in this new territory have been or will be torn down, and the ground will be used for warehouses, manufacturing plants and trackage. No definite layout for the district has been adopted as yet. The upper or narrower portion, lying between Mississippi St. and the tracks, is high ground, rising to an elevation of about 90 ft. above the graded site. The material to be excavated is mainly gravel and clay, and will be used in 1919 as filling for the elevation of tracks leading to the new union passenger station.

Both inbound and outbound freight will be handled at the new terminal. The freight house, however, is essentially an inbound house, as about 80 per cent. of the outbound freight is handled on the team tracks. This freight is loaded into jumbo cars 60 ft. long, having two doors on each side, and is taken to Hamline Transfer, midway between the business centers of St. Paul and Minneapolis, where carloads are made up for the same shipping points. For handling the inbound freight and approximately 20 per cent. of the outbound freight, there is a one-story freight house 60 x 803 ft., with its long side fronting on Pine St. A 10-ft. transfer platform, 740 ft. long, lies parallel with this, and between it and the building are four stub tracks spaced 13 ft. on centers.

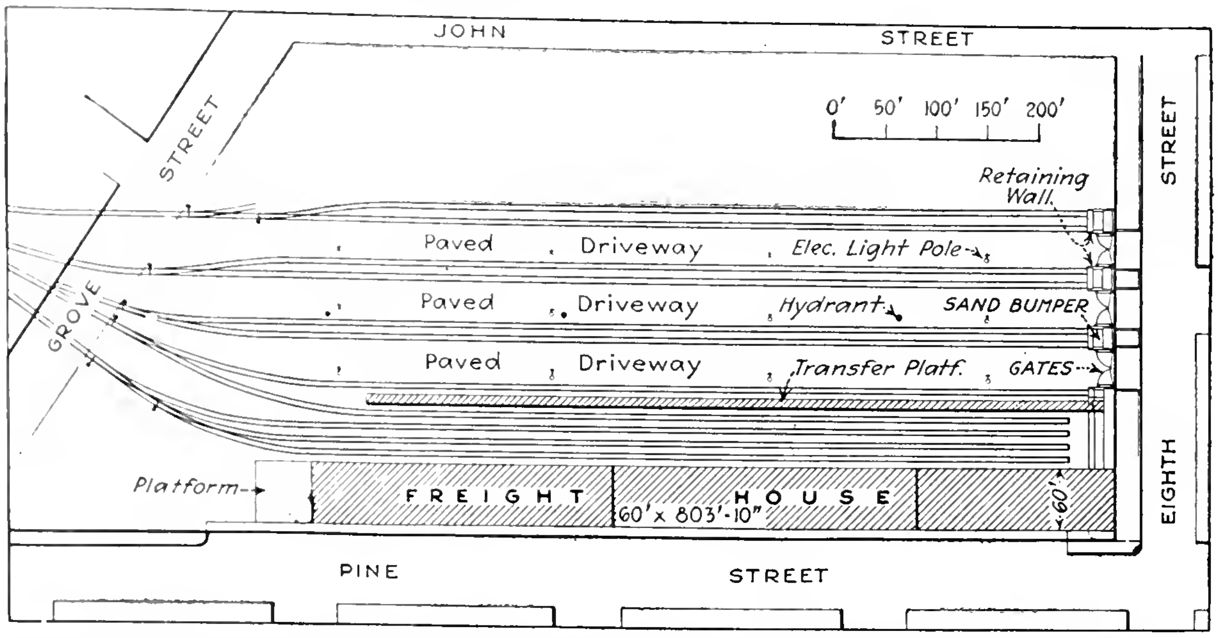
Beyond the transfer platform is the team yard, with seven tracks and three driveways, while beyond these there is room for additional trackage. Concrete curbs are placed along the driveways from which the brick-paved surface slopes down to form a central gutter, with catchbasins and sewer connections. Sand bumpers form effective stops at the ends of the team tracks. These are fills about 4 ft. deep, confined between retaining walls at the sides of the driveways. Lighting of the team yard is provided by 500-watt lamps on arms carried by 35-ft. poles, spaced 215 ft. along the driveways, the lamps being about 22 ft. above the pavement.

Brick walls and timber roof construction are used for the freight house. Its track side is entirely open, except for steel columns spaced 18 ft. 11 in. on centers and carrying a continuous reinforced-concrete lintel. The openings are fitted with steel doors which roll up behind the lintel. On the team, or street, side are 8-ft. doorways spaced 20 ft. on centers. These are fitted with steel doors which swing up on the inside but are so hung as to require a minimum of clearance space for their movements. Two firewalls divide the main floor into three sections. Owing to snow troubles, no outside platform is used on either side of the freight house. (See illustration, next page.)

A basement 300 ft. long includes a refrigerator room and a boiler room, and coal and oil storage and warehouse space, this last being served by two elevators. The basement is of concrete, with walls and columns supporting beams and girders which carry a 6-in. concrete deck slab designed for 500-lb. live load and 100-lb. dead load. Creosoted block paving 2½ in. thick covers the entire floor of the freight house. To facilitate trucking the floor has a slope of ¼ in. to the foot from the track side to the team side. The roof has plank sheathing, with tar and gravel covering, and is designed for 40-lb. live load and 20-lb. dead load. Timber construction is used for the transfer platform. Its roof is supported by side posts or bents with 20-ft. spacing, so that there is very little obstruction to movements of trucking.

A two-story section at one end of the freight house

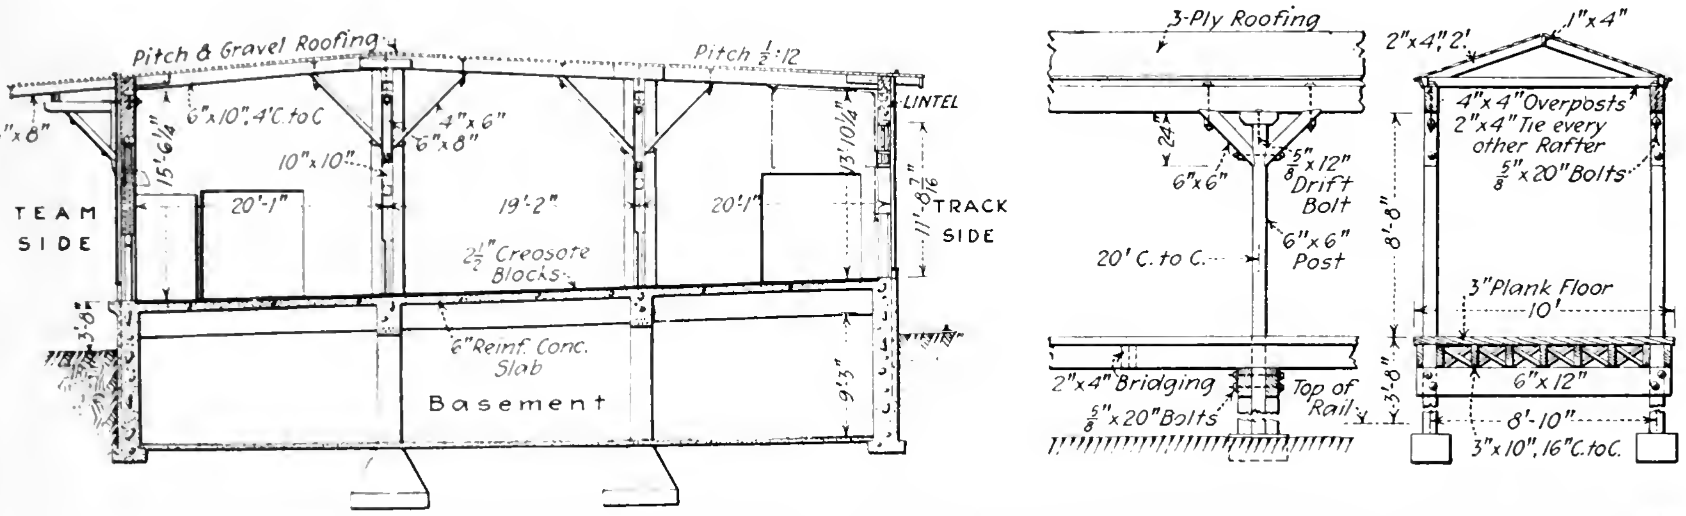
has the cashier's office on the first floor, convenient for public use. Above this are the general offices with separate locker, lunch and toilet rooms for men and women. On this floor also are a lunch room and a toilet room, with shower baths, for the freight house force, these latter accommodations being accessible directly from the main floor. Good street accommodation, permitting teams to stand at the station without interfering with traffic, is provided by paving Pine St. for a width of 63 ft. along the entire front of the freight house. The city paid for 40 ft. of roadway proper and the railroad paid for the 13-ft. boulevard or parkway and for a 10-ft. additional strip between the building and the property line. Brick paving is used, with a uniform slope from the freight house to the center of the 40-ft. roadway, beyond which the remaining 20 ft. of width has a parabolic section with a drop of 6 in. from the crown to the curb.



FREIGHT TERMINAL OF THE GREAT NORTHERN RAILWAY AT ST. PAUL IS MAINLY FOR INBOUND FREIGHT

Adjacent to the 85-acre industrial district noted above is a similar district of about 32 acres, being developed by the Minneapolis, St. Paul & Sault Ste. Marie Ry. an arterial street to the northeastern part of the city.

Making compensation for public property taken is included in the negotiations. This new industrial district replaces an old residential district, and its clearing required the abandonment of three churches, a parochial school, three public schools and a city fire station. The school department has been compensated by the Great Northern Ry. by the payment into the city treasury of $125,000 in cash and by the giving of a deed to a new site for one of the schools. The company has also purchased a site for the fire station, and will



ROLLING DOORS FORM ONE SIDE OF FREIGHT HOUSE—TRANSFER PLATFORM HAS UNOBSTRUCTED TRUCKING AREA

This includes the railway's freight terminal, built a few years ago. This gives a total of 117 acres in one area for industrial and manufacturing purposes and railway terminals.

The street layout has been improved materially in connection with this Great Northern development. Several streets and alleys in the terminal site were vacated and other streets widened or extended to improve the traffic facilities, while 14th St. is to be extended through to Lafayette Ave. A street-car line which crossed the station site has been rerouted. John St. is widened from a 30-ft. lane to a 60-ft. street, and Locust St., Eighth St. and Lafayette Ave. are to be widened 14 ft., making them 80-ft. thoroughfares. This gives wide streets along the entrance to the team tracks and the freight-house driveway, and provides for the additional traffic which will use Lafayette Ave., this being

erect a new building according to plans prepared by the city architect and approved by the railway company. The latter will pay $10,000 in addition.

To carry out this development the Great Northern Terminal Co. was organized, its chief engineer being A. H. Hogeland, chief engineer of the Great Northern Ry. H. F. Hamilton, resident engineer of the railway, is in charge of the work. T. D. McMahon, architect for the railway, drew the station plans. W. L. Johnson is contractor for the freight station and also had the contract for clearing the district. This latter was a labor contract and covered selling the houses, wrecking and selling material and clearing up the site, at cost plus ten per cent. Fielding & Shepley were the contractors for the paving. The new freight terminal represents an expenditure of $290,000, while the paving of Pine St. by the city cost $38,000.

Detail-Drawing Method Used For 8800-Ton Steel Ships

Adapted Successfully to Old-Style Ships of Fully Curved Shape—Permits Checking Pieces Before They Leave Shop

BECAUSE a civil engineer does not take naturally to pre-war shipbuilding methods of shaping a wooden templet by the cut-and-try process and then using it as a pattern, the Northwest Steel Co. at Portland, Ore., undertook to develop a better system. Even before the Hog Island plans for structural detailing had been decided upon, the scheme was under consideration at Portland, but, unlike those at Hog Island, the Portland contracts were for the old-style boats with sheer, tumble-home and camber, so that the curved surfaces complicated detail drawings considerably. The plan has worked out well, however, and boats are now being built in part from blueprints instead of by the old method of obtaining the information from the mold-loft floor lines. Only about 70% of the details have been completed, but as soon as the remainder have been worked out the blueprint plan will be used practically to the exclusion of the old method.

About 1400 drawings will be required for the complete set of details. Once these are finished, it is believed, changes which may be required from time to time can be effected to advantage, because studies of adjacent parts can be made before the change is decided upon. Advantages of this kind have already been realized in the economies that became apparent as the details were studied on the drawings with respect to one another. For example, unnecessary three-ply riveting here and there was eliminated as soon as the drawings were compared, although the advantage of this saving had never been so apparent before the drawings were used. The number of different-sized rivets in a single plate has been reduced, and minor details have frequently been simplified, without decreasing strength.

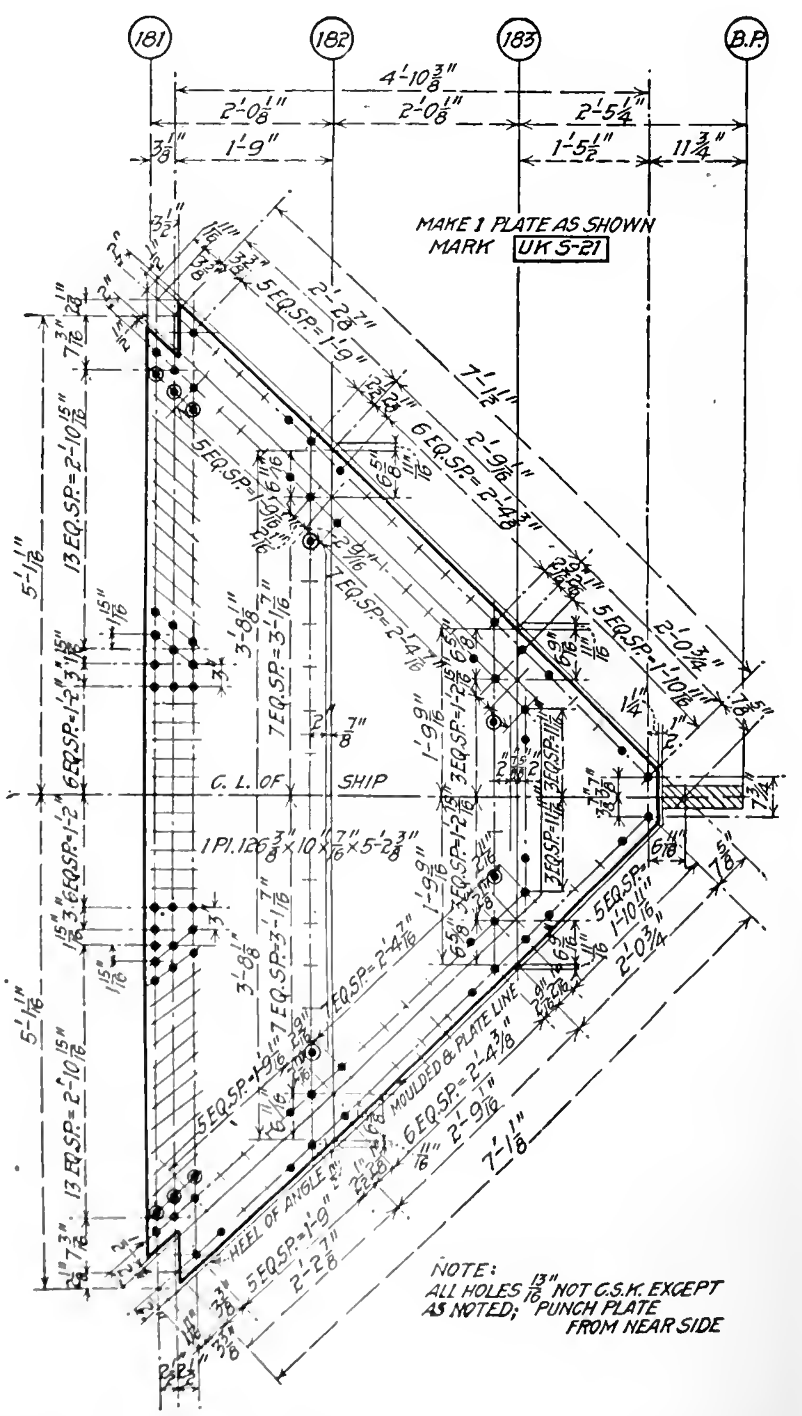
The shop-bill method of ordering shopwork, such as is usual in structural-steel practice, has been introduced in connection with the plan of using detailed drawings. Each shape or plate on which shopwork is required is now listed on a shop bill. These constitute a complete list of material for each ship and afford a means of itemizing material going through the shop and time on each separate job. This plan is commended as a means of avoiding delay and confusion as well as an aid in tracing missing material.

An important change in design was the substitution of a new type of girder. Instead of the built-up girder section, this yard is now making its girders from Bethlehem H12 column sections, with joints on pillars. This saves considerable punching, besides the time and labor required in fabrication.

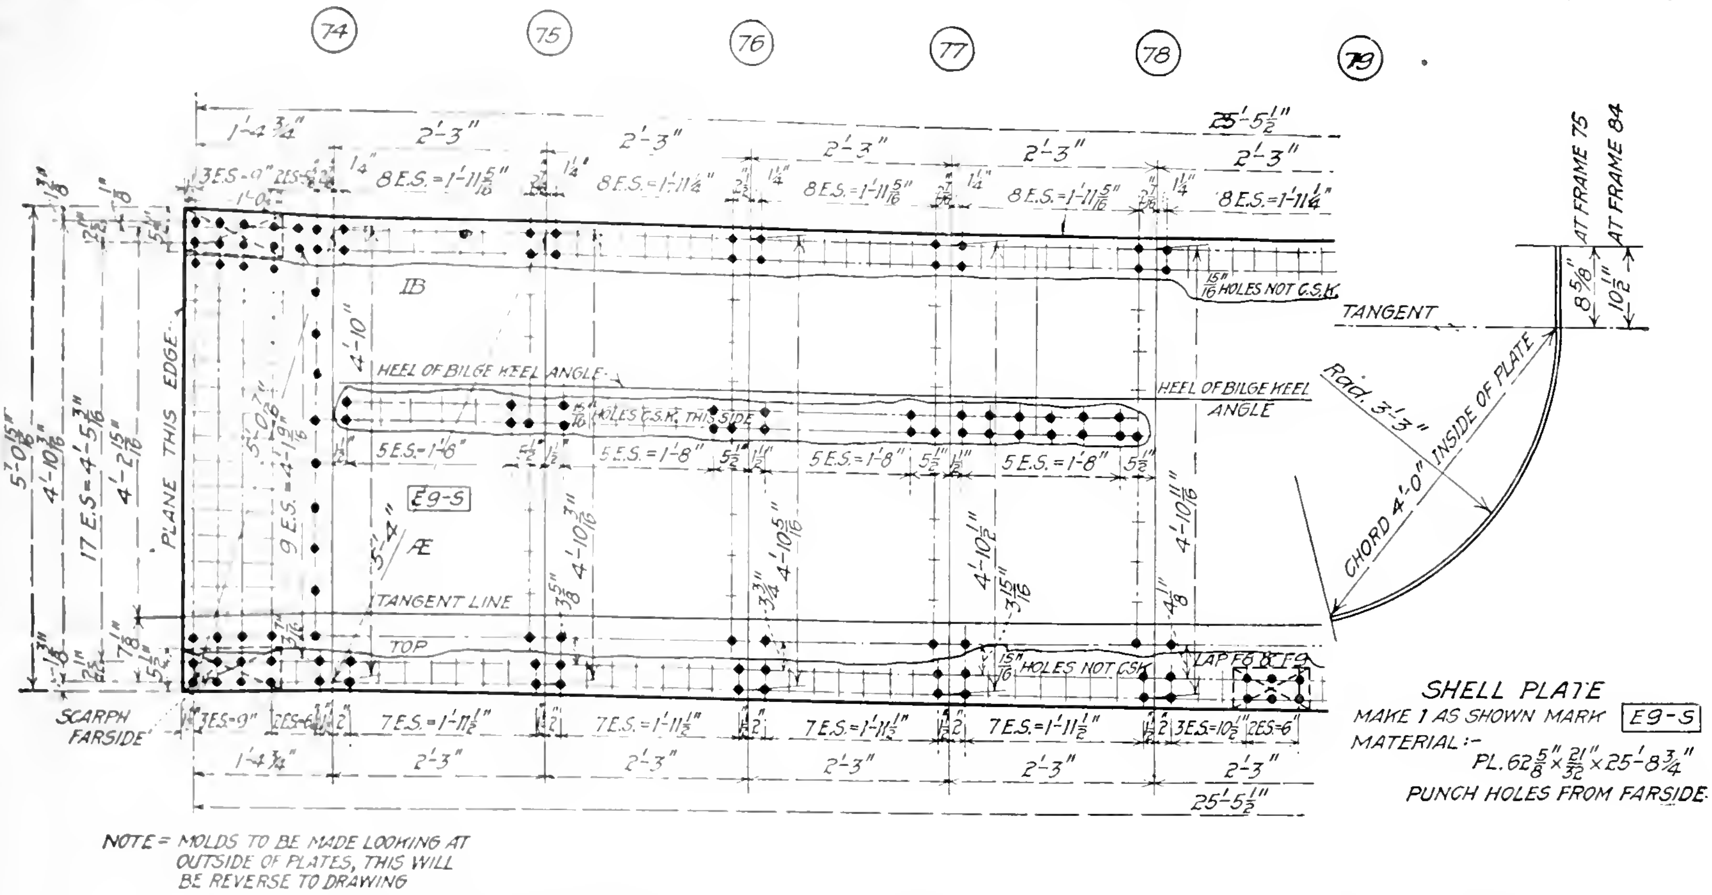
Pre-fabrication is carried out only as far as it can be done conveniently in the shop. No attempt is made to assemble in the yard, where large sections or bulkheads could be laid out. With the blueprint system, it is unnecessary to make special effort on this score, for the foreman can direct the work of assembly in the ship according to drawing. With the old system, only the shipfitter could direct the work, he being the man in whose head the layout was kept clear and from whom detailed instructions were transmitted only orally. With a system where every detail is a matter of record, notable time economies have been made and a structural-steel crew can be very quickly adapted to do this work effectively.

Although large sections are not fabricated in an assembly yard, it is the custom to make up assembled drawings just as is the case with large steel structures. These sectional drawings are issued for the guidance of inspectors and foremen, and are constantly used in checking and making comparisons. For example, an entire bulkhead drawn to small scale on one sheet, and carrying the usual enlarged details worked out for all field joints, is practically all the foreman needs in directing its assembly.

The close supervision possible when details are worked out on the drawing board is a feature that is highly commended. The number of rivets in a gusset plate, for example, is now determined according to exact analysis by a structural detailer, instead of by the man working on the floor of the mold loft. Of course it will always be desirable to make up templets for many parts,



PART OF A TYPICAL DETAIL SHEET—AN UPPER DECK STRINGER PLATE



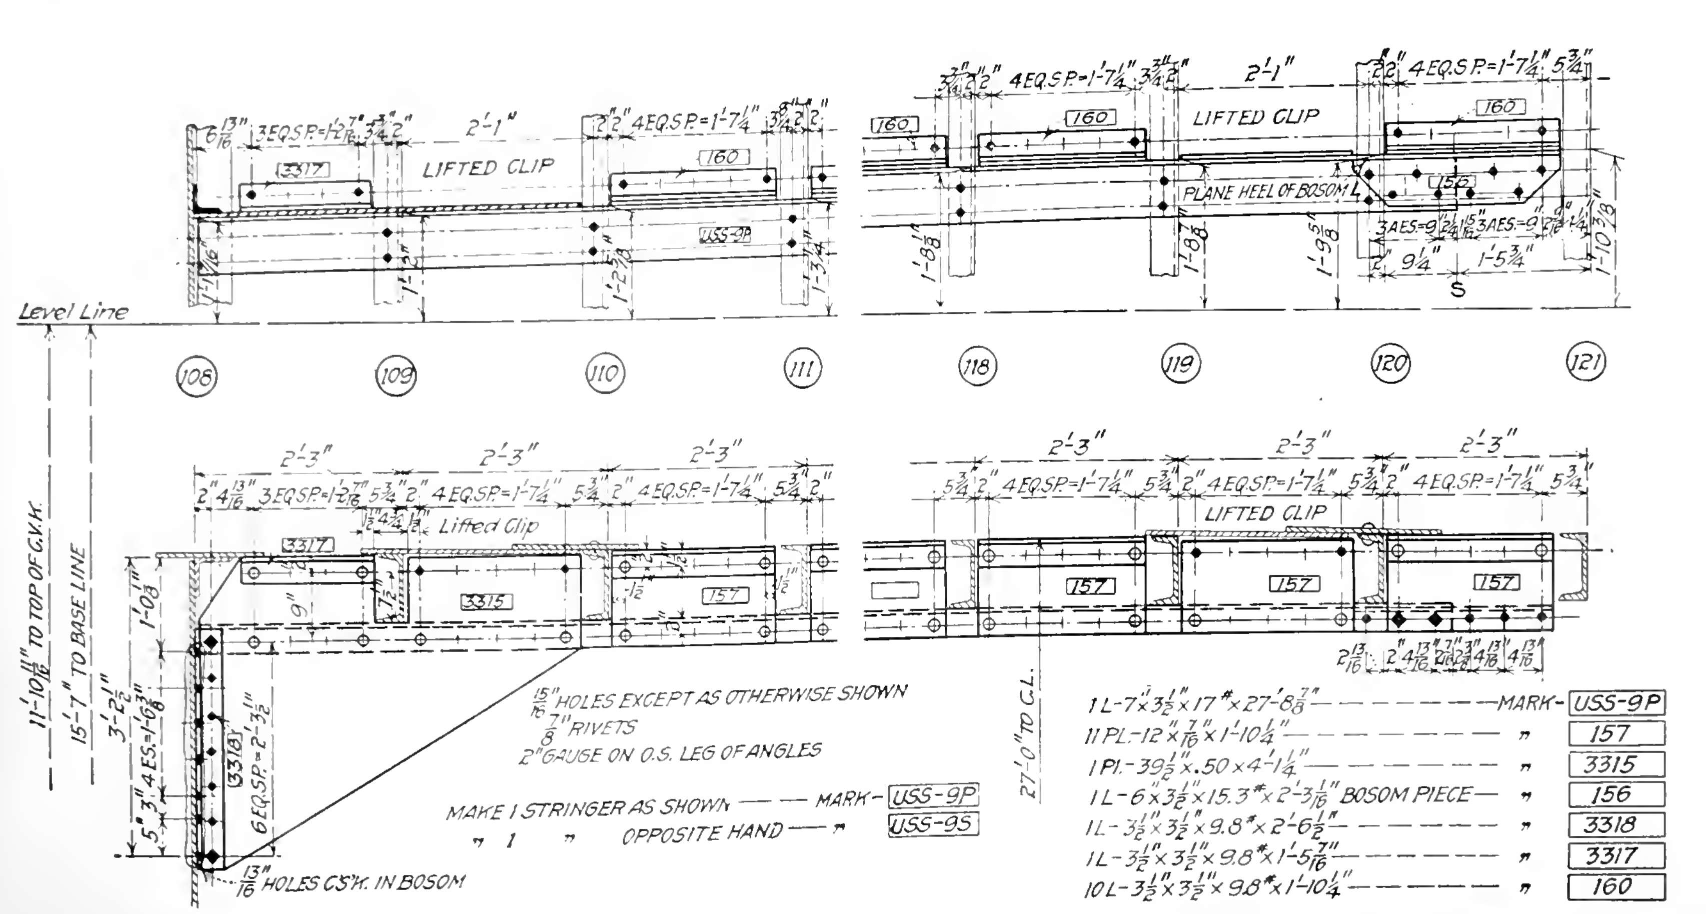
PART OF DRAWING OF A BILGE PLATE; PORT AND STARBOARD PLATES SHOWN ON SAME SHEET

just as it is desirable to keep shipfitters on the assembly work. But templets are now made up according to a blueprint. It is notable that this plan simplifies the problem of obtaining or training men for mold-loft work. Benches have been put in the mold loft on which to make up all but the largest templets. This is believed to have increased the efficiency of the force by about 25 per cent., besides making it much more comfortable for the men.

Perhaps the greatest advantage of all is the use of the blueprints by inspectors in a careful checking of plates and shapes before they leave the shop. This has resulted in the catching of errors before the piece gets into the ship and is, perhaps, partly riveted into its proper place.

With the old system the elaborate markings on the pieces, usually done with a paint brush, could not always be trusted, because there was no means of securing a second check, such as is now made with a blueprint in the hands of an inspector.

Because of the necessity of keeping the yard up to maximum output while the change from templet to blueprint method was made, the transition has had to progress slowly. It has been possible to make steady progress on the detailing and attend to other incidental drafting with a force of about 34 detailers. The most



UPPER SIDE STRINGER REPRESENTED IN TYPICAL STRUCTURAL-DETAIL MANNER; FRAME NUMBERS SHOWN IN CIRCLES

intricate part of the designing has been on those sections of the stern where warped surfaces intersect, known as the "lift plates," the templets for which were formerly made directly on the form of the ship. These have been laid out to scale by developing the surfaces involved. Plates built according to designs so prepared have thus far been satisfactory.

W. H. Cullers is chief engineer and C. D. Merrill is naval architect for the Northwest Steel Co. John Murray is general yard superintendent.

Irrigation Opportunities in Russia Are Great

Chances for Both Public and Private Enterprises—Cotton the Great Crop in Arid Russia but Insufficient for Russian Spindles—Agriculture on Steppes Conducted by Dry-Farming Method

By V. V. Tchikoff

Formerly Chief Engineer of Surveying and Designing Works in the Central Part of Golodnaya Steppe, Turkestan, and in the Lower Part of the Valley of the Dnieper River, Taurida, Russia; now of Berkeley, California.

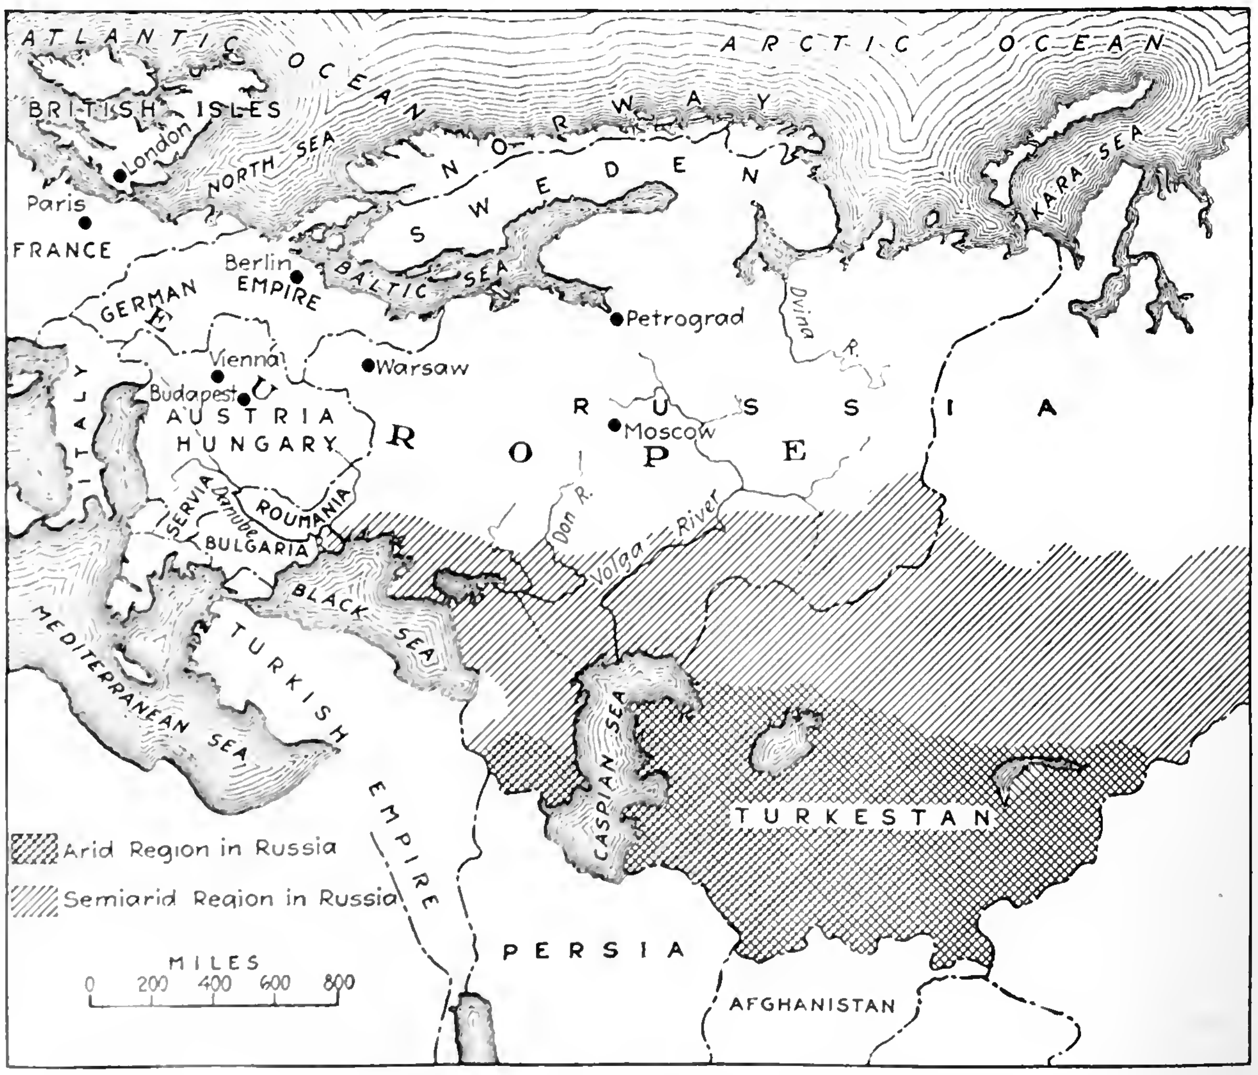
COMPARATIVELY little has been written in English about irrigation in Russia. A few articles in some magazines and a few pages in Dr. Samuel Fortier's work, "Use of Water in Irrigation," give some data. In this article I intend to fill up the gap as much as possible.

Irrigation in Russia is confined mostly to the southern part. Climatically this region may be divided into two parts, the arid and the semi-arid, as shown by the accompanying map.

The arid region, with a semi-tropical climate, comprises Russian Turkestan, including Transcaspia, Bokhara, Khiva and Transcaucasus, where about 10,000,000 acres are irrigated. Since there is very little precipitation during the growing period, agriculture in this region depends entirely on irrigation. The quantity of precipitation is variable, reaching in some places, as in Transcaspia, about 2.5 in. a year, while the evaporation is about 40 times greater. In Tashkent, the capital of Turkestan, the yearly amount of precipitation is comparatively large, averaging 356 mm., reaching 231 mm. in the driest year and 502 mm. in the year of greatest humidity. But during the growing period (from April to October, inclusive) the mean amount of rainfall is 138 mm. Of this amount 86 mm. falls during summer (June, July) and 34 mm. during autumn (August, September and October). Tashkent is situated in latitude 41° 20′, and 1570 ft. above sea level. Its average temperature for the year is 13.4° C. and the average minimum in January —6.2° C. The hottest month is July, with the mean temperature 27.40° C. The length of the irrigation season averages about 200 days, from Mar. 15 or Apr. 1 to October. In the foothills of the mountainous regions of Turkestan agriculture without irrigation is possible but only on a small scale except in the Semiryechenskaja province, where the cereal yield is large. In the arid region, irrigation farming has been practiced for innumerable years in a very primitive way. Ferghana province in Turkestan represents the biggest center, with the largest canals delivering water from the river Syr Daria.

Side by side with the old local systems of irrigation there were started and completed by the old Russian Government some new irrigation projects. Among these may be mentioned the project of the Murgabovo estate, which was built at the expense of the family of the czar for the irrigation of about 100,000 acres. The water was supplied from the Murghab River, on which were constructed a number of reservoirs with earth dams.

Recently there has been finished an irrigation project of 150,000 acres in the so-called Golodnaya (Hunger) steppe in the Syr Daria province in Turkestan, and three projects in Muganskaya, Milskaya and Karabah-



IRRIGATION IN RUSSIA IS PRACTICED MOSTLY IN THE SOUTHERN PARTS

skaya steppes in Transcaucasus. The whole Hunger steppe occupies an area of about 1,250,000 acres; Milskaya, 400,000 and Karabahskaya, 235,000 acres.

During the war there was started an irrigation project in the Semiryechenskaya province as one of the measures for obtaining lands on behalf of the returning soldiers, the heroes of war.

Pumping plants are operated here and there in the valley of Syr Daria, Murghab, Tendgen and other rivers, but more than 99% of the irrigation is from gravity canals. The water for irrigation in the arid region comes from streams which have their sources in the mountains. Because of the melting glaciers and snows, the flood season of most of the rivers occurs in summer, which is very beneficial for irrigation. In most cases the summer supply of small rivers is so small that the natives are able to handle them. But the winter discharge and part of the flood discharge even of the small rivers is left unutilized, and in many cases some reservoirs could be easily built and exploited.

The largest water sources of Turkestan, the rivers Amu Daria and Syr Daria, even without construction of reservoirs, have so much unused water that they would be sufficient to irrigate an additional few millions of acres of very fertile soil.

Bureaucratic Methods Hampered Development

Although surveys were made and data collected during the past decade which should considerably facilitate future irrigation projects, still more data are needed. Bureaucratic methods of conducting work in the public domain have greatly hampered Government and especially private enterprises. Some will remember the trip of A. P. Davis, director and chief engineer of the United States Reclamation Service, to Turkestan to investigate the practicability of constructing a large canal from the river Amu Daria to irrigate the Merv oasis. This enterprise was doomed as untimely. In other districts, as for instance in the Hunger steppe, Ferghana, etc., where the profitableness and usefulness of the erection of new systems could not be doubted at all, the old Russian Government put many obstacles in the way of private enterprises.

With difficulty there was started by private capital during the war the construction of a large project for more than 100,000 acres in the Shirabad valley, Bokhara, utilizing the water of Surkhan River near its junction with the Amu Daria, at the frontier of Afghanistan, near Termes.

Generally speaking, there is still a very small area newly irrigated in Russia, either by the Government or private capital.

Agriculture in the largest part of the arid region of Russia is almost entirely for the production of cotton. These are the only districts in Russia where cotton is cultivated. In the last few years before the war the Russian market supplied only about one-half of the cotton used by the manufacturers in Russia, the other half being imported. In 1912 the Russian mills used about 25,000,000 poods (one pood = 37.12 lb.) of raw cotton, of which was imported through European frontiers about 35% and through Asiatic frontiers about 8%. Cotton imported into Russia through European frontiers in 1912 was 8,986,145 poods, or about 665,000 bales, nearly all American. In 1912 more than 500,000 bales of United States cotton was taken by Russia through the hands of Germany, compared with 112,000 bales imported directly from the United States.

The cultivation of cotton occupies a comparatively large area in the arid region of Russia. In several places of Ferghana province, Turkestan, about 90% of the cultivated area is under cotton. On the average, in the whole Ferghana there was under cotton about one-third of all the irrigated land. The Russian agricultural experiment stations regard as most favorable the rotation with one-third of the land under cotton and one third under alfalfa.

Normally, Russia ranks third among European countries in number of cotton spindles. Most of the mills are in the central or Moscow spinning district.

Irrigated Agriculture Profitable

Agriculture in the arid region is very profitable. In Turkestan, for instance, the rent for the irrigated area is mostly paid from part of the crop. Land rented for cotton cultivation generally brings in Ferghana and Transcaspia half of the crop. The mean yield of raw cotton is about 60 poods per dessiatine, or nearly 800 lb. per acre, reaching as high as 1600 to 2000 lb. The cost of construction of an irrigation project was before the war from 75 to 200 rubles per dessiatine or about $15 to $40 per acre.

Figuring the rent as the sum of half or even a third of the crops at the prices as they stood about before the war, the cost of construction of the irrigation systems could have been paid off in only a few years. The big profit of cotton cultivation brought to the cotton growing region hundreds of enterprising men, ready to irrigate the desert land.

The new cultivation of large projects, say about 100,000 acres, would present an altogether different problem. The main problem in the creation of new irrigation systems lies not in the engineering difficulties, but in the selection of settlers and in the successful settling of the land in the shortest possible time.

The conditions of Russia in this respect before the revolution were as follows: There existed in Russia a constant migration of landless peasants. Although Turkestan and Transcaucasus were temporarily closed to settlers, the wave of migration reached even these regions and formed there some so-called "self-willed" villages. Moreover, there is in the oases of the arid region a native population so dense and land hungry, many of them being tenant farmers, that they form quite a shifting element, always ready for settlement of new irrigation projects.

Should the primitive methods of cultivation with native implements be supplanted by modern agricultural machinery, it would also help the exploitation of the new irrigation projects.

As a result of the Russian revolution the land resources of the Russian peasants will probably be improved, so that the emigration to Turkestan should be lessened, but this may influence only the size of the area to be newly irrigated.

In view of the fact that the demand for cotton is great and that the possible supply of unutilized water and land is abundant, irrigation in Turkestan and other

places of the arid region should be one of the first big problems of New Russia.

The importance of irrigation in the semi-arid region presents a problem of an altogether different character. This region comprises the southern and southeastern part of European Russia, the steppe provinces and western Siberia. The unpropitious conditions for farming in this vast region are mostly due to lack of precipitation as well as to its great fluctuation. The unfavorable periodic distribution of rain was disastrous to farming in some provinces, and the old Russian Governmnet often had to undertake public works and other measures of relieving the population stricken by crop failures. The suffering is especially acute in a whole row of provinces on the middle and lower part of the River Volga.

During the present war large sums of money were appropriated for irrigation and similar works in the above mentioned provinces; investigations were undertaken with the same purpose in southern Russia, north Caucasus and in some places in Siberia.

Among the unfavorable conditions for the development of irrigation projects in this region is the difficulty of getting water on to the land. Most of the rivers have eroded themselves deeply into the ground, and utilization of their water would require lifting to a great height. The underground waters are deep seated. The little streams of the steppe, being fed by precipitation, mostly bring their water in the spring during the thawing of snow. Reservoir construction would insure water for only a small per cent of the area. Only in the delta and in the overflowed land of some big southern rivers—Dnieper, Don, Kuban, Terek, Dniester, part of the Volga—would comparatively large irrigation projects be practicable, and these would involve the construction of levees.

Generally speaking, the irrigated area in the semi-arid region will appear as rare spots in the vast steppes, where agriculture is conducted under the method of dry farming. There are at present about ten such irrigated plots. In the semi-arid region of Russia, and especially in some parts of the steppe provinces and western Siberia, the supply of water for domestic purposes is of the first importance. There is a great similarity between the semi-arid region of Russia and that of the United States and Canada. The steppe region in Russia equals the prairie region of North America.

Fruit Culture in Russia

Crimea, Bessarabia, Caucasus and Turkestan yield the biggest supply of fruit. Apricots, peaches, quinces, pomegranates, figs and almonds grow in the open air in these provinces. In some places of Transcaucasus even oranges and lemons grow.

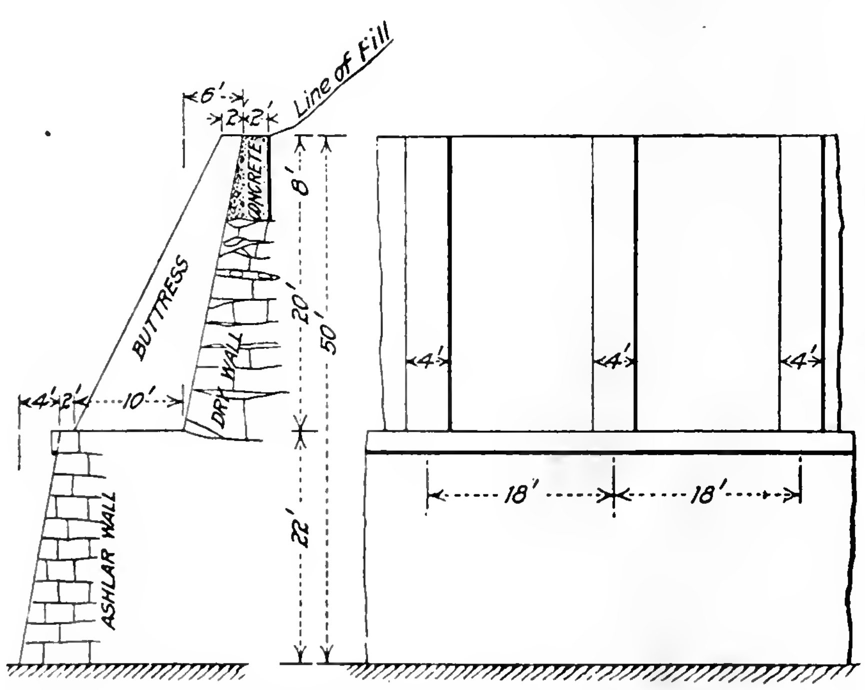
The Crimea is the chief growing center. Crimea bears the same relation to the rest of Russia as Southern California has for the United States. In the article of D. Kotcherin, "Russian Engineers Make Intensive Hydrometric Survey in Crimean Upland," in *Engineering News-Record* of Apr. 4, 1918, p. 657, are given some data on irrigation in the Crimea. The streams, with few exceptions, run dry two or three days after a rainstorm. The fluctuation of the discharges is very large. The slope of the streams is so great that the valuable agricultural lands are often destroyed by storm water. The sources of irrigation are small and the water values very high. What is necessary for Crimea is a proper storage of water, an increase of the use of underground water and the economical methods of irrigation followed in southern California.

Holding a Bulging Retaining Wall With Buttresses

High Fill of Slippery Material Forces Out Dry Wall—Grouting and Buttresses Solve Difficulty Satisfactorily

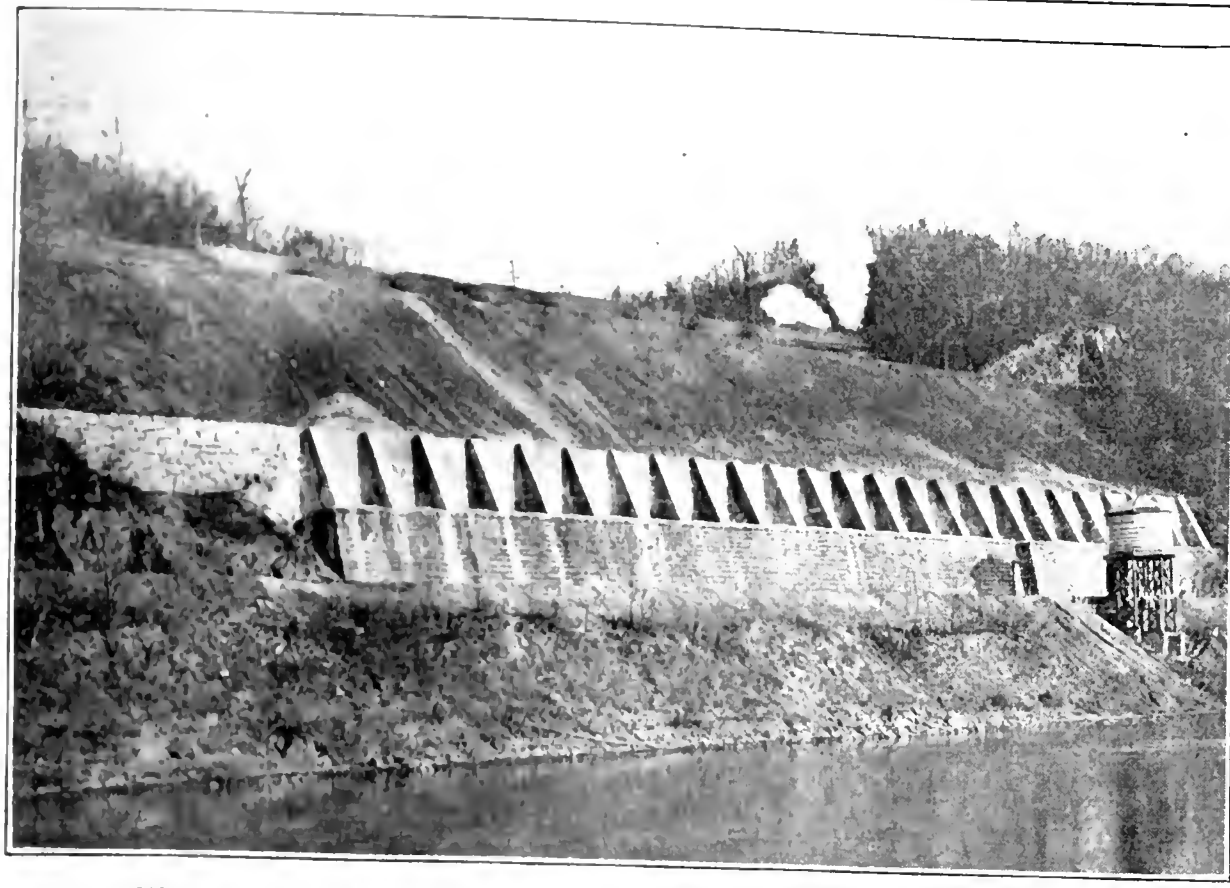
IN BUILDING the low-grade freight line of the Pennsylvania R.R. some years ago from Columbia, Penn., to Trenton, N. J., a high fill was made across a narrow ravine on the bank of the Susquehanna River near Safe Harbor, Penn. This fill was made largely of cinders, and is about 550 ft. long and 130 ft. high. At the foot of the fill runs the single-track line of the Maryland Division, about 40 ft. above the Susquehanna River.

In order that the fill might not encroach on the track at the lower level, a masonry retaining wall was built, 24 ft. high, with a face batter of 4 ft. This wall proved strong enough to stand the outward pressure but not high enough to retain the slippery cinders. Some years later, therefore, a dry masonry wall was built on top of the lower retaining wall. This dry wall was started 12 ft. back of the top of the lower wall and was carried up to a height of 22 ft. Still later a wooden cribwork 8 ft. high was placed on top of the dry wall.



CROSS-SECTION AND FRONT ELEVATION OF RETAINING WALLS AND BUTTRESSES

In November, 1917, it was found that the dry wall was bulging from the pressure of the fill behind it, and it was deemed necessary to undertake repairs to make the roadbed safe. Several plans were considered, among others the construction of a concrete wall 12 ft. high placed on top of the lower masonry wall, to hold the dry masonry from further movement. Another proposal was to place a form in front of the dry wall and one foot away from it, and fill the space between with



VIEW TAKEN AFTER DRY WALL WAS GROUTED AND BUTTRESSES WERE BUILT

concrete, which would of course work back more or less into the interstices of the dry wall.

A plan was finally suggested and carried out under contract by Harold P. Brown, of New York City, involving the strengthening of the bulging dry wall with a series of buttresses, each 4 ft. wide and 40 ft. high, placed 18 ft. apart. Between these buttresses Mr. Brown proposed to fill the dry wall with concrete, and then face the surface with his concrete atomizer. The buttresses were to be connected at the top by a concrete wall 8 ft. high built on top of the dry wall.

It was necessary to carry on this work, however, without interrupting the traffic on the single-track line of the Maryland division which ran close to the foot of the lower retaining wall. The materials for the work were brought on this line. A side track was constructed outside the main line and parallel with the top of the retaining wall. A line of rail was laid along the top of the retaining wall and a traveling crane was constructed with its lower leg supported by a flat-car on the siding and its upper arm reaching across and traveling on the rail laid on top of the retaining wall 24 ft. above. On one end of the flat-car a tower was built, and a timber truss bridge reached from the top of the tower to the retaining wall.

The wheels which carried the end of the bridge resting on the wall had long axles, loose in their bearings, so that accurate lining up of the side track with the rail on top of the wall was not necessary.

On the end of the bridge nearest the wall was set a light jib crane and also an inclined frame through whose uprights timbers could be shoved forward horizontally as far as the face of the dry wall to support scaffolding at any height.

On the end of the flat-car opposite the tower was placed a 45-hp. boiler, and between the two was a double-drum hoist. A Brown concrete mixer and steam atomizer for delivering concrete through hose was located at the bottom of the tower. On the level above was placed a measuring box discharging the concrete materials into the mixer below, and above the mixing box were bins with under-cut gates for sand and gravel. These materials were brought in by rail and were unloaded and placed in the bins by a small jib crane at the corner of the tower. Work was begun at the sixth panel, where the dry wall showed the greatest bulging and apparent danger of sliding. In filling the first panel a very large quantity of concrete was used, and the material appeared at openings in the dry masonry wall on a frontage of 90 ft. and also showed up nearly 90 ft. back of the front line of the wall in a culvert which extends underneath the fill. The jib crane on the traveling bridge proved very convenient in setting and placing the forms for the buttresses, as well as in raising the grout and the concrete.

To provide an added factor of safety against any movement of the completed structure under the pressure of the fill behind it, steel tension members cut from old car truss-rods rescued from the scrap pile were embedded in the heel of the buttresses, the lower end being carried down to a secure anchorage. The entire work of buttressing the wall was carried on to completion without interfering in any way with train movements.

Mr. Brown and his associates designed and supervised the work, the railway company furnishing the

BULGING DRY MASONRY WALL UNDER A HIGH FILL

TRAVELING TOWER-CRANE SPANNING MAIN-LINE RAILWAY

labor and materials; the whole was under the direction of Elmer Irving, division engineer of the Pennsylvania R.R. at Harrisburg, Penn.

Chicago Plan Commission Proposes Great Improvement Scheme

A COMPREHENSIVE program for the development of the City of Chicago, as a means of meeting the problems of the reconstruction period, has been submitted to the mayor and the city council by the Chicago Plan Commission. The individual projects are not new and some are already under way, but the program lists them all as component parts of one great scheme of improvement. The projects in the downtown portion of the city are shown on the accompanying map. The projects which are under construction and should be pushed vigorously, according to this program, are as follows: Widening Twelfth St. to form a new thoroughfare between the west side and the lake front; widening and extending Michigan Ave. to form a direct connection between the North Side and South Side boulevards, including a double-deck bridge over the river; revision of the West Side terminals, with construction of the new union station and the widening and double-decking of Canal St. from Twelfth St. north to the river, which is to be crossed by a double-deck bridge at Kinzie Street.

Completion of the outer circle boulevard from the lake, on the North Side, along the Des Plaines River and through the forest preserves. Only two miles of this remain to be formed by the opening of Rogers Avenue.

The projects already formulated, but not yet commenced or officially adopted, include the following:

Revision of the Illinois Central R.R. terminals, with a new passenger station, electric operation, track elevation and harbor and park development along the shore. All this is covered in an ordinance submitted recently by the Railway Terminal Commission.

Straightening the south branch of the Chicago River to improve the street layout and give opportunities for property development.

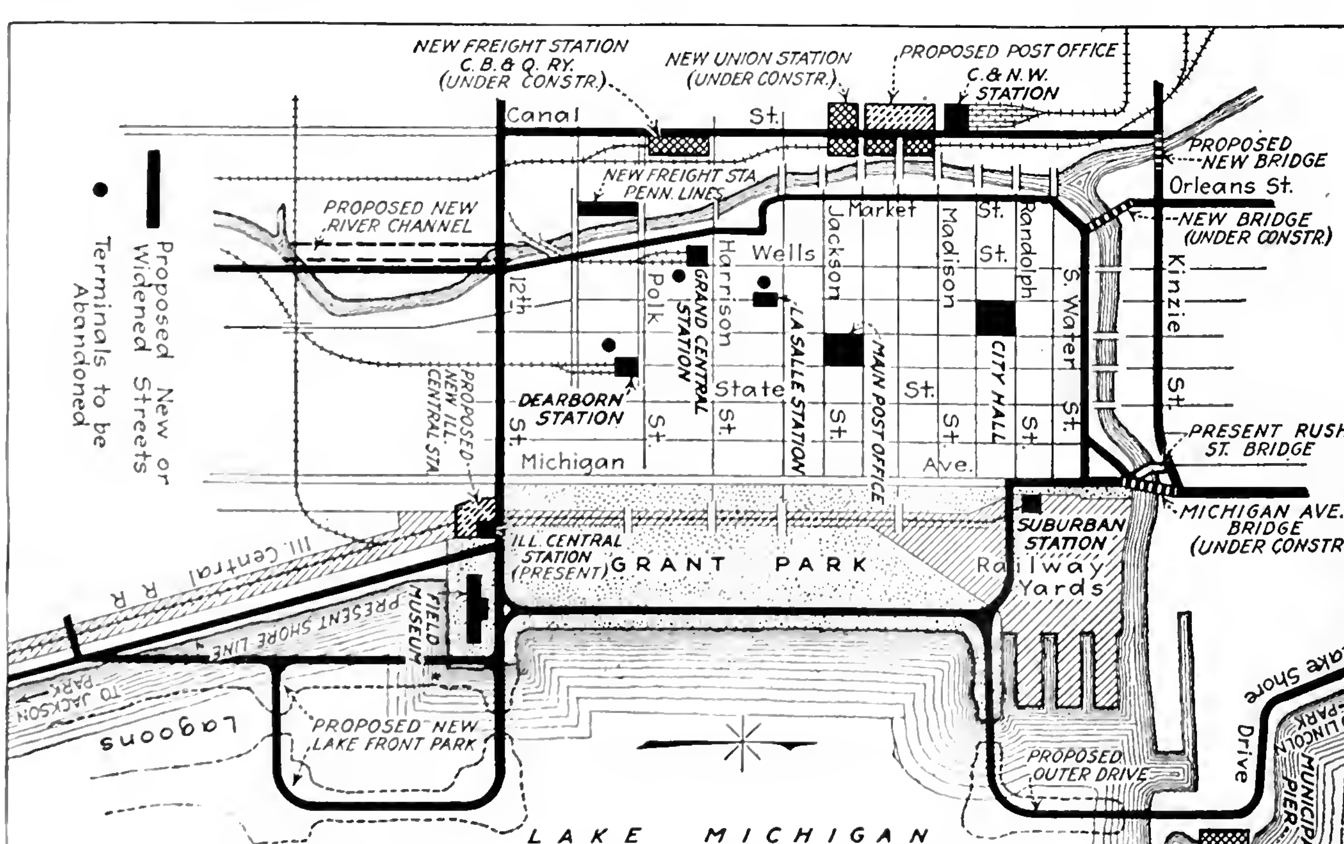
The removal of three South Side passenger terminals to the new Illinois Central terminal on the lake front and the revision of freight terminals, thus opening a number of important streets now closed by railway yards and tracks, and releasing valuable property now occupied by freight yards.

Extending Ogden Ave. to form a new diagonal thoroughfare between the northeast and southwest districts, thus diverting considerable traffic from the congested loop district and opening up a new industrial district.

Widening Western Ave. and widening and extending Ashland Ave. and Robey St. to form two continuous thoroughfares. These are three north and south streets on the West Side of the city.

Improving So. Water St., which is now practically a produce and poultry market, and reclaiming it for public use. This includes a double-deck construction.

Building an outer drive along the lake front to connect the north and south parks, and thus afford an independent route for the use of pleasure traffic, also boulevards along the right-of-way of the Drainage Canal.



SOME DOWNTOWN IMPROVEMENTS ADVOCATED BY CHICAGO PLAN COMMISSION

The construction of a new West Side postoffice, adjacent to the West Side railway terminals, where 62% of the city's mail is handled.

Other matters advocated are the completion of the city's bridge program; the settlement of the rapid-transit controversy; the development of the forest reserves, and the construction of highways connecting Chicago with the good-roads system of the state. The Chicago Plan Commission also indorses a new city charter, the study of the zoning and housing problems, and passage of an excess condemnation act to eliminate objections to the present method of making public improvements.

Appropriations are recommended for preliminary work on the Ogden Ave., Western Ave., Ashland Ave., Robey St. and So. Water St. improvements noted above.

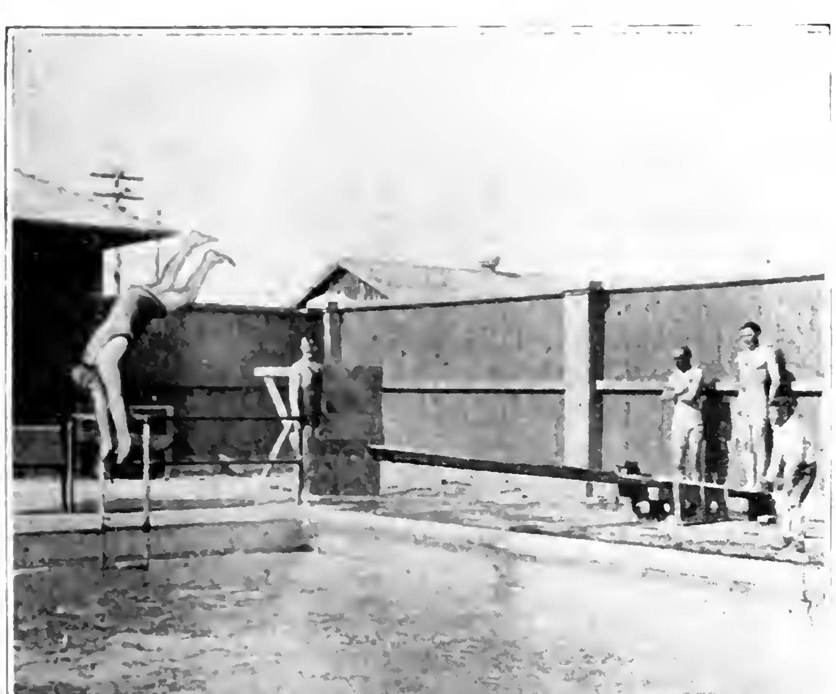
Reinforced-Concrete Swimming Tank Was Carefully Designed

Fort Bliss Pool Has Combined Wave Break and Scum Gutter—Adjustable Springboard Holder—Form Details

By R. McC. Beanfield
Captain of Engineers, United States Army, Camp A. A. Humphreys, Virginia

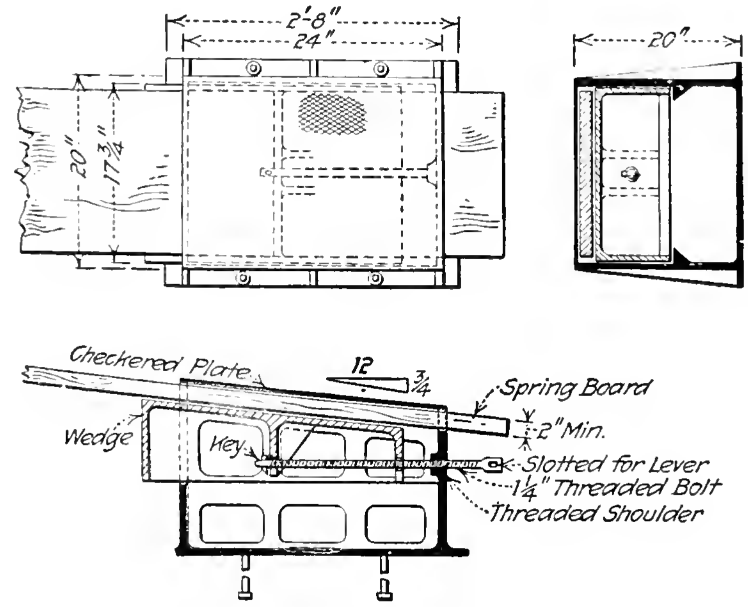
IN THE design and construction of the reinforced-concrete swimming tank at Fort Bliss, Texas, many interesting details were worked out which may contain suggestions for engineers contemplating the design of a swimming pool.

For a tank large enough to meet the requirements of this post, considerable study had to be given to the economics of the problem, as the money available, do-



DIVING FROM ADJUSTABLE SPRING BOARD

nated by the War Camp Service Board of El Paso, was limited to $2500. The tank was built with skilled labor—such as carpenters, men handling the concrete mixer and cement finishers—furnished mostly by the battalion of the 8th Engineers (Mounted). This enabled the engineer troops to obtain practical instruction in work closely related to their future duties—the building of concrete dugouts, gun emplacements, and the like. For common labor prisoners from the Fort Bliss prison stockade were used. A ½-yd. concrete mixer and four concrete buggies were lent by an El Paso contractor. Sand was obtained close to the site of the tank, and was screened and loaded by prisoners into Army wagons. Trap rock for concrete was hauled to the job by Government auto trucks. The $2500 donation, therefore,



SPECIAL CASTING FOR ADJUSTABLE SPRING BOARD

was utilized only for the purchasing of materials required in the construction of the tank. These materials were supplied at cost by El Paso merchants.

From previous experience in the design of swimming tanks, the writer based the present one on the following fundamental requirements: (1) Locate below the natural ground the level part of the tank and use the excavated material later as fill around the walls of the tank above the natural ground level—this economizes in excavation and grading; (2) cast each side of the tank as a monolithic unit up to the water line designed as a cantilever wall—this results in a minimum of construction joints and the most economic wall section; (3) cast the bottom, or floor, of the tank as a monolithic unit, independent of the walls and wall footings—this tends to eliminate cracks due to unequal settlement and shrinkage; (4) locate expansion joints of the diaphragm type in each corner of the tank, to facilitate the construction by reducing the joints to a minimum; (5) install a combination scum gutter, overflow and wave break, of concrete cast with the wall; (6) construct the tank of proper shape and size to hold swimming contests regulated according to the National Amateur Athletic Association rules.

The tank is 40 x 100 ft. in plan, with a maximum water depth of about 9 ft., a water depth of about 7 ft. at the diving end and of some 4 ft. at the other end. For future work the writer suggests a 6-ft. water depth at the diving end, with a maximum depth of 8 to 9 ft., some 16 to 25 ft. from that end wall.

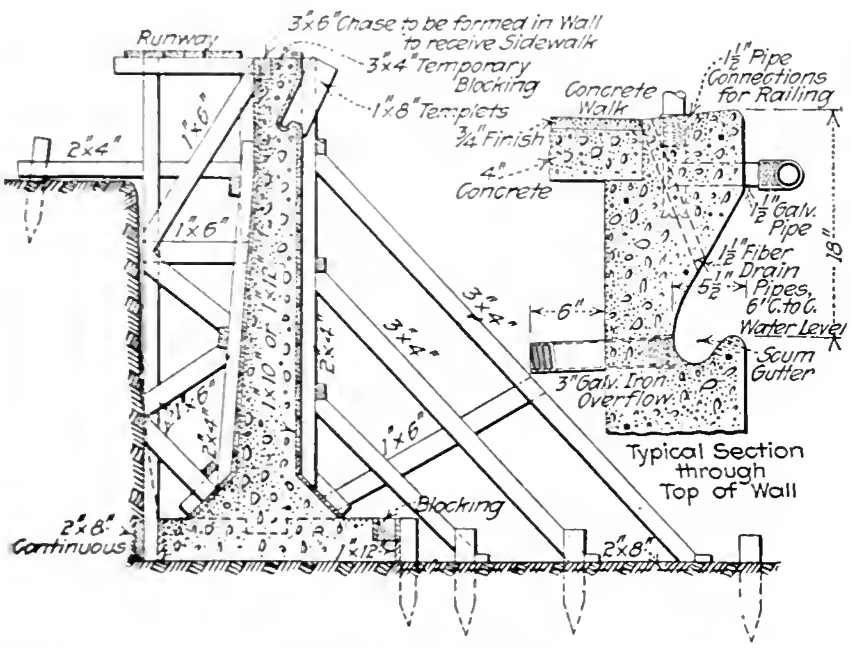
The site on which the tank was located had a surface stratum of 4 to 5 ft. of caliche, under which a deep layer of sand was found. The excavation was started by a rooter plow, which broke the caliche sufficiently to permit its excavation with fresnos and slip scrapers.

The accompanying sketch of the wall form shows a very efficient method of exterior bracing.

The concrete was proportioned for maximum density on the basis of a 1 to 6 mix. No integral waterproofing was used. The consistency of the concrete was

gaged by the visual test; that is, by keeping the stone always in suspension in the mixture. Some of the concrete was mixed by hand for practical instruction. Each side of the tank was poured continuously until completed. The walls could have been poured up to the water line in one operation, which would have facilitated the work, as the scum gutter forms were somewhat difficult to strip in order to avoid breaking of the nosing of the scum gutter. Before the 6-in. floor of the tank was poured, the sand subgrade was well compacted with water and tamped. The 6-in. base was poured continuously until completed. Negative moment was provided for by bending the slab reinforcement up at all supports.

The scum gutter was designed to serve both as a wave break and as an overflow and drain to collect floating



WALL FORM BRACING AND DETAIL OF SCUM GUTTER

débris and scum. The water draining into the scum gutter flows through 3-in. drain pipes to a drop manhole in which is set an 8-in. gate valve, with an extension key, which controls the discharge line. An open invert in the concrete base of the manhole connects the gate valve to an 8-in. terra-cotta pipe line 250 ft. long, which is connected with one of the manholes of the Fort Bliss sewer system. The invert eliminates a rather difficult joint between the screw flange of the gate valve and the terra-cotta drain pipe. By reason of the open invert, a leak in the gate valve can be easily seen. The drains lead from the scum gutter and discharge directly into the manhole, eliminating connections to the discharge pipe.

Often the rungs of ladders for use in swimming tanks are made of small diameter bar iron or other material which tends to hurt the feet. The ladders for the Fort Bliss tank were entirely constructed of 1½-in. galvanized-iron pipe. The fittings for the ladder and part of the fittings for the hand rails were reamed to permit the pipe to pass through them. The fittings were afterward bored for setting countersunk rivets, which were filed smooth with the pipe surface.

Expansion joints were located at the four corners of the tank. The joint was made with two 24-gage galvanized iron diaphragms, notched for bond, with hot California asphalt poured between the diaphragms. The joints were carried up only to the top of the scum gutter. A plain asphalt paper construction joint was used from the scum gutter to the top of the tank. A board covered with asphalt paper was used to form the joint while the concrete was being poured. After the concrete had set a little the joint board was carefully pulled from the joint.

A two-ply, 14-lb. felt, mopped in hot asphalt, was laid on top of the 6-in. concrete floor to serve as a waterproofing membrane. A 3-in. 1 : 6 mix concrete slab, divided into 10-ft. squares by asphalt joints, was placed over the membrane coat to protect it.

A 5-in. 1 : 7½ mix concrete floor subdivided by two marginal brick joints was placed around the entire tank. The brick joints were placed as planes of weakness, separating the greater part of the slab on the fill from those parts bearing on the walls of the tank and on the curb beam between the columns, thus avoiding unsightly cracks should the fill settle. The brick were especially chosen for their varying colors. Between the ¾-in. deep V-grooved joints the slab received a troweled finish followed by a toothed roller which neatly roughs the smooth finish, preventing slipping.

A special casting designed by the writer was used as a spring-board holder. This holder contains a cast wedge, adjusted by means of a screw bolt turning in a threaded shoulder cast with the exterior frame, that clamps the spring board at any desired length, thus varying the elasticity of the board as well as increasing its life.

The swimming tank, in addition to its use for bathing, is available as the source of an auxiliary water-supply for fire fighting, an important feature in isolated Army posts. The water in the tank is sterilized with hyperchlorite.

The work was done under the direction of Col. V. L. Peterson, commanding the 8th Engineers (Mounted). The writer designed the tank and supervised its construction.

Direct Microscopic Count of Sewage Bacteria

In studying, by the usual method, the agglutination of bacteria and attempts to separate masses of these organisms before plating, Milton F. Stein, Chicago, investigated the direct microscopic counting method, using a blood-counting cell. His results were described in the course of a recent paper read before the sanitary engineering section of the American Public Health Association. In one instance, where the average of 10 tests by the usual method gave 3,950,000 per cubic centimeter, the direct count gave 70,720,000 as the average of 10 counts made by two observers. Mr. Stein attempted, by shaking for various periods, to separate bacteria clinging in bunches to particles of foreign matter. For the 10-min. period the increase was 67% over the usual method. He concludes that the number developed by plating is not over 10% of the total number present. A review of the governing conditions indicates that no constant proportion can exist, that under unusual conditions the standard method gives distorted results, and that for special work modifications to reduce these distortions seem advisable. The full paper, which is a mathematical discussion of chances of error in water and sewage bacterial counts, was published in the November *American Journal of Public Health.*

Medical Inspection at Miami Camps Checks Influenza

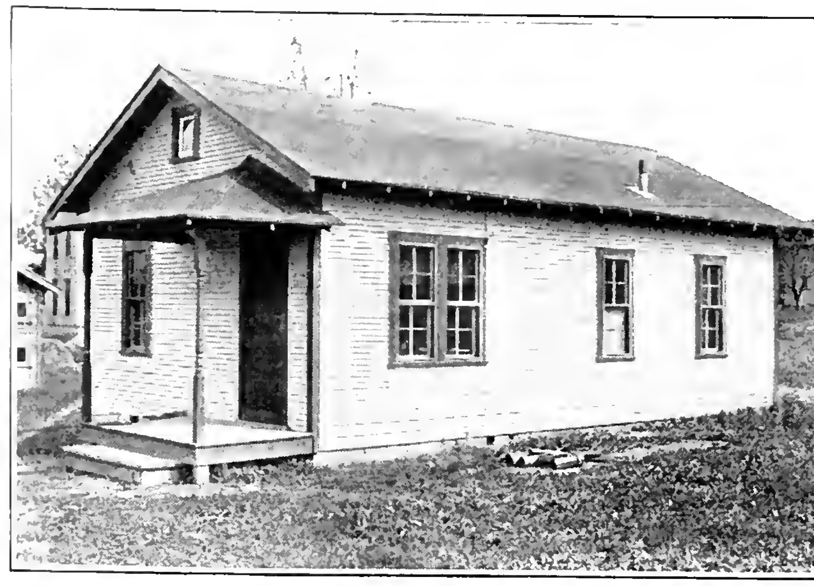
First-Aid Hospitals, Local Doctors and Chief District Physician Held Back Epidemic at Five Conservancy Dams

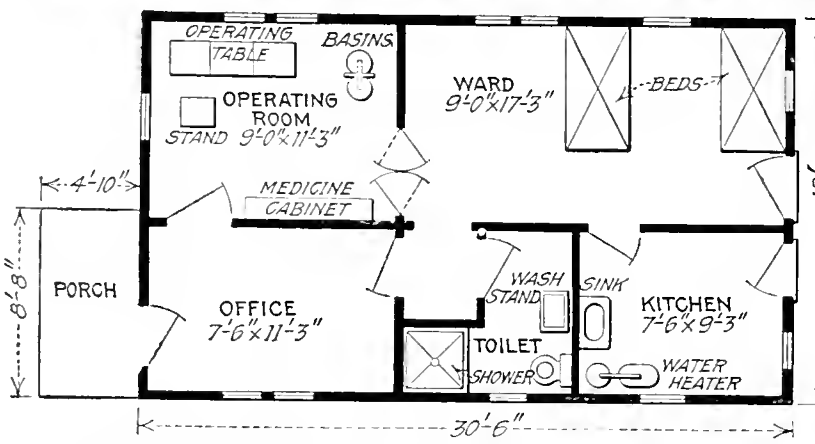
MEDICAL inspection reduced to barely a score of mild cases sickness from influenza at the five dam-construction camps, housing some 400 persons each, of the Miami Valley flood-protection works. The methods, somewhat intensified for the period of the epidemic, were those regularly provided for protecting health and caring for injuries on this work. They comprise attendance of a physician and provision of a small first-aid hospital at each camp and, if the cases are serious, removal to city hospitals.

Local physicians at the camps and a chief physician at headquarters compose the medical staff. The chief physician gives all his time; the local physicians, one for each camp, serve only on call, except at the Huffman Dam, where a doctor gives all his time to the camp work. The procedure is about as follows: The camp overseer or superintendent is held responsible for first aid and for calling the local physicians and notifying the chief physician. If the case is serious and the worker has no home of his own, or if he requires better care than is practicable at home, he is sent to the city hospital. The Conservancy District assumes no financial responsibility for cases of sickness, except that the chief physician on his regular inspection trips visits the sick person without charge. For special visits payment is asked.

At each camp a hospital building is provided and equipped for first-aid work and as an office for the physician when he is at camp. All the essential features of these field hospitals are indicated by the illustrations. So far during the work no serious accidents have occurred and sickness has been rare. The medical staff and the sanitary inspectors proceed always on the theory that prevention is better than cure.

Direction of camp hygiene is in the hands of Dr. W.





FIVE CAMP HOSPITALS GIVE FIRST AID TO EMPLOYEES

M. Smalley for the Miami Conservancy District. Arthur E. Morgan as chief engineer, Charles H. Paul as assistant chief engineer, and C. H. Locher as construction manager for the district supervise all activities.

At the outbreak of the influenza epidemic, the district camp inspector and the chief physician immediately took steps to safeguard the camps. It was arranged that the resident physician at the Huffman Dam should visit the cottages there and at the Taylorsville Dam; that the chief physician should visit the camps at Englewood and Germantown, and that a local physician should similarly care for the camp at Lockington. These visits were much more than perfunctory. The physicians interviewed the workmen and their families, gave instructions regarding the nature of the disease, the symptoms denoting it and the steps to be taken, emphasizing the necessity of prompt action and of calling a doctor at once. In addition, the district printed a circular which was distributed through all the camps and which was in effect a repetition of the instructions given orally by the physicians. Only a few scattered cases of influenza developed. At Englewood there were seven or eight cases, at Huffman three or four, at Germantown five or six, and at Taylorsville only one or two. Only two cases of the disease, however, could be classed as severe.

OPERATING ROOM IS EQUIPPED WITH ALL APPARATUS REQUIRED FOR FIRST-AID

Society Service

A Section Dealing with the Results of Teamwork by Technical Men

Growth Chart on Postcard Boosts Society Membership

In a new-member campaign being pushed by the Iowa Engineering Society, postcards the size of a blotter are distributed, showing a chart of the growth, since the organization started 30 years ago with 40 members, to the present membership of 220. At the side of the chart are these "selling" arguments: "Is it worth while to broaden your acquaintance, to contribute your share to the progress of the engineering profession, and to serve the highest interests of state and nation in whole-hearted coöperation with your professional brothers?"

A census of all engineers in Iowa is proposed, the state to be districted to correspond with a membership of a special committee which represents the various sections and organizations of the state. If possible, a permanent system is to be developed to keep the census up to date. Based upon this census, local clubs can be formed and affiliated with the state society.

Duluth Engineers Propose United Society for Nontechnical Work

A combined organization, formed by the coöperation of all of the recognized societies, to supplement, but not supplant, the latter, is a step proposed by the Duluth Engineers' Club, which has appointed a committee representing the four national societies of civil, mechanical, electrical and mining engineers and the chemical society. Technical work would be carried on by the separate societies as at present, the new organization dealing with such matters as the status of the engineer, his relation to the public, ethics, employment and publicity. According to a circular issued by the committee, the new combination must not destroy the identity of the present societies; it must take their good points, add what may be desirable and eliminate any undesirable features.

Iowa Society Will Promote License Bill and Encourage Affiliations

At a recent meeting of the executive committee of the Iowa Engineering Society, it was decided to present to the next legislature a bill for the licensing of engineers. It was considered desirable to carry out the plan previously developed for this end as the war is practically finished and the reconstruction period is at hand. It was decided also to proceed with the plans for forming Iowa sections of the national societies of civil, mechanical and electrical engineers, with a view to affiliating these with the Iowa Engineering Society. In fact, it is hoped to affiliate all the engineering societies of the state in one united state society, with the idea that if other states take similar action it will be possible eventually to form one national united engineering society, comprising nearly all the nation's engineers.

Local Society Admits National Society Members Without Fee

For some time the Engineers' Society of Western Pennsylvania has been omitting initiation fees of candidates who were already members of the four Founder societies. In addition, on Oct. 1, the Board of Direction approved recommendations of the membership committee that members of the American Chemical Society be admitted as associates on the same basis. Following this order, the question of organizing a chemical section was taken up. The proposition of adding still further to the accredited list of societies whose members would be exempt from initiation fees was discussed with the request that the Society for the Promotion of Engineering Education be considered by the membership committee.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

C. L. Christensen Replies to Dr. Steinman on Equivalent Uniform Loads

Sir—Permit me to make some few concluding remarks in answer to Dr. D. B. Steinman, in your issue of Dec. 26, 1918, p. 1193.

1. The uniform load method proposed by me is not intended for cases where Dr. Steinman's carefully worked out values can be used, but for cases in which they cannot be used. I stated this clearly in my preceding letter, but Dr. Steinman seems to lose sight of it.

2. The error made in using Dr. Steinman's curves for reversal is not small. In a design for a 640-ft. two-hinged arch it amounted to about 35% in the reversal live-load stress, and more than 10% in the resulting design stress for the diagonals adjacent to the center vertical. In a 252-ft. simple through truss span the inaccuracy in the reversal stresses for the diagonals near the center was about 25%, but in the resulting design stress it was only 5 per cent.

There is nothing far-fetched or unusual in computing the actually occurring reversal stress, since the A. R. E. A. specifications, as well as the New York Central R.R. specifications call for this. Dr. J. A. L. Waddell makes a clear distinction between reversal occurring during the passage of the train and reversal occurring later for a different live load, and calls for a higher percentage of reversal to be used in the former case.

It may have occurred to many bridge designers that the requirements in case of reversal are rather severe for long-span bridges, since it may take more than 5 sec. to make the reversal. There is then so much more reason for being exact and not extravagant in adhering to the specifications; otherwise the result will be a freakish detail design for the panel point and a waste of material and rivets.

3. Dr. Steinman states that by applying the uniform load method proposed by me the amount of error found was from 2% to 5%. I believe that an error of 5%

can only be found in case the loading is used to find the end reaction for a 200- to 250-ft. span. In case of finding the end reaction, the pilot wheel is not on the bridge for the E 65 loading; this upsets the proportion between the exact loading and the substitute loading; the latter was of course not intended for use in finding end reactions for Cooper's loading—neither were Dr. Steinman's curves, as the end reactions are given in a separate table. Neither is it my intention to propose the 8500 lb. per 100 ft. followed by 6500 lb. as a substitute for all cases.

In a 640-ft. two-hinged arch, the writer has used 9000 lb. for 110 ft., followed by 7000 lb. as a substitute for E 70, which would correspond to 8350 lb. for 110 ft. for E 65.

The method saves a considerable amount of time in reading curved influence lines.

4. I wish to mention the computations for the actually occurring engine loadings on railroad bridges 10 to 20 years old, of which, on most railroads, there are some of long span and many of shorter span. The following practical questions have frequently to be answered by the bridge departments, with short time available to answer them: Can these bridges carry some new heavy engines in permanent service or in transfer to some other railroad? Can they carry them as single engines or as double-headers? Can they carry them followed by 4000, 5000 or 6000 lb. per lineal foot? Can they carry them with or without speed restrictions? In such cases a uniform load substitute for the engine and another for the tender will be found useful and time-saving, especially if influence lines have been drawn up for the bridges in question.

C. L. CHRISTENSEN,
Assistant Bridge Engineer, Niagara River Bridge,
Michigan Central Railroad Company.
Detroit, Mich.

More Light on Fair-Compensation Contracts

Sir—Your editorial in the issue of Dec. 26, 1918, p. 1156, relative to fair-compensation contracts, is very much to the point, and suggests the need for vigorous action to secure an equitable form of contract for public works practice. May I suggest that such action might well take the form of an editorial or article showing how the cost-plus contract should be drawn to guarantee the public interest, and that the rule of equity requires that equity must be done if it is to be invoked?

You state that this form of contract has demonstrated itself to the public. Then why, unless the demonstration has been unfavorable, has Congress legislated it out of existence? Why does one constantly hear that boys of 16 and 18 are hired as carpenters at fancy wages, that they are sometimes put to digging ditches, that they are encouraged to take Saturdays off and work Sundays at double pay, that everyone who ever asked for a raise got it, that men check in in the morning and then spend the day working somewhere else, and many similar tales, all to the benefit of the contractor's per cent.? There is a wide-spread belief that the cost-plus contract has enabled many contractors to get rich by deliberately increasing the cost of the job, and sometimes this belief rests upon facts personally known to those holding it.

Many of these things are petty, most of them can be explained by the emergency of war and are not the deliberate act of the contractor, but if this form of contract is to be restored to public favor their recurrence must be prevented by the terms of the contract itself, and the public convinced that such terms are in such contracts. Any other action by associated contractors will be regarded by the public as actuated by selfish, if not dishonest, motives and will fail to restore such contracts to public favor.

H. E. PHELPS,
Assistant Sanitary Engineer,
United States Public Health Service.
Petersburg, Va.

Repair Heaved Brick Pavement at Oak Park, Illinois

Sir—During 1917, three-quarters of a mile of brick pavement was laid at Oak Park, Ill. The specifications were drawn for the monolithic type. After ¼ mile had been laid according to this method, permission was given to lay the remainder according to standard specifications for the cement-sand-bed type. One-half mile of the latter type was laid in 1918. Expansion joints ⅝ in. wide were provided at the curbs, and a prepared asphalt filler was used. In the cement-sand-bed type, a 1-in. bed of 1 : 4 cement and torpedo sand was used.

CONCRETE BASE CRUSHED AND BRICK LOOSENED FROM CEMENT-SAND BED BY HEAVE

During the winter of 1917-18, the monolithic pavement developed several longitudinal cracks, some of which were 150 to 200 ft. long. All of these cracks appeared on or near the center line of the pavement. Fine transverse cracks were noticeable in pavements of both types early last spring.

When the first warm weather came in the summer, the upheaval shown in the view occurred at the joint between a brick pavement of the cement-sand-bed type and an asphaltic concrete pavement on a 6-in. concrete base. The brick pavement which caused this "heave" was laid in the fall of 1917, average temperature about 40° F. The heave at this joint reached a maximum of about 5 in. above the normal surface of the pavement. Heavy

traffic was also destroying the grout filler between the bricks for a distance of about 2 ft. from the joint.

Investigation showed that the concrete beneath the asphaltic concrete pavement was pushed up and shattered by the expansion of the brick wearing surface. The grout-filled brick expanded independently of the base. It was found that the brick had pulled away from the base. and in some cases from the cement-sand bed.

No great difficulty was encountered in breaking through the concrete under the bituminous pavement, as the bond was completely destroyed. The concrete beneath the brick was found to be intact. The fact that the base under the bituminous pavement was destroyed, while that under the brick remained whole, may be explained by the fact that the subgrade beneath the asphaltic concrete pavement is 3 in. above that under the brick pavement. Because the brick pavement with its base was the stronger structure, the weaker one gave way.

The contractor who laid the brick pavement was instructed to make repairs as follows: (1) Remove the pavement and base on both sides of the joint, back as far as there was evidence of any disturbance; (2) instead of relaying the concrete base, lay a bituminous concrete base. similar to "closed binder"; (3) relay both brick and asphaltic wearing courses on this new foundation; (4) Fill spaces between bricks with some first-class bituminous paving filler.

After the experience of two seasons with brick pavements of the two types mentioned, we have decided to abandon both and specify an asphalt or pitch mastic bed and asphalt filler for all brick pavements on concrete base.

The writer cannot help but emphasize again the necessity of having a dry subgrade when paving foundations are laid, and the all-important need of providing real drainage beneath pavements. General paving practice does not consider the drainage question as it must be considered in order to have good pavements. It seems that any initial saving made by the present methods of construction is in reality false economy.

H. W. SKIDMORE,
Construction Engineer, Public Works Department.
Oak Park, Ill.

Further Tests on Time of Mixing Concrete

Sir—I was much interested in your editorial in the issue of Nov. 28, 1918, p. 966, under the heading "Minute Mix Justified by Extensive Tests." In that connection, I am handing you herewith the results of some experiments, which—although not extensive enough to be conclusive—point, I think, in the direction of the truth.

It was my privilege to be employed as engineer of tests on one of the large Government projects last summer, and I carried out, rather hastily, some experiments along this line, incidental to routine testing. The stimulus for my investigation was the "batch-a-minute" slogan of the manufacturers of which you speak, and a specification of one of our larger railroads which requires that "after all the ingredients are in the mixer the drum shall be given four complete revolutions before discharging."

There were in use on the job more than 50 mixers, representing all the well known makes. The aggregates in use were crushed limestone, river gravel, bank gravel, river sand, bank sand and limestone screenings. In connection with the routine testing, full notes were kept regarding the field conditions, the consistency of the concrete, the length of the period of mixing, the size and kind of mixer, and the proportions of the mixture. A wide variation was found in the compressive strength of the concrete, and when an attempt was made to group the results so that a study could be made of the effect of the time of mixing, no conclusions could be drawn because of the great diversity of elements in each group. It would be obviously unfair to compare, for instance, a sloppy concrete made with bank gravel and limestone screenings with a concrete of normal consistency, using crushed limestone and river sand as aggregate.

Accordingly, near the close of the work a series of experiments was undertaken, using the same aggregate in each of six different mixers, representing two distinct types. Particular care was exercised to secure the same consistency, as nearly as could be judged. There was no means available for measuring the amount of water. Four batches were made with each mixer, one each at four turns, eight turns, 12 turns and 16 turns of the mixer. From each batch six 6-in. cubes were made, three of which were tested in seven days and three in 14 days. The specimens were stored in wet sand in the interval between making and testing. The results are summarized in the accompanying table.

TABLE SHOWING EFFECT OF TIME OF MIXING ON STRENGTH OF CONCRETE

Mixer No.	Compressive Strength in Pounds at Seven Days, Average of Three 6-inch Cubes			
	4 Turns	8 Turns	12 Turns	16 Turns
1	1080	1520	1340	1140
2	1280	1480	1030	1270
3	1600	1100		1080
4	850	1050	1120	1220
5	830	1050	1090	1090
6	1060	1090	1140	1190
	Compressive Strength in Pounds at 14 Days, Average of Three 5-in. Cubes			
	4 turns	8 turns	12 turns	16 turns
1	960	1650	1440	1360
2	1370	1630	1190	1320
3	1490	1490		1290
4	1100	1610	1610	1660
5	990	1140	1220	1250

Mixer No.	Size in Cu.Ft. of Unmixed Material	Revolutions per Minute of Mixer Drum
1	21	13
2	21	13
3	14	13½
4	17	14½
5	21	10½
6	14	14

As an explanation of the above reference to types, it may be said that mixers may be classified, according to the construction in the drum, into two well defined types: Those with buckets which carry the concrete up near to the top and then drop it, and those without buckets. In all of them the arrangement of vanes and buckets varies somewhat, but the bucket is the principal distinguishing feature.

Mixers 2, 3 and 6 are of one type, and 1, 4 and 5 are of the other, although No. 1 is on the borderland between the two, having some of the features of both. Attention is called to the results of the tests on mixers 2 and 3. Both produced better concrete at four turns and eight turns than at 12 turns and 16 turns. The

cause of this cannot be ascertained from the data at hand, but it is significant that such excellent concrete was produced in such a brief period of mixing.

I am of the opinion that the ability to produce good concrete in a brief period of time depends a good deal on the construction of the mixer. It is unwise to claim much on the evidence of a few experiments. Nevertheless, it seems to me that this point deserves the careful consideration of engineers and manufacturers, and more careful and more nearly complete experimental data.

University of Kansas, Lawrence. J. O. JONES.

What Is A Right-Hand Door?

Sir—There seems to be a difference in opinion as to the definition of right- and left-hand doors. Can you quote any authority which will settle the question?

The writer has always been guided by the following definition:

"The hand of a door is determined from the stop side. If the butts are on the right-hand side, it is a right-hand door. If the butts are on the left-hand side, it is a left-hand door." H. L. CONRAD,

South Bend, Ind. Engineer, H. G. Christman Co.

A Hint to Engineer Employers

Sir—Referring to "Positions Vacant": You might drop a hint to the Illinois Highway Department to the effect that if it needs civil engineers competent to make surveys, prepare plans and supervise construction, it will have to offer more than $100 to $140 per month. Trolley conductors and motormen get $5 and over per day, time and a half for overtime and double time for Sunday work. It takes about a week to qualify for a conductor or motorman, while an engineer has to spend four years in a college or university and about $3600.

Why *Engineering News-Record* should continue to publish such ridiculous advertisements is more than one can understand. Your editorial utterances and advertising columns do not seem to agree.

There are secretaries of our national engineering societies, engineering foundations and councils who draw salaries of $10,000 or more per annum—four or five times as much as the average civil engineer gets. They enjoy two or three months' vacation every year, and do nothing but write letters, reports and resolutions, which in the end amount to nothing. And we are fools enough to continue paying our dues. Can you explain it? M. AM. SOC. C. E.

Engineers and Draftsmen Are Organizing

Sir—Referring to the letter in your issue of Dec. 26, p. 1192, by A. F. Barnes, dean of engineering, State College of New Mexico, relative to the low salaries paid by the Government to engineers, and the necessity for an organization of engineers to promote economics, I take this means of informing Mr. Barnes and all other engineers that there is now in the course of formation a union of engineers and draftsmen, throughout the United States, which is affiliated with the American Federation of Labor.

It is the object of the organization to promote the general welfare of all engineers and draftsmen, and particularly those in the Government service, who have been shamefully neglected for many years past; even at this time they are compelled to make a desperate fight in order to put in effect the wage adjustment of the War Labor Board.

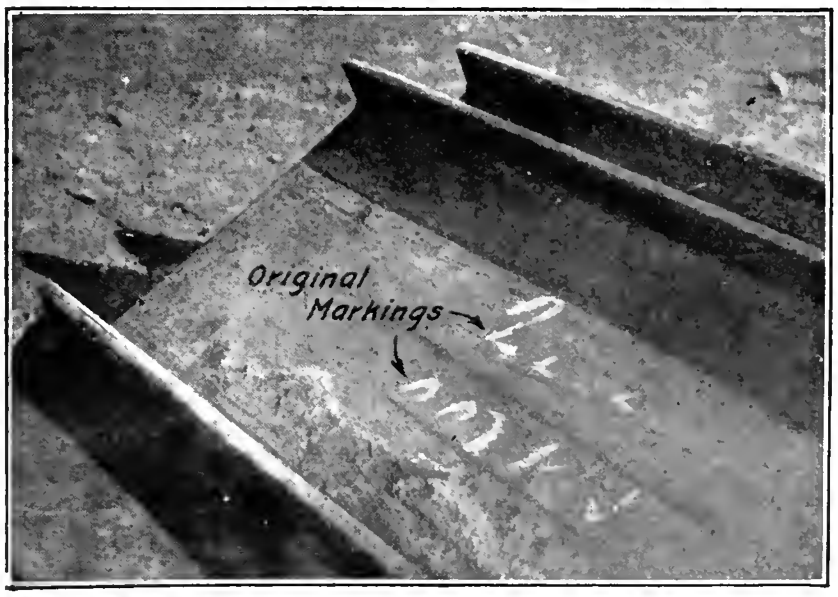
As stated by Mr. Barnes, the engineers and draftsmen have spent their every effort for the successful conclusion of the war, and in return have not received the slightest consideration from the Government. The other trades have forged ahead, raising their wages, bettering their working conditions through the influence of organization, but the engineers, mainly on account of lack of organization, have lagged behind. It is their intention, however, to make the influence of their organization felt, and for the information of any who may be interested, I solicit their correspondence.

This may be interesting information not only to Mr. Barnes but also to all engineers and draftsmen throughout the country. I know of no better means of putting it before them than through the columns of your paper.

R. N. ATHERTON, M. E.,
Vice President, Washington Society of Draftsmen.
Ordnance Department, Washington, D. C., Navy Yard.

I-Beams Retain Marks Thirty Years

Sir—The photograph here reproduced shows I-beams removed in November, 1918, from the Woodcliff reservoir, Woodcliff, N. J. These beams were used in the construction of bridges built by the County of Bergen approximately 25 or 30 years ago. They were abandoned when the area was converted into a storage reservoir by the Hackensack Water Co., in 1905. Since then



MARKS ON BEAMS VISIBLE AFTER THIRTY YEARS

there have been two occasions when the reservoir has been drawn down so that the I-beams were exposed; in one case for a period of about 30 days and in the second case about six weeks. Other than the two periods mentioned, the I-beams have been constantly under water. The beams were incased by brick arches, and when they were removed, it was noted that the paint was still on the surfaces of the beams where they had come in contact with the masonry. It was further noted that the white pointed figures, denoting lengths, were still visible in a great many cases. R. P. MCCLAYE,

Hackensack, N. J. County Engineer.

HINTS FOR THE CONTRACTOR

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Single Air Header Supplies Eleven Drills

ONE 3-in. air hose was made to supply eleven drills, in shaft sinking, by feeding to the suspended metal "header" hung from a cable in the center of the shaft just above the bottom being drilled. Eleven 14-ft. hose lines led off from the bottom of the header. There was also one connection for a blowpipe. Eleven drills were operated and two drills were kept as spares. When all was in readiness for blasting, the header and hose were hoisted out of danger, and were lowered again when drilling was resumed. A round of 45 holes, averaging 8 ft., were drilled in 2½ to 3 hours. The 11 x 21-ft. shaft was sunk for the Seneca Mining Co., Mohawk, Mich.

Progress Chart for Recording Preparation of Construction Plans

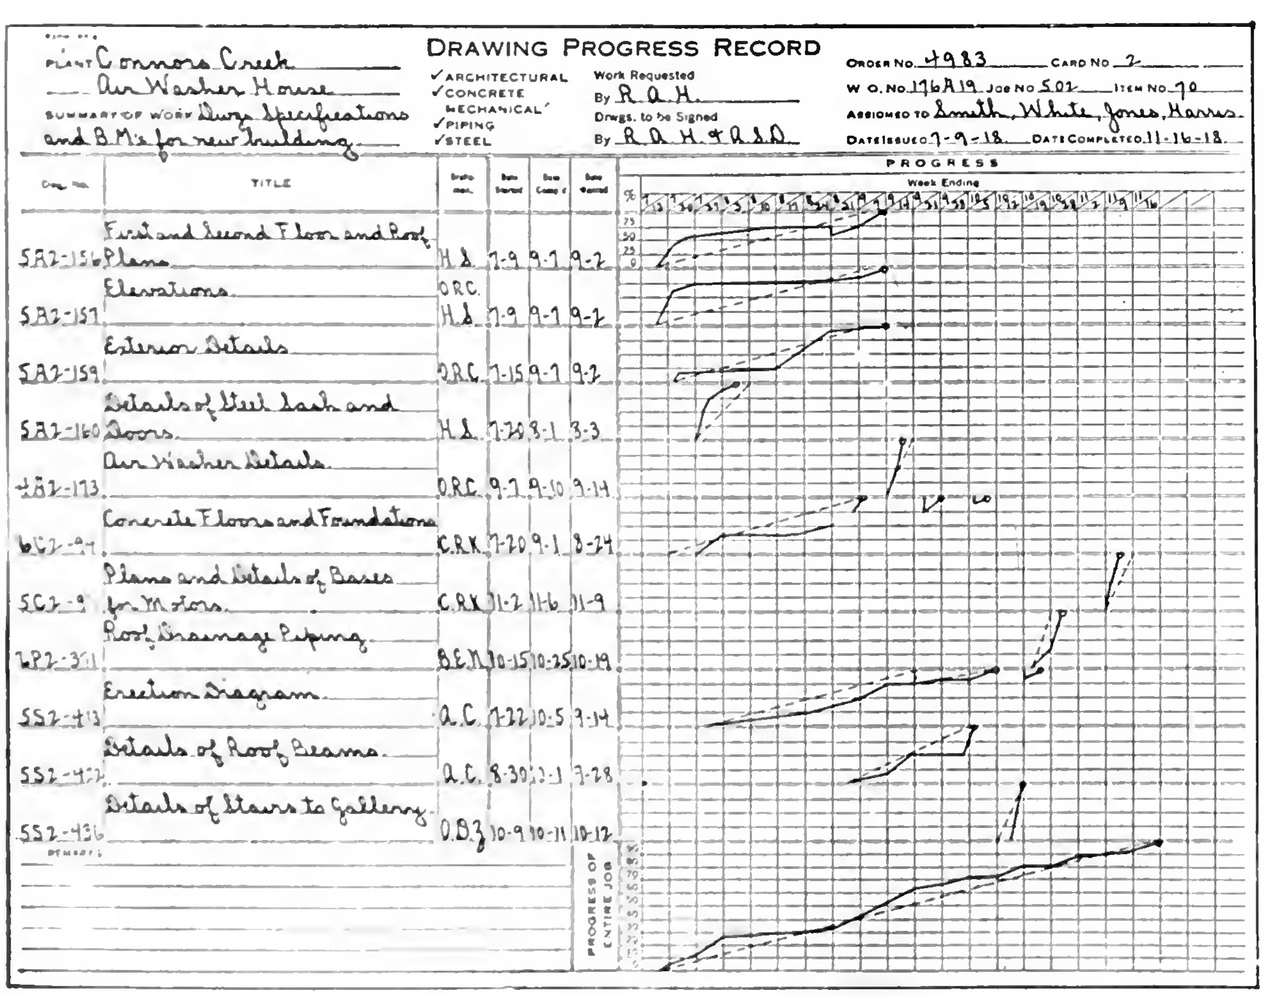
THE progress of every drawing required for the construction work of the Detroit Edison Co. is recorded on 8½ x 11-in. cards of the type shown by the illustration. For small jobs, one card is used, but for larger jobs as many cards are made out as there are important divisions of the work. In the illustration, a number of drawings from different cards are entered, to show the variety of records possible.

All the drawings to be made are entered on the card with the other information, as shown. The date on which each drawing is wanted is also shown, and a dotted line shows the progress that should be made to complete it in the required time. The actual progress made is shown by a full line for each drawing, while at the bottom of the card a curve on a larger vertical scale shows the progress for the entire job.

Watching these curves, one can readily see which drawings are progressing properly and which are being held up, for when a horizontal line appears it signifies that work has stopped. The reason is entered on the back of the card, where there is also a place to note all changes made that retard completion; also any information that is essential before the drawings can proceed is noted in a place for that purpose.

When a change is made, which is not an uncommon occurrence, the curve drops in proportion to the extent of the change. The back of the card also contains the order for the work in full and a list of all the bills of material, which are entered as they are completed. This is of great assistance in determining if everything has been ordered for the job. It can be seen that the card becomes a reference card after the office work is completed and its function as a progress record is done.

When the drawing is completed and leaves the drafting room, a circle is placed at the end of the curve, as shown. In case revisions are made after the drawing has been completed, they are indicated as shown for drawings "6 C 2 — 94" and "5 S 2 — 413." The drawings and the bills of material, upon leaving the drafting room, go to the estimating department for estimates and work orders. They then proceed to the office of the construction engineer for approval, after which they are sent to the order department, where materials are ordered and blueprints sent to the field or elsewhere, as the occasion demands.



PROGRESS CHART SHOWS STATUS OF EACH CONSTRUCTION DRAWING

It is necessary that each drawing be completed on time so that the material billed from the drawing will be on the job when it is needed. A glance at drawing "5 A 2 — 160" will show how this is done. The steel sash must be ordered many weeks before it is needed; therefore, when the plans and elevations are far enough advanced so that the number and size of the windows can be determined, the sash details are started and brought to completion as rapidly as possible. The direct opposite of this is shown by

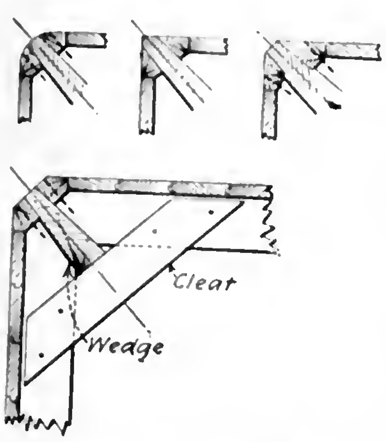
drawing "5 C 2 — 96." These bases were not needed until the building was well under way, so nothing was done on the drawing until the other drawings were completed.

This method of recording progress of drawings is described by J. C. Thornton in the *Synchroscope* for January, 1919.

Formwork Easily Stripped by Use of Special Corner Detail

By L. Kopczynski
Wilmington, N. C.

THERE has always been some trouble in stripping of forms in reinforced-concrete work, especially in angles which become wedged tightly. The sketch is self-explanatory. All the pieces are milled; no handwork fitting is necessary. Using a gage for holding the corner, it can easily be assembled by one man, and the forms will be made rigid and strong by nailing the corner cleat, if possible, with double-headed nails. The removal of this cleat will allow the wedge to be driven out, and the forms are easily stripped. This appliance is called "Kop's Corner," and I would be pleased if the contractors would introduce it in their work by that name, as it is cheap and no royalty is involved. It saves material and labor—also the religion of the strippers. The corner can be elaborated, made as shown in the sketch, or rounded off, or given any form desired.



CORNER DETAILS MAKE STRIPPING EASY

Ample Clearance on Scaffold Runways Saves Working Time

MAKING scaffold runways around the hull of ample width is an important detail in good shipyard management, says a shipbuilder who had occasion to work in various shipyards last summer. The runways should be wide enough to let the men passing along clear the men working on the side of the ship. In one or two yards the walks are so narrow that men coming up the stairways and going along a runway are bound to interfere with the work of reaming and riveting gangs. Such an encounter means that both parties lose time. In addition to the waste of labor expense, the progress of the ship is delayed, which means a distinct additional expense item.

At one yard the rule was made, in the initial design of the scaffolding and the layout of berth space to accommodate it, to provide for three 10-in. planks as minimum runway width on the overhang of the scaffold ledges. This is by no means ample provision, says the shipbuilder, but it is vastly better than an arrangement that provides for only two planks.

In details of this kind it is easy to lose a large part of the gain in working efficiency secured through well studied plant layout and good equipment. Failure to provide proper runway capacity can only be attributed to lack of care, because there is no advantage in compactness of scaffolding in itself.

Caisson Chambers Concreted in Sections

ASSURANCE that the concrete seal would fill closely all corners was sought by concreting the working chambers of the large pneumatic caissons of the Metropolis bridge in four sections.

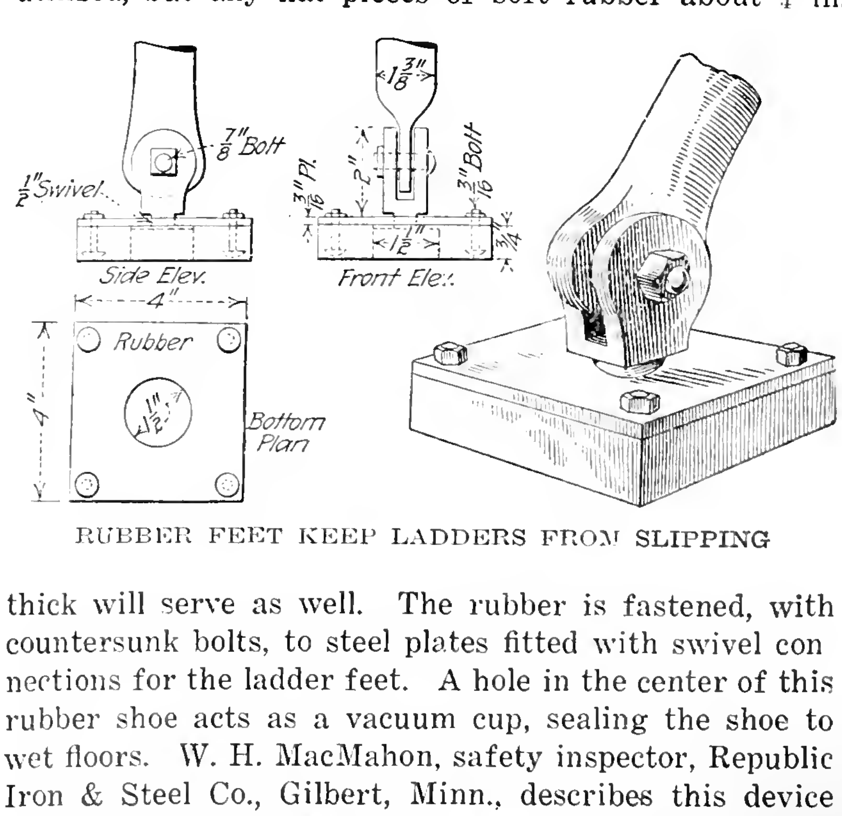
These caisson chambers varied in size from 80 x 47 ft. to 110 x 60 ft. Ordinarily, in filling such chambers there is a doubt whether the concrete has penetrated to the farthest corners of the caissons, after they have been filled to such an extent that men cannot work in them. To relieve this doubt at Metropolis, bulkheads were built across the working chambers so as to divide them into four sections each. The two end sections were concreted first. Then holes were bored through the bulkheads to determine whether at any point cavities existed in the concrete filling. One of the middle sections was then concreted and tested for solidity.

Finally, the last section was concreted. This section could not, of course, be tested as were the others, but its small size decreased the chances that the concrete would not flow to all parts.

According to G. A. Haggander, bridge engineer of the Chicago, Burlington & Quincy R.R., the sectional method of sealing the caissons probably presented no construction advantage such as reducing cost of plant or amount of labor, but it did enable the engineers to ascertain with certainty whether the chamber had been solidly concreted.

Safety Feet for Ladders Made With Rubber Pump Valves

LADDERS to be used on concrete or metal floors can be made safe from slipping by fitting them with rubber feet, as indicated by the accompanying sketches. In this particular case soft rubber pump valves were utilized, but any flat pieces of soft rubber about ¾ in. thick will serve as well. The rubber is fastened, with countersunk bolts, to steel plates fitted with swivel connections for the ladder feet. A hole in the center of this rubber shoe acts as a vacuum cup, sealing the shoe to wet floors. W. H. MacMahon, safety inspector, Republic Iron & Steel Co., Gilbert, Minn., describes this device in *Engineering and Mining Journal*.



RUBBER FEET KEEP LADDERS FROM SLIPPING

Committee to Revise Federal Shipbuilding Program

Five Shipping Men and Two Officials from Fleet Corporation to Examine Present Plans

The United States Shipping Board has announced the personnel of the committee to examine the building plans of the Emergency Fleet Corporation, with a view to such revision as might be wise in view of the altered international situation.

This committee is to consist of J. A. Farrell, president of the United States Steel Corporation; P. A. S. Franklin, president of the International Mercantile Marine Co.; George S. Dearborn, president of the American-Hawaiian Steamship Co.; H. H. Raymond, president and general manager of the Mallory Steamship Co., and F. D. M. Strachan, president of Strachan Shipping Corporation. In addition to the foregoing, Charles Piez, director general of the Emergency Fleet Corporation, and John H. Rosseter, director of operations of the United States Shipping Board, will be ex officio members of the committee. Of these, Mr. Dearborn and Mr. Raymond are the nominees of the American Steamship Association, which was asked to designate two of its members for places on the committee.

New Questions Arising

Until hositilities ceased the purpose and effort of the Fleet Corporation was to produce useful tonnage in the largest possible quantity to keep pace with the growing need of tonnage as our overseas forces increased, and to repair the destruction wrought by submarines. With the signing of the armistice, the problem of the Fleet Corporation took on a different aspect, and the question now is, "What revisions of type are advisable and what modifications of plan or practice can be undertaken to give the Fleet Corporation's output of ships as high an economic value in world trade as possible?"

The lifting of the pressure, both of need and time, which controlled the Fleet Corporation's decisions during the actual continuance of war, makes it possible to give more consideration to economic standards, and the Director General and the other officials of the Fleet Corporation have for many weeks been engaged in a thorough examination of the corporation's building plans, and have themselves developed some important suggestions. It is to test these proposed alterations of program that the committee above named has been appointed.

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

Division of Engineering, United States Employment Service; A. H. Krom, director, 29 South La Salle St., Chicago, Ill.

Professional and Special Section, United States Employment Service; George W. Kirchwey, state director, 1? East 42nd St., New York City.

Bill Provides for Federal Public Works

Senator Kenyon, of Iowa, chairman of the Senate committee to investigate labor conditions, has introduced a bill appropriating $100,000,000 for expenditure on public works. It would create an agency known as the United States Emergency Public Works Board to supervise expenditure of the fund and to have general charge of Federal, state and municipal developments to check unemployment.

Besides the $100,000,000 emergency fund Senator Kenyon proposes to authorize advances by the War Finance Corporation to the extent of $300,000,000, upon approval of the Federal board, for public works certified to be necessary by the Secretary of Labor to prevent unemployment.

Kansas Good Roads Association Favors $60,000,000 Bond Issue

At a recent meeting in Topeka the Kansas Good Roads Association started a campaign to have the coming legislature submit a constitutional amendment at the next election that will permit the state to aid in good roads construction, and also to submit a bond issue for $60,000,000 to provide for this aid.

A system of 5000 miles of hard-surface highways, which will connect every county seat and market center in the state, is planned. To help finance the system, it is proposed to change the motor-car registration and license law, from one based upon a flat fee of $5 per year, to one based on the horsepower of the car, the revenue to be utilized to pay the interest and principal.

Tariff Commission Favors Free Zones

Urges Immediate Congressional Action Permitting Their Creation, To Foster Foreign Trade

Free ports or zones should be permitted in the United States, in the opinion of the United States Tariff Commission, which has just made an exhaustive report on the subject to the Committee on Commerce of the United States Senate. The legislation which it recommends—a revision, in part, of two bills now before Congress—is merely permissive in character. It leaves the initiative to the locality and puts upon it all risks and responsibilities. Each state or political subdivision thereof is permitted to establish and equip at its own expense a zone wherein foreign merchandise may be entered free of duty.

As defined by the report, a free zone is "an isolated, inclosed and policed area in or adjacent to a port of entry, without resident population, furnished with the necessary facilities for lading and unlading, for supplying fuel and ship stores, for storing goods and for reshipping them by land and water; an area within which goods may be landed, stored, mixed, blended, repacked, manufactured, and reshipped without payment of duty and without the intervention of customs officials. It is subject equally with adjacent regions to all the laws relating to public health, vessel inspection, postal service, labor conditions, immigration, and, indeed, everything except the customs." The purpose of the free zone is to encourage and expedite that part of a nation's foreign trade which its Government wishes to free from the restrictions necessitated by customs duties. It aims to foster the dealing in foreign goods that are imported, not for domestic consumption but for reëxport to foreign markets and for conditioning or for combining with domestic products previous to export.

At present the only provisions to take care of such reëxporting lie in the bonded warehouse, the bonded manufacturing warehouse and the drawback system. None of these, in the opinion of the Commission, is adequate to foster the foreign reëxport trade which is now necessary to this country. All three are cumbersome in their operation and limited in their application. In the opinion of the commission, the business proper to a free zone consists in receiving and manipulating the foreign products and reshipping them in the direction and at the time to take advantage of the best foreign markets. This is not only a profitable business, but is also becoming

a necessary business in our industrial growth, for, however wide the range of goods we produce and however effective our methods of production, we can sell our products to best advantage only when the purchasers are able to pay for them with products of their own. If we do not accept their products they must sell them in some third country and transfer to us the credits that they thus acquire — unless, indeed, they forego buying our goods at all and make their purchases in the country where they make their sales.

Transshipment trade in the United States has been steadily declining since the banner days of American shipping, but the present conditions are very favorable to its revival. In the opinion of the commission, however, the burden of the free port or zone must lie upon the locality which desires it, and the only function of the Federal Government is to provide laws whereby the zone may be operated.

The report details under the following heads the advantages to be expected from the free zone system: The simplification of entry and clearance, the equalization of the inbound and outbound traffic, the facilitation of dealings in foreign products, the stimulation of certain branches of manufacturing and the stabilization of transshipment trade under varying tariff policies. The commission feels sure, after a lengthy study of the theory of the subject—amplified by hearings in many of the ports of the country and the study of the answers to questionnaires sent out to merchants and shippers—that the time is now ripe for the development in the United States of this type of port, which has already proved successful in several European cities, notably Copenhagen, and Hamburg.

Engineering Council Acts on Public Service Engineers' Discharge

Following the hearing held last week on the dismissal of over 300 engineers of the Public Service Commission of New York City, as reported in *Engineering News-Record* of Jan. 16, p. 163, the Engineering Council Jan. 16 adopted a resolution urging the Board of Estimate and Apportionment of the city to reconsider its action. The resolution is based on a statement of findings in which it is asserted that the city's rapid-transit construction work will be seriously hampered and delayed by the disruption of a highly specialized trained organization built up to carry on this work; that the dismissal of 339 men of the engineering force by effect of the "line budget" adopted by the Board of Estimate Dec. 30 was an injustice of which no employer should be guilty; that the alarm of the laboring men employed on subway work over the curtailment of proper engineering inspection and supervision is justified and should be heeded; that the Board of Estimate's action will result in the discharge of a considerable body of labor and will prevent the employment of additional labor for the sections for which contracts were to have been let, which action is contrary to economic wisdom; that large loss to New York City is threatened through claims for delay which will arise from the disruption of the engineering force; and that the noncompletion of certain subway sections, preventing operation of trains in other sections, involves a striking waste of public funds. On this showing the action described below was taken:

"In view of the above facts, Engineering Council, representing the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, having a membership of over 36,000, which body is vitally interested in engineering and is qualified to speak in matters involving the satisfactory direction of engineering work, hereby adopts the following resolution:

"Resolved, that in view of the above facts, the Board of Estimate and Apportionment be urged to reconsider at once its action of Dec. 30 and to make such appropriation as will enable the Public Service Commission to carry on with safety and economy the rapid completion of the subway work, and that the Board of Estimate should leave to the Public Service Commission, on which the law places the responsibility, the detailed apportionment of these funds in accordance with a practical schedule to be prepared by it and submitted to the Board of Estimate for its information."

Little Government Surplus of Building Material

Conference Called By War Industries Board Shows That Excess Material Can Be Absorbed Readily

At a conference called by Richard L. Humphrey, director of building materials, War Industries Board, at Washington last week, it was announced that little trouble was anticipated in disposing of the Government's surplus stock of building materials. At the conference were represented the various Government agencies which had been purchasing and using building materials, and representatives of the building material War Service Committees.

The subject of the disposal of surplus stock was thoroughly discussed, and the following facts were developed:

1. That the Government agencies are not going to dispose of surplus stocks of building materials in such a way as to disturb market conditions.

2. That these surplus stocks are being rapidly absorbed by redistribution among the several Government departments so that the greater portion of these materials will be thus cared for.

3. That, with the exception of lumber, the amount of these surplus stocks is very small, and cannot materially affect market conditions.

4. That the largest single material was lumber, and in connection with it a plan was unanimously agreed to, and is now being considered by the industry, whereby the Government will in a suitable manner dispose of amounts too small to affect the market in any way; where large amounts are concentrated the disposal will be made in conjunction with the industry. It is estimated that the total amount of this surplus stock does not constitute more than one-sixth of the normal monthly output of lumber for the entire country. The same plan is to be applied to other building materials, and is being considered by these industries.

Estimates of the amount of building materials the Government has on hand are given below. Accuracy in the estimates is not possible, but there is reason to believe the figures do not contain an error larger than 25 per cent.:

Commodity	Quantity
Brick	14,516,000
Hollow tile	2,235,403 pc.
Lumber ft. b. m., veneers and plywood	350,000,000
Cement	115,523 bbl.
Lime	77,560 bbl.
Flue linings, lin.ft.	29,226
Metal Lath, sq.ft.	1,122,313
Wood Lath	2,695,000
Wallboard (all kinds)	5,406,429
Roofing, rolls	202,208
Building Papers, rolls	52,377
Nails, assorted sizes	159,622 kegs
Reinforcing steel	3,000 tons
Sewer pipe, assorted sizes, lin.ft.	577,407
Wood shingles	908,000

Indiana Highway Commission Law Declared Constitutional

After several months of litigation, the State Highway Commission of Indiana and the statute under which it operates have been declared constitutional by the State Supreme Court. This will allow extensive highway improvements, which had been held up pending the decision, to go forward.

The decision was rendered in a taxpayer's suit instituted by Robert M. House of Hamilton County, who averred through his attorney that the law in its operation would be confiscatory, in that it took money from him without giving him a return equal to that given to taxpayers living on the road or nearer it than he. It was claimed that this is contrary to the 14th amendment of the Constitution of the United States, which prohibits taking property without due process of law.

It was argued that the statute was void in that it created offices and provided for the expenditure of money not specifically authorized by the state constitution. A lower court sustained these contentions and declared the law unconstitutional, as reported in *Engineering News-Record* of May 16 ,1918, p. 976. Editorial comment upon the action of the state Supreme Court in taking a three months' vacation, further delaying a decision on appeal, will be found in *Engineering News-Record* of July 18, p. 109.

The state Supreme Court has finally overruled the lower court, and, as a result of this decision, it is proposed

to start immediately construction on approximately 120 miles of main market highway, from Indianapolis to South Bend, which is estimated to cost $3,000,000.

It is further asserted that the decision upholds the validity of acts creating other state offices, and in general indicates that the Indiana constitution is a guaranteeing rather than a limiting instrument.

Ohio Good Roads Congress in Joint Sessions

The second annual joint convention of the Ohio Good Roads Federation, the Ohio Engineering Society and the County Commissioners' Association of Ohio held in Columbus, Ohio, Jan. 14-16, developed a variety of topics, but the central theme of all discussions was, "Get Ohio out of the mud."

The first session of the Ohio Engineering Society was addressed by Pres. Thomas J. Smull, who reviewed the work of the society for the past year and made recommendations for the present year. Among them was the further improvement of the service bureau inaugurated by Sec. John Laylin, and the desirability of final action upon the question of licensing engineers. C. E. Drayer, of Chicago, discussed "Licensing Engineers," and as stated elsewhere a resolution favoring licensing was passed unanimously.

Other speakers of the week on subjects of special interest were: "Recent Military Achievements with Concrete," by A. J. R. Curtiss, Portland Cement Association, Chicago; "Federal Highways," by H. S. Shirley, secretary of the Highway Industries Association, Washington, D. C.; "Road Improvements in Ashtabula County," by Ray Case, county engineer of Ashtabula County, Ohio; "Military Engineering with the American Expeditionary Force in France," by Capt. J. F. Mollenkopf, Van Wert, Ohio; "Report of Codifying Commission, Ohio Drainage Laws," by P. T. Ford, secretary of the commission, Ottawa, Ohio; "Public Utilities," by the Hon. Beecher W. Waltermire, of the Ohio Public Utilities Commission, Columbus, Ohio; "Production and Uses of Asphalt," by William Howe, Texas Co., Chicago.

The following officers of the Ohio Engineering Society were elected: President, Ett S. Smith, Youngstown; vice-president, Cecil L. Rood, Toledo; secretary-treasurer, John Laylin, Norwalk.

Akron Will Vote on $3,000,000 Sewerage Bonds

The city council of Akron, Ohio, has passed a resolution to submit to the voters Mar. 4 a proposed bond issue of $3,000,000 for the construction of trunk sewers and to pay the city's part of the cost of other sewerage work. This is part of a sewerage program estimated to cost $6,000,000, exclusive of the cost of sewage treatment. H. S. Morse is director of public service.

National Service Committee in Washington Office

Engineering Council Establishes Service for Engineers—Names of Members Announced

In order more completely to provide for united action upon matters of common concern to engineers, the Engineering Council has recently organized a National Service Committee and has established an office in the national capital. This action was based upon a tentative plan for representation of engineers at Washington, submitted to the council at a special meeting on Nov. 21, 1918, by Philip N. Moore, of the American Institute of Mining Engineers. (See the December *Proceedings* of the American Society of Civil Engineers.) The present member societies of the Engineering Council are the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the United Engineering Society and the American Society for Testing Materials.

The Engineering Council, through this National Service Committee and its Washington office, intends to accomplish the following general purposes, this committee acting always under the direction of the council and within limitations fixed for it:

1. To discover public services which may best be performed by engineering societies, and, when desired, to offer the proper men for such services.

2. To speak authoritatively for the Engineering Council before committees of Congress and departments of the Government on all public questions of common interest to engineers, within such limitations as the council may set from time to time.

3. To give promptly wide circulation among engineers to authentic information regarding pending legislation and executive actions which may affect the interests of engineers in any way.

4. To gather opinions of engineers on these matters.

The Engineering Council's aim is disinterested usefulness to the nation and the profession—not advocacy of any selfish ends—by giving unbiased information and counsel on technical matters, chiefly when asked. A modest start is being made. The work will be enlarged only as a real demand for services develops.

The members of the National Service Committee have been chosen so as to represent different parts of the country. The appointees are the following: Chairman, M. O. Leighton, M. Am. Soc. C. E., Washington, D. C.; C. B. Burdick, M. Am. Soc. C. E., Chicago, Ill.; George F. Swain, M. Am. Soc. C. E., Boston, Mass.; Philip N. Moore, M. A. I. M. E., St. Louis, Mo.; L. D. Ricketts, M. A. I. M. E., Warren, Arizona; Andrew M. Hunt, M. Am. Soc. M. E., San Francisco and New York; Andrew M. Lockett, M. Am. Soc. M. E., New Orleans, La.; W. C. L. Elgin, M. A. I. E. E., Philadelphia, Penn.; Bancroft Gherardi, M. A. I. E. E., New York.

The Washington office is located at 502 McLachlen Building, 10th and G Streets.

To Ask $500,000,000 for New Railroad Improvements

Director General Walker D. Hines announced Jan. 15 that the Railroad Administration is preparing to ask Congress for another revolving fund of $500,000,000 to be used in financing the program of railroad improvement that is now being planned by the Government. This program calls for a total of authorized capital expenditures for the years 1918 and 1919 of $1,627,000,000, and the Director General estimates that the minimum additional amount in the budget for 1919 must be $350,000,000. The new fund would bring the total appropriated by Congress for the Railroad Administration up to $1,000,000,000.

The Director General states that it is to be understood that none of this fund is to used to pay the deficit of nearly $200,000,000 incurred by the war emergency operation of the railroads in 1918. He distinguishes two functions of the Railroad Administration under Federal control: (1) To render public service through operation of the railroads, collecting of the revenues therefor, and paying the expenses and the rental due the railroad companies. The other function is to require that necessary permanent improvements be made, including purchases of new equipment. He believes that the carrying out of the second function may call for the temporary use of a great deal more Government money than is needed for the first.

American Railway Association Is Reorganized

The Director General of Railroads announces that during the period of Federal control, in order to provide a responsible channel through which he may obtain recommendations for the advancement of railroad practice, the American Railway Association will change its name to the American Railroad Association. Its scope has been enlarged and will cover the former activities of the following organizations: The American Railway Association; American Railway Master Mechanics' Association; Association of Railway Telegraph Superintendents; Association of Transportation and Car-Accounting Officers; Freight Claim Association; Master Car Builders' Association; Railway Signal Association; and Railway Storekeepers' Association.

The new organization will consist of five sections: 1, Operating; 2, engineering; 3, mechanical; 4, traffic, and 5, transportation. Railroads under Federal control are members of the association and are directed to appoint representatives and participate in the activities of the association through their proper officers.

Honor Achievements of Construction Division

Brilliant Dinner at Washington to General Marshall and Officers Marked by High Enthusiasm

To celebrate fittingly the construction achievements of the Army in this country during the war, Brig.-Gen. R. C. Marshall, Jr., and the officers of the Construction Division were entertained at a dinner by their friends at the New Willard Hotel, Washington, last Friday night. Four hundred and thirty persons were present, half of them being officers and the others the hosts of the evening. An elaborate program had been prepared, consisting of vaudeville acts and a sketch, written and acted by officers of the division, hitting off the little failings of their prominent brother officers and making good-natured fun of incidents and practices in the work of the division. The evening was notable for the remarkable enthusiasm and spirit of fellowship which prevailed throughout the evening, experienced diners-out declaring it one of the most successful of big Washington dinners.

The reason for the celebration was well expressed by Assistant Secretary of War Benedict Crowell when he declared that the Construction Division "had done a 100% job." The toastmaster, E. J. Mehren, editor of *Engineering News-Record*, paid high tribute to General Marshall and the officers of the division, declaring their work to be the greatest construction achievement under a single organization in the history of the world. He commended the vision displayed in outlining the policy of the division, and attributed the success of the work to the high character of the personnel, to the decentralization of authority, and to the spirit of fair dealing with contractors, manufacturers and labor which characterized the work of the division.

General Marshall, in acknowledging the tribute of the toastmaster, gave the credit for the Construction Division's work to the officers and men of his organization. He also gave full credit to the work of the manufacturers, declaring that those who stayed behind and produced supplies were the "unsung heroes of the war."

Tribute to the Construction Division

Mr. Mehren spoke in part as follows:

"In a general way we know what the Construction Division has done, but a few figures will serve to impress on us the magnitude of the task. It built in 90 days 16 soldier cities, each for a population of 40,000 (now increased to about 50,000), with all the utilities, such as water, sewerage, electric power and fire protection, that a modern city requires. This feat remains still the greatest single achievement of our war preparations. We had to have the cantonments quickly. We unloaded this unprecedented job on the Construction Division and they came back in 90 days with the job done.

"The work done by the division will total about $800,000,000 in cost, and of that huge sum $[illegible],000,000 was spent in a period of 15 months, a record for construction under a single organization that has never been approximated in the history of the world.

"Needless to say, the accomplishment of such a huge task economically and efficiently and at the same time at top speed required an extraordinary organization and exceptional vision and administrative ability at the top. The organization drew to itself the best brains of the country in the field of construction, and those in charge wisely gave full authority to the men in the field.

"With this type of personnel, and this broad-gaged delegation of authority from Washington, went a policy, handed down from the top, of fair dealing with the various contracting and manufacturing organizations selected to do the work and supply the materials. The Construction Division has done more in its brief life to establish a fair contract for Government work than have the contractors themselves in a whole generation. The cost-plus-limited-fee contract, as applied by the Construction Division, guaranteed justice to the Government and the contractor alike, and when that contract was challenged in the general criticism of cost-plus contracts, a board composed of the presidents of the leading engineering societies of the country studied the contract, and approved it in the very highest terms.

The Division's Labor Record

"Further evidence of the spirit of co-operation and fair play that characterized the work of the division is shown by its extraordinary labor record. Though during its operations its contractors employed 400,000 men, the labor troubles were negligible, all of them being handled by a staff of five, some of whom had other duties besides.

"Never has a body of engineers and constructors been called on to do so tremendous a job. Never were the conditions more unfavorable for success. The material that was in hand had to be used, rather than that which was most suited to the work, transportation facilities were terribly congested, labor was frequently inefficient. With these bad conditions were combined the enormous size of the job and the terrific speed with which every part of it had to be put through. Had there been in waiting a fully prepared organization, composed of trained men who had long worked together, the job would have been hard enough. But there was no organization. Thirty men constituted the available force in April, 1917. In a few months, however, the big job was running smoothly. By selecting the ablest construction men the country afforded, and uniting them under an intelligent, open-minded leadership, it has been possible not merely to master the job, but to do it with a brilliance that has attracted attention throughout the country.

"It is fitting, therefore, that those who have seen the organization at close range, and watched it expand from the original band of 30 to a smoothly functioning organization of 6000, should join in a public tribute to those who have written the name of the Construction Division so brilliantly not only into the history of the war, but into the engineering and construction annals of this country."

General Marshall's Reply

General Marshall paid tribute to his officers and the manufacturers, in the following words:

"In all modesty, I now distribute to the members of the Construction Division here tonight all of the kind words and the thoughts they express, which have just been uttered. Theirs the credit, and to them must it be given. Such statements as have just been made prove embarrassing to me, for to the success of this war there have been many contributors.

"Homeward the boys come—and to each shipload that lands at our ports there goes forth the gratitude of a nation. In pictures, in poetry, and in song are their valorous deeds portrayed. It is their just due. I do not in the least detract from the value of their bravery when I tell you of another hero.

"The unsung hero of this war is the man who remained behind, and, in the intensity of his devotion, to the very commonplace occupation of producing supplies for our Army gave his utmost to the Great Cause. He it is whose constant efforts made possible the victorious onslaught of the man whose privilege it was to face the enemy. In and out of uniform, on this side of the ocean, an entire nation contributed to its utmost capacity.

"The incessant booming of the guns on the Hindenburg line was only the echo of the constant whir of machinery on the manufacturers' line. The shout and battle-cry of our brave ones overseas was the reverberation of the order to workers on this side to produce. The camp-fires of France were kept brightly burning by the furnaces of America.

"From the very inception of our participation in this world war, the unanimous response of the man in business spelled 'Victory.' His loom, his lathe, his furnace—yes, his every energy—turned the profitable output of commercial products into the production of whatever form of munitions and supplies was asked for by the Government. From his door belched forth the contributions of an earnestly patriotic effort to wrest victory from a common enemy.

"To this American, represented by our hosts tonight, I lay the tribute of the Construction Division in gratitude for the help he has been in accomplishing the task given us to perform."

Brief Biographies of Engineers Who Handled War Construction Work in America

Men Who Have Had the Handling of $800,000,000 Worth of Buildings, From Cantonments to Huge Terminal Warehouses

Biographical sketches of the leaders in the Construction Division of the United States Army who have been handling over 300 projects in Army construction in this country, totaling $800,000,000 and ranging from cantonments — miniature cities in themselves — up to the $40,000,000 terminal supply base and warehouses in Brooklyn are here recorded to indicate the type of men who have successfully carried through one of the greatest construction activities of history. This work required at one time 300,000 men, and included camps, cantonments, arsenals, wharves, docks, forts, great port terminals, reserve storage warehouses, hospitals of all sizes and descriptions, aviation fields, proving grounds, embarkation camps, engineers' camps, gunnery schools, housing, lighterage, power plants, factories, additions to manufacturing plants, munitions works, and special new plants for the production of nitrates, phosphorus, etc.

Brigadier General R. C. Marshall, Jr.

America's Army cantonments stand as a monument to the energy and resourcefulness of Brig. Gen. Richard C. Marshall, Jr., chief of the Construction Division, a native of Virginia. As Colonel Marshall he undertook with Col. Isaac W. Littell the organization of the Cantonment Division of the Quartermaster Corps of the National Army in May, 1917. So successfully was this work prosecuted that mushroom cities on 32 sites were soon completed.

General Marshall was born in Portsmouth, Va., in 1879, and was graduated from the Virginia Military Institute in 1899. He was appointed captain in the Fourth United States Infantry on June 29 of that year, and honorably mustered out of service after having served through the Cuban campaign. In 1901 he was appointed second lieutenant in the Artillery Corps. He was an honor graduate at Fort Monroe, Virginia, class of 1904, was promoted to a lieutenancy in January, 1904, and in December, 1907, was made captain. In June he was detailed to the Quartermaster Corps, and served in the construction and repair branch until the beginning of the 1917 emergency.

When the cantonment construction was finished, all construction work of the Army was turned over to the Cantonment Division, on account of its excellent work, and it was made a separate corps, known as the Construction Division of the Army. Colonel Marshall, then a major, was made lieutenant colonel and placed in charge, and in March, 1918, he was promoted to a colonelcy. He became brigadier general in July, 1918.

Colonel Gunby—Engineering Division

Formerly a partner in the firm of Charles T. Main, of Boston, Col. F. M. Gunby, in charge of the Engineering Division, was called to Washington in May, 1917, to take charge of the engineering for the construction of the cantonments. An important part of his work has been done in connection with obtaining appropriations from Congress and the handling of funds and authorizations for the work of the Construction Division. He was graduated from Clemson Agricultural and Mechanical College, Clemson, S. C., in 1902. In April, 1913, he enlisted in Company G, Fourth Infantry, Georgia State Troops, and was discharged as first lieutenant in May, 1905.

He enlisted in Company C, First Corps Cadets, Massachusetts Volunteer Militia, in May, 1908, and was discharged in December, 1911. He was commissioned major in the Quartermaster Corps in 1917, made lieutenant colonel in February, 1918, and commissioned as colonel in March, 1918.

Colonel Bush—Engineering Division

Col. Lincoln Bush, assistant to chief of the Engineering Division, was born in Orland, Ill., in 1860. He was graduated from the Cook County Normal School in 1881 and from the University of Illinois in 1888. Before entering the service he had been division engineer of the Chicago & Northwestern Ry., Chicago, bridge engineer, and then chief engineer of the Delaware, Lackawanna & Western R.R.; consulting engineer, vice-president and treasurer of Flickwir & Bush, Inc., New York City. As consulting and contracting engineer he has been engaged in bridge work, foundation work, steam-shovel work, tunnels and subway construction, and is the inventor of the well known Bush trainshed.

Since joining the Construction Division he has designed terminal ports, warehouses, some ordnance projects, miscellaneous engineering works, etc., has given advice relating to field execution, and has acted as representative on projects designed and constructed for storage and port terminals, harmonizing to some extent the work done by employees within the Construction Division and other branches of the Army service.

Colonel Shelby—Contracts Division

Colonel Evan Shelby, chief of the Contracts Division, was admitted to the bar of New York in 1896. He practiced law from 1898 to 1906, when he formed a partnership with R. C. Taylor. Since 1912 he has practiced alone, and for four years was New York attorney for the Panama Railroad. He is a member of the Bar Association of the City of New York. He was born in Fayette County, Kentucky, in 1872, was graduated from Kentucky University in 1893, and obtained the degree of LL.B. from the University of the State of New York in 1896.

Upon his entry into the service he was made legal adviser to the Cantonment Division, and was made chief of the Contracts Division in June, 1917. He has had charge of drafting contracts and bonds and also all matters relating to insurance, fire casualties and workmen's compensation.

Colonel Willcutt—Materials Division

Col. Joseph N. Willcutt, chief of the Procurement Division, was born in Cohasset, Mass., in 1875, and was graduated from Harvard University in 1898. Before becoming an Army officer he had been in the construction business, with offices in Boston, doing construction and engineering work. He entered the Army service during the Spanish war in 1898, in the Quartermaster Corps, and during the Texas mobilization for protection against Mexico was camp quartermaster, with the rank of major. He held that rank when he entered the United States service in July, 1917.

Since becoming connected with the Construction Division he has been assistant to Colonel Whitson, in charge of construction of the National Guard camps, and after eight months was put in charge of the Procurement or Materials Division of the Army.

When he joined the division he was president of the L. D. Willcutt & Sons Co. of Boston, Mass.

Colonel Junkersfeld—Building Division

Col. Peter Junkersfeld, chief of the Building Division, before entering the service was, successively, assistant mechanical engineer, electrical engineer, and assistant vice president of the Commonwealth Edison Co., Chicago. He was president of the Association of Edison Companies, with supervision of, or doing consultant work in, contracting, engineering, construction and operation, including allied interests having electric, gas, railway, heating, ice-making, and other utility properties in several states. Colonel Junkersfeld was born in Sadorus, Ill., in 1869, and was graduated from the University of Illinois in 1895, taking the degree of electrical engineer at that university in 1907.

Since joining the division he has been associate officer in charge of the Building Division, obtaining requirements, authorizations, and funds for projects, directing the constructing forces in the field and advising on the commercial relations of the Construction Division.

(*Continued from page* 208)

Colonel Whitson—Building Division

Col. M. J. Whitson, assistant to chief of the Building Division, was born in Le Claire, Iowa, in 1878, and was graduated from the University of Illinois in 1902. Before entering the service he was in charge of construction work for Stone & Webster in the Northwest. Seven years ago he joined Grant Smith & Co. on a partnership basis, and later as director in the corporation. He resigned from this concern in June, 1917, in order to become an Army officer.

In the service he helped organize the Cantonment Division and was in charge of the Construction Branch, which was changed to the Building Division when the Construction Division of the army was organized.

Colonel Hartman—Maintenance and Repair

Col. C. D. Hartman, now in charge of the Maintenance and Repair Division, was born in Brookhaven, Miss., in 1886. He was graduated from the United States Military Academy at West Point in 1908, and was assigned to duty with the Third Infantry, Spokane, Wash., for eight months, thence transferred to Seattle in February, 1909, where he remained until July of the same year. He served in Jolo, Philippine Islands, until March, 1912, under General Pershing, during the clean-up of the southern islands.

After being relieved from duty in the Philippines he was stationed at the Madison Barracks, New York, until May, 1916, when he was sent to the border and stationed at Eagle Pass, Tex., until May, 1917. He was then again detailed to the Madison Barracks, in the first officers' training camp. In October, 1917, he was detailed to the Construction Division, and in March, 1918, was made lieutenant colonel and placed in charge of the Maintenance and Repair Division. He was made colonel in June, 1918.

Colonel Alexander—Administrative Division

Col. J. H. Alexander, chief of the Administrative Division, was born in New Haven, Conn., in 1884, and is a graduate of the University of Minnesota and of the Case School of Applied Science. Before entering the service he had wide experience in construction and engineering work as chief engineer of the Municipal Traction Co. of Cleveland, Ohio; assistant general manager of the Pittsburgh Railway Co., Pittsburgh; chief engineer of the City Street Railway Co. of Cleveland, and assistant to the president of the Cleveland Railway Co., Cleveland. In these positions he has handled all phases of engineering construction, management, and administration of large public utilities, and obtained a broad experience in labor and transportation matters.

The Administrative Division establishes and lays down the fundamental standards and policies for the general administration of the division, approves all labor rates, and supervises labor matters and conditions at all projects. In addition, it compiles and keeps a record of labor rates, conditions and agreements, also records of officers assigned to duty with the division, and supervises clerical routine, files, mail and messenger service, and conducts a general information bureau.

Colonel Neville—Accounting Division

Col. Charles Neville, chief of the Accounting Division, was born in New York City in 1875. Before entering the service he was traffic manager of the Stillmore Airline Ry., general freight and passenger agent and auditor of the Coast and Piedmont Ry., vice-president of the Brinson Ry. (now the Savannah & Atlantic Ry.), and subsequently practiced as a public accountant in Savannah, Tampa and Birmingham. He was senior partner of Neville, McIver, Barnes & Co., certified public accountants, and member of the American Institute of Accountants.

In the service he had full charge of policy, organization, commissions, civilian personnel, requests for commissions, travel orders, etc., and acted for the chief of the Construction Division in all accounting matters.

Rainfall and Run-off Committee Appointed

A committee on the standardization of rainfall and run-off measurements was created at a recent meeting of the New England Water-Works Association. The chairman of the committee is William T. Barnes, of Metcalf & Eddy, 14 Beacon St., Boston, Mass. The other members are Robert E. Horton, Albany, N. Y., who suggested the creation of the committee; George A. Carpenter, Sidney K. Clapp, George H. Leland and John L. Howard. A paper on "Measurements and Records of Rainfall and Snow" will be presented by Mr. Horton at the meeting of the association to be held in Boston Feb. 6.

Work Resumed on Welland Canal

Construction operations on the new Welland Canal, which shut down some years ago on account of the war, have been resumed, according to information from the Canadian Department of Railways and Canals. Work is to be taken up at once on Secs. 1, 2, 3 and 5 under a temporary arrangement with the former contractors. These contractors, with their locations, are as follows: Sec. 1, the Dominion Dredging Co., Ltd., Ottawa; Sec. 2, Baldry, Yerburgh & Hutchinson, Ltd., St. Catherine's; Sec. 3, Doheny, Quinlan & Robertson, Montreal; Sec. 5, the Canadian Dredging Co., Ltd., Midland, Ont.

Supreme Court Upholds Ohio Conservancy Act

In a decision on a taxpayer's action against the Miami Conservancy District directors, the United States Supreme Court recently affirmed the constitutionality of the Ohio Conservancy Act, which had been attacked.

The suit was brought in the form of an injunction to restrain the directors from collecting assessments against the property of the plaintiff, W. P. Orr, and other persons in Piqua, who had been declared to be benefited by the construction of the flood-control work. In the United States District Court of Southern Ohio the case was decided against the plaintiff, and the Supreme Court's decision now disposes of the matter finally. It affirms specifically the legality of taxation and expenditures for conservancy purposes within the Miami district. According to the Miami Conservancy *Bulletin* of January, this was the final step in the litigation instituted against the construction of the Miami River flood-protection work.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN WOOD PRESERVERS' ASSOCIATION; F. J. Angier, Mt. Royal Station, Baltimore, Md.; Jan. 28-29, St. Louis.

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

AMERICAN INSTITUTE OF MINING ENGINEERS; 29 West 39th St., New York City; Feb. 17-20, New York.

The Cleveland Engineers' Veteran Corps has recently been organized by veteran members of the old 10th Ohio Engineers, which afterward became the 112th Engineers, under Col. John R. McQuigg, and saw service on the Western front. Charles Ollenbacher is temporary chairman and Edward Baxter is secretary.

The American Water-Works Association's nominating committee has named the following candidates for office for the year 1919-20: For president, Carleton E. Davis, Philadelphia; for vice-president, M. L. Worrell, Meridian, Mass.; for treasurer, James M. Caird, Troy, N. Y.; for trustees, District No. 1, W. H. Randall, Toronto, Ont.; District No. 2, F. C. Jordan, Indianapolis, Ind.

The Engineers' Society of Milwaukee held its regular monthly meeting Jan. 15 under the auspices of the Milwaukee

Section of the American Society of Mechanical Engineers. Maj. Henry L. Dale, Corps of Engineers, U. S. A., spoke on "Engineering Experiences at the Front."

The Illinois County Superintendents of Highways will meet at Springfield Feb. 13-15. The short course in highways engineering at the University of Illinois will be held at Urbana Feb. 17-22 in connection with the Springfield meeting. The course is open to any one without examination, and there are no charges. The State Highway Department is giving its coöperation and a number of its engineers will appear on the program.

The North Dakota Society of Engineers will hold its annual meeting at Valley City, Jan. 30-31. E. J. Thomas of Minot is president of the society and E. F. Chandler, of the University of North Dakota, is secretary.

The Kansas Engineering Society will hold its annual meeting at Topeka Jan. 30-31. Con M. Buck, division engineer, Santa Fé Ry., is president of the society and Lloyd B. Smith is secretary.

The Engineers' Club of Trenton will hold a meeting this evening to discuss a plan for acquiring permanent quarters of the club, the policy of the club during the coming year on civic matters, and the matter of an American international submarine cable system as a necessary adjunct to the development of foreign commerce.

The Montreal Branch of the Engineering Institute of Canada held a meeting Jan. 16, at which the following papers were read: "Design and Construction of Reinforced-Concrete Viaducts on the North Toronto Subdivision, Canadian Pacific Ry.," by B. O. Eriksen and S. H. Deubelbeiss, and "Some Problems of National Reconstruction," by W. F. Chipman. A meeting of the branch will be held this evening, and will be addressed by J. A. Burnett on a "Coaling Plant for Locomotives" and by George K. McDougall on "Industrial Illumination." A meeting, to be held Jan. 30, will be devoted to fuel problems; Paul Seurot will speak on "Coal Briquetting" and the R. E. Cleaton Co. will show a motion picture entitled "Coal Is King."

The South Dakota Society of Engineers and Surveyors will hold its annual meeting at Mitchell Jan. 28. R. E. Easton, of Aberdeen, is secretary of the society.

The Engineers' Society of St. Paul elected the following officers at the meeting held Jan. 13: President, W. C. Armstrong, chief engineer, Union Depot Co.; vice-president, E. V. Willard, drainage engineer of Minnesota; secretary, Paul C. Gauger, engineer and superintendent, George J. Grant Construction Co.; treasurer, George L. Nason, landscape architect.

The Rochester Engineering Society will be addressed Jan. 24 by S. M. Day, of the General Railway Signal Co., who will speak on "Elements of Alternating Current Signaling." The society will hold a meeting Jan. 27, before which Isaac Adler will read a paper on "A League of Nations."

The Engineers' Club of Philadelphia will be addressed by P. H. W. Ross, president of the National Marine League, on "Public Participation in Maritime Development," at the weekly luncheon of the club to be held Jan. 28.

The Springfield Engineers' Club, Springfield, Ill., elected the following officers at the recent annual meeting: President, H. B. Lewis; vice-president, J. Leisenring; secretary, D. A. Henry.

Personal Notes

Readers who are returning to civil life from military, naval or other Government service are strongly urged to send in items about themselves and about their friends who are in similar situation. Items should give former position, describe character of military or other service and state the civil work to which the engineer or contractor in question is going. In the case of those with service abroad, information regarding the activities of the units to which they were assigned is especially desired.

COL. WILLIAM J. WILGUS, Corps of Engineers, U. S. A., deputy director general of transportation with the American Expeditionary Forces in France, has returned to this country. Colonel Wilgus was formerly vice-president and chief engineer of the New York Central & Hudson River R.R., and before entering the Army had been in consulting practice in New York City.

LIEUT.-COL. A. S. CUSHMAN, who, for 18 months, was in charge of metallurgical and explosives investigations for the Ordnance Department at the Frankford arsenal, has been discharged from the Army and has returned to Washington to assume the directorship of the Institute of Industrial Research, Incorporated.

D. W. MURPHY, drainage engineer, United States Reclamation Service, Los Angeles, has resigned to engage in private practice as consulting engineer, with office in the Hollingsworth Building, Los Angeles, specializing in irrigation and drainage and the care and protection of soils. He has been connected with the Reclamation Service since 1904 and was appointed drainage engineer in 1911.

CHARLES W. STANIFORD has resigned as chief engineer of the Department of Docks and Ferries of New York City to enter consulting practice in dock, port and harbor work. He will be located at 50 Church St., New York, in the same office as B. F. Cresson, with whom he is associated at present in a number of port and harbor studies. Mr. Staniford has been in the dock department of New York for 30 years and has been chief engineer 14 years. In that time he has had charge of such well known dock construction as the Chelsea development on the West Side and the deep cofferdam at the 47th St. piers, also on the North River. During the war he was a member of the committee on port terminals of the Council of National Defense, which planned the storage and terminal facilities for the overseas shipments to the troops in France. He also made the appraisal in 1918 of the German dock property in Hoboken.

MAJ. GEORGE SYKES, Corps of Engineers, U. S. A., has returned to the United States from service overseas and will reëngage in business in New York as head of the George Sykes Co., specialists in the building of country houses. Major Sykes was, until July 1, 1918, executive officer for the chief engineer of lines of communication, and was then placed in charge of the construction of cantonments in rest areas for the advance section.

CAPT. CHARLES F. HEALEY, Corps of Engineers, U. S. A., who was division engineer on the northwest lines of the American railroads of the American Expeditionary Forces in France, has returned to the United States and has been discharged from the Army. He is at present at his home in Goshen, Ind.

A. W. THOMPSON, Federal manager of the Baltimore & Ohio R.R. and associated lines east of Parkersburg and Pittsburgh, has tendered his resignation to the Government, to become president of the Duquesne Light Co. of Philadelphia, and the Philadelphia Co., the public service company of that city. Mr. Thompson was previously chief engineer of the Baltimore & Ohio, and in 1912 was appointed vice-president in charge of operation and afterward vice-president in charge of traffic and commercial development. He became Federal manager of the system last year. He was graduated from Allegheny College in 1897 and entered the service of the Baltimore & Ohio in 1899 as assistant engineer of surveys on the Pittsburgh division. A year later he was

appointed division engineer of the Pittsburgh division. In 1903 he became superintendent of the Cumberland division and later of the Wheeling division. In 1907 he was appointed chief engineer maintenance of way, becoming chief engineer three years later. It is expected that Mr. Thompson will assume his duties as president of the Philadelphia Co. in February.

MAJ. R. S. BUCK, 11th Engineers, U. S. A., has returned from France and has received his discharge from the Army. He will resume his position as engineer maintenance of way of the New York Railways Co.

JACOB LOUIS JACOBS, who has been engaged on special staff work for the United States Shipping Board, Emergency Fleet Corporation, has returned to his work as head of J. L. Jacobs & Co., industrial engineers, Monadnock Building, Chicago.

MORRIS L. COOKE, BOYD FISHER, KEPPELE HALL, HORACE K. HATHAWAY, CLYDE L. KING and JOHN H. WILLIAMS have become associated as consulting engineers in management, with offices in the Finance Building, South Penn Square, Philadelphia.

COL. WILLIAM B. LADUE, 207th Engineers, U. S. A., who recently returned from France, has been appointed district engineer, Delaware River and Bay district, with headquarters in the Witherspoon Building, Philadelphia. He was previously in charge of the Contract Division of the War Department, with the rank of major, and in 1913 was placed in charge of the river and harbor improvements at Jacksonville, Fla.

JOSEPH MELTZER, previously engineer, Casper Ranger Construction Co., Boston, and lately resident manager, United States Housing Corporation, Quincy, Mass., has organized the firm of Joseph Meltzer & Co., engineers and contractors, with office at 31 Beach St., Boston, to engage in general contracting work, specializing in the construction of paper mills and other industrial buildings.

LIEUT. FRANCIS W. DU BOIS, Sanitary Corps, U. S. A., who has been stationed at Selfridge Field, Michigan, as camp sanitary engineer for the past five months, has been discharged from the service and will resume the practice of civil and municipal engineering at an early date. He was previously a member of the firm of Cory and Du Bois, Inc., engineers, Baker, Mont.

H. LOU MILLER, formerly engineer with the duPont Engineering Co., on the construction of the power plant at Nashville, has entered the service of the Portland Cement Association, at Kansas City, Mo.

O. W. CHILDS, senior highway engineer and highway bridge engineer, Bureau of Public Roads, Washington, D. C., has removed to Denver, to become superintendent of the Denver Steel & Iron Works. In 1890 Mr. Childs entered the employ of the Chicago Bridge & Iron Co., remaining in structural work until he entered the Bureau of Public Roads five years ago.

LIEUT. WILLIAM P. DANFORD, 139th Engineers, U. S. A., has received his discharge from the service and has returned to the Oklahoma State Highway Department as district engineer, in which he previously served as assistant state engineer.

R. A. MILLER, F. D. HOLBROOK, and W. D. P. WARREN have become associated under the firm name of Miller, Holbrook, Warren & Co., civil engineers, Decatur, Ill., combining the firms originally known as the Miller-Holbrook Engineering Co. and the Warren Engineering Co. The new firm will specialize in general municipal improvements and reinforced-concrete structures.

HARRISON GRAY OTIS, city manager of Auburn, Me., has resigned to become associated with the American City Bureau, with office in the Tribune Building, New York City. Mr. Otis is secretary of the City Managers' Association.

MAJ. LEWIS E. MOORE, Corps of Engineers, U. S. A., who was in charge of heavy highway bridge work with the American Expeditionary Forces in France, has returned to the United States and has received his discharge, reassuming his connection as engineer of the Massachusetts Public Service Commission.

F. J. WALSH, consulting engineer, Astoria, Ore., who was engineer of sewer construction at Camp Lewis, has been appointed consulting engineer of the Port of Tacoma, Wash., in the development of plans for harbor improvements.

MAJ. MURRAY BLANCHARD, 520th Engineers, has returned from France and has received his discharge from the service. He was formerly connected with the Sanitary District of Chicago.

JAMES A. BUTLER and F. ALBERT HAYES have become associated under the firm name of Butler & Hayes, Inc., experimental engineers and mechanical and chemical consultants, with office and laboratories at 220 Devonshire St., Boston.

JOHN M. MALANG, superintendent of the special road district, Joplin, Mo., has been appointed secretary of the Missouri State Highway Commission.

OBITUARY

ROLLA C. CARPENTER, professor emeritus of experimental engineering, Cornell University, died at his home at Ithaca, Jan. 19. He was born in 1852, and was graduated from the University of Michigan in 1877, after which he served for one year as assistant engineer on the construction of the Detroit & Bay City R.R. From 1878 to 1890 he was professor in charge of the department of mathematics and civil engineering, Michigan Agricultural College. In 1890 he became associate professor of experimental engineering and was in charge of that department at Sibley College, Cornell University. He had engaged in a considerable amount of consulting engineering work, particularly in the installation of water-supplies.

GEORGE SHERWOOD HODGINS, editor of *Railway and Locomotive Engineering*, died in New York, Jan. 18, at the age of 59. He was born in Toronto, and for a number of years was mechanical engineer of the Canadian Pacific Ry. He went to New York about 20 years ago and since then served as an editor of *Gas Age* and *Railway Age*, later becoming associated with *Railway and Locomotive Engineering*, with which he was connected for 15 years.

CHARLES E. VOGDES, engineer, Second District of the Highway Bureau of Philadelphia, died in that city Jan. 12. He entered the service of the Park Commission of the city in 1894 and in 1901 was appointed one of the highway commissioners who later were succeeded by the district engineers in the Highway Bureau.

FREDERICK BROOKS, past president of the Boston Society of Civil Engineers, died in Boston Jan. 10. He was graduated from Harvard in the class of 1868 and afterward took a course at the Massachusetts Institute of Technology. Besides his work in this country, he was at one time engaged on the construction of the Mexican Central R.R. For several years he was secretary of the Association of Engineering Societies, acting also as editor of the *Journal* of the association.

BERNT BERGER, consulting engineer, New York, died in that city Jan. 16. He was born in Norway in 1866 and came to this country in 1886, becoming associated with Theodore Cooper, under whom he served for some time as assistant engineer on various bridge and railway projects. He was engaged in the construction of the Mexican National Ry. shops at Laredo, Tex. Mr. Berger was a past president of the Brooklyn Engineers' Club.

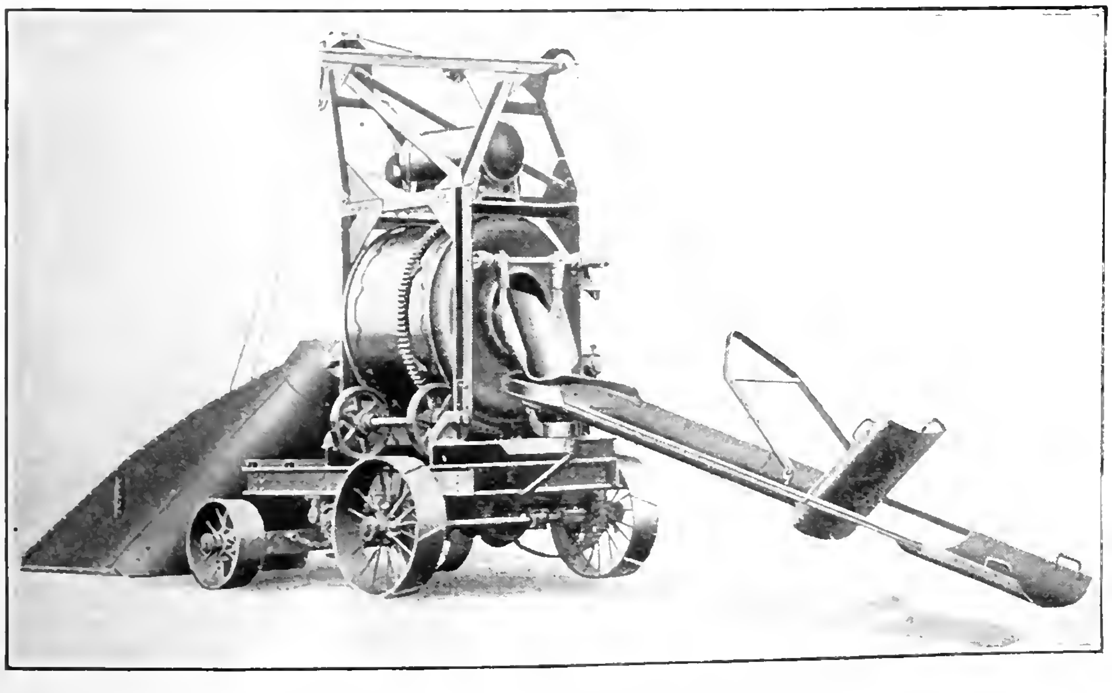
Dunn Wire-Cut-Lug-Brick Patents Are Sustained

The Dunn Wire-Cut-Lug Brick Co., of Conneaut, Ohio, was sustained by the United States Circuit Court of Appeals of the Sixth District in its suit against Joseph Nicholson et al, of Toronto, Ohio, for infringement of its patent number 918,980 dated Apr. 20, 1909, on wire-cut-lug paving bricks. The court affirmed the validity of the patent, declaring it basic and requiring a discontinuance of manufacture and an accounting by the defendant.

The suit grew out of the making and selling by the defendant of wire-cut brick having lugs cut with a knife instead of wires. In rendering its decision the court held that the Dunn brick was a new and useful invention; that its wide, general use aided in establishing its character; that it was an improvement on other wire-cut brick, and was produced by simple means; that the invention was protected by a basic patent, and that the method of cutting the lugs made no difference, since, whether the cutting be done by wire or knife or saw, the methods are equivalent, and the Dunn company is entitled to protection.

Paver That Can Be Used in Alleys as Well as in Streets

A concrete mixer and paver of a new design in which larger capacity is attained without sacrificing compactness, is shown in the accompanying illustration. It is adapted to work in alleys and other tight places as well as to the usual street work. It is 7 ft. 3 in. wide and 14 ft. 4 in. long, with loader down as shown, but without spout. Its height is 11 ft., allowing ample head room for the ordinary bridges and viaducts. It is self-propelled at speeds up to 1½ miles per hour, and has a capacity of 10, cu.ft. dry material per batch, or 8 cu.ft. wet mix. The distributing spout swings in 180° limits, has adjustable pitch and is provided with gates for discharging the concrete in three places. It is manufactured by the Lansing Co., Lansing, Mich.



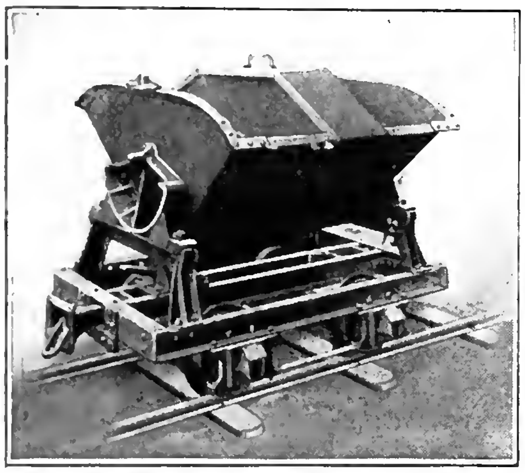
PAVER FOR USE IN RESTRICTED AREAS

Material-Handling Machinery Makers Form Association

Manufacturers of material-handling machinery met in New York Jan. 15-16 to organize an association to promote the development of their products. A temporary organization under the leadership of James A. Shepard, of the Shepard Electric Crane & Hoist Co., was effected. It is expected that the permanent association will be complete in a few days.

Car Measures Correct Amounts for Concrete Mix

A 1-yd. tram car has been designed to hold and convey complete and properly proportioned quantities of concrete material from a central storage or loading plant to the concrete mixer. After the car is loaded with sand and stone it is run past the cement shed where the cement box, which is water-tight,



CAR FOR CONCRETE INGREDIENTS

is filled, either with bulk or bag cement. This makes possible the use of bulk cement on the job exclusively, but if bag cement is used the cement compartment may be employed to return the salvaged bags to storage. When the cars reach the mixer the body is lifted off the running gear, and the complete batch is dumped into the charging skip of the mixer. The cement box is removable, making the car a 1-yd. V-dump, and the entire body may also be removed from the truck, thus converting it into a flat-car on which forms, track or other material may be hauled. The car is manufactured by the Lakewood Engineering Co., Cleveland, Ohio.

Business Notes

Walter Snyder, former associate of Frederick A. Waldron, has formed a partnership with Addison G. McKean, under the firm name of Snyder & McKean, industrial and consulting engineers, with offices in the Kinney Building, Newark, N. J.

H. W. Clarke, who was until recently connected with the advertising department of the McGraw-Hill Co. in Chicago, has been appointed manager of advertising for the Chicago Pneumatic Tool Co., Chicago. Mr. Clarke has been identified with the engineering advertising field for several years.

The Whiting Foundry Equipment Co., Marquette Building, Chicago, Ill., whose general office and works are at Harvey, Ill., announces that Samuel Moore, formerly general manager of the Bond plant of the American Radiator Co., succeeds F. A. Rundle as general superintendent, and E. V. Brown and Walter R. Hans, of the company's engineering staff, will be attached to the Chicago office of the company.

First Lieut. C. F. Messinger, chemical warfare section, stationed at Camp Kendrick, Lanehurst, N. J., has been mustered out of service and has returned to his former position as manager of the sales department of the Chain Belt Co., Milwaukee.

Trade Publications

"Steel Tile Forms" is the title of bulletin 12A issued by the Northwestern Iron Works of Eau Claire, Wis., incorrectly noted in *Engineering News-Record* of Jan. 2, p. 70, due to a typographical error.

"Jeffrey Bucket Elevators" is the title of catalogue No. 244, issued by the Jeffrey Mfg. Co., Columbus, Ohio. The book contains 40 pages, illustrated by half tones and line cuts, and gives other information regarding the styles used in handling materials of all kinds. The book is in pamphlet form, 8½ x 11 in., making it convenient for filing in ordinary letter files.

Waterworks

PROPOSED WORK

Mass., Danvers—Town applied to State Legislature for authority to borrow $200,000 to rebuild and relay watermains, improve storage, pumping and distributing facilities.

Mass., Fitchburg—City applied to State Legislature for authority to borrow $300,000 to extend present water-works system. F. H. Foss, mayor.

Mass., Watertown—(Middlesex P. O.)—Metropolitan Water & Sewer Comn., Ashburton Pl., Boston, asked State Legislature for authority to issue $115,000 bonds to build mains, pipe lines, conduits, etc., and provide additional water supply from southern high service for Watertown and Belmont Twps.

Md., Princess Anne—Town Comrs. plan to build water distribution system including 1 or more wood stave tanks, installing gasoline pump and laying terra cotta and c.i. pipe. About $60,000. C. Laukford, pres. L. J. Houston, Fredericksburg, Va., engr.

Minn., St. Paul—City plans to build 7 mi. concrete conduit 7 ft. diameter, to carry water from Lake Vadnais to McCarron Lake. About $300,000. O. Claussen, city engr.

Kan., Hiawatha—Comrs. Brown Co. having plans prepared for new water supply pump house, pumps and about 2 mi. pipe and transmission lines. About $25,000. Black & Veatch, Interstate Bldg., Kansas City, Mo., engrs. Noted Dec. 26.

Okla., Miami—City plans to build rein.-con. reservoir, 12 x 85 x 145 ft. deep with 1,500,000 gal. capacity. R. Q. James, city clk.

Ore., Astoria—Capital Issues Com. granted permission to Astoria Water Comn. to sell $50,000 bonds to complete high service reservoir. A. Johnson, supt.

Cal., Hayward—City retained Olmsted & Gillelen, engrs., 1112 Hollingsworth Bldg., Los Angeles, to prepare plans and submit estimate for water works system.

Cal., Pittsburg—City retained Olmsted & Gillelen, engrs., 1112 Hollingworth Bldg., Los Angeles, to prepare plans and submit estimate for water works system.

Cal., Sacramento—City election Apr. 30, to vote on $1,200,000 bonds for water filtration plant. F. C. Miller, city engr.

Ont., Peterborough—Utilities Comn. purchased site at north end of city and plans to build filtration plant.

PRICES AND CONTRACTS AWARDED

(★Indicates award of contract.)

Mich., Detroit—H. S. Starkey, secy. water comn., 232 Jefferson Ave., received bids Jan. 14, furnishing 1000 tons 6 in. c. i. pipe and 1000 tons 8 in. c. i. pipe, from Amer. Cast Iron Pipe Co., 512 1st Natl. Bank Bldg., U. S. Cast Iron Pipe Co., 122 South Michigan Blvd., J. B. Clew & Son, Harrison St. Bridge. Contractors all of Chicago and each bid $63.60 per ton. Noted Jan. 9.

★**Mich., Wyandotte**—City let contract furnishing and laying 1450 ft. submerged intake pipe and elbows equipped with flanges and joints, removal of existing elbow, relocating existing crib, final testing, dredging and backfilling and all labor and material involving 1450 ft. 24 in. c. i. pipe, to A. Q. Thatcher Constr. Co., 8 Marine Bldg., Toledo, O. About $37,500. Noted Jan. 9.

Sewers

PROPOSED WORK

Conn., Bridgeport—City plans to build sewers in east end section. About $300,000. J. A. McElroy, city engr.

Pa., Scranton—City receives bids in June building sewerage system in 21st Ward. About $165,000. W. A. Schunk, city engr. Noted Aug 15.

Ia., Davenport—City plans to build 400 ft. 66 in. storm drain sewer and 1300 ft. tunnel in Blackhawk Creek Dist. About $100,120. R. E. Sawistowsky, city engr.

Ark., Hot Springs—City soon lets contract building sewers in Sewer Impvt. Dist. No. 40, 6 in. mains, cost, $4200; also in Impvt. Dist. No. 43, 6 and 8 in. mains, $9000. F. A. Stearns, comr.

Tex., Dallas—City plans to build 1300 ft. monolithic concrete and tile pipe storm sewer in Grand Ave., from Oakland to Meyers Sts., cost. $7766; 800 ft. 30 in. rein.-con. sewer in Oakland Ave. from Forest Ave. to South Blvd., $4040; 12,000 ft. 30-60 in. monolithic concrete pipe and 15 to 24 in. tile sewer in Douglas St. Dist., $70,150; 1500 ft. 15-24 in. tile pipe sewer in Fair Park, $8941. G. D. Fairtrace, city engr.

Volume 82 — NEW YORK, THURSDAY, JANUARY 30, 1919 — Number 5

Self-Government of Construction Camps

A NOTABLE experiment in construction camp democracy is outlined on p. 235. Camp rule ordinarily is imposed by the contractor. Instead, on the Miami flood-protection works all affairs pertaining to community life are in the hands of the camp residents. Outside of, and above the community organization, stands the Conservancy District administration, but its authority is imposed only as a beneficent influence for sound self-government. It guards democracy. This undertaking in construction camp self-government promises to create a more stable working organization, to intensify community interest and pride in the basic enterprise, and to make the workman a partner. Contractors should watch the experiment closely.

Will the Railroad Administration Discourage Building?

JUST at this time, when the country is becoming seriously worried over the business inaction which is leaving thousands of men on the street unemployed and threatening bread lines in the near future, comes a movement in the Middle West to increase freight rates on sand, gravel, stone and slag in Central Freight Association territory—the increases for two-line haul running as much as 90 per cent above rates for the same mileage for single-line-haul producers. Hearings are to be held in Chicago on Thursday of this week before C. J. Brister, chairman of the Central District Freight Traffic Committee, and it is hoped that wise counsel, taking into consideration the national interest in the large, will prevail. Freight increases on these vital building materials will still further defer the opening of a large volume of construction work, and on the renascence of the construction industry every thinking man in the United States, from the President down, is pinning his hope that disaster may be averted. The proposed increase is a simple case of loading on to the traffic more than it will bear. At present there is little tonnage in these materials, and there is sure to be less if the rates are increased. From the standpoint of the Government, therefore, which must bear railroad deficits now, it will be better to leave the rates as they are, or even to reduce them, and thus get some revenue in hauling these commodities, than to scare away prospective business by prohibitive rate increases. Moreover, even if there should be some losses at the present, or at lowered, rates, the Government can afford to bear them rather than have the country suffer the serious economic loss which will come from unemployment and its attendant evils. Anything which tends further to discourage construction work is a blow to the country. For patriotic, for sound economic, reasons rates in the Central Freight Association territory should not be disturbed.

Not Only By Their Work Shall Ye Know Them

ENGINEERS have fondly believed that most of the problems that come under that much overworked word "reconstruction," as currently used, are within their province. Certainly, every day is proving that industry and labor will loom larger in the readjustment period than anything else, and who has a more intimate knowledge of industrial conditions and labor difficulties than the engineer? It is, then, disappointing to find in Governor Smith's New York reconstruction commission of 36 men and women only one engineer, and he a man of intense specialization. Business men have nine representatives; bankers, eight; lawyers, four; sociological experts, three, and labor, two. Editors, doctors, farmers, and engineers have one each; the rest are difficult to classify. The distribution is significant of current opinion, for all published comments agree that the Governor has carefully selected an able and representative group. The engineer is in part responsible for this attitude. What a man thinks and does may make little impress on the world at large, unless the world is told of his thoughts and actions. So it is with the engineering profession. Until it becomes vocal, through its individuals and organized societies, the world will consider it a group of master artisans, quite capable of solving the material problems of construction and manufacture and distribution, but subservient to the banker, the business man, and the lawyer in the great science of living.

Little Room for American Endeavor in France

IN THE issue of Jan. 2 *Engineering News-Record* answered the question frequently asked, "Are American engineers and contractors wanted in France and Belgium?" The answer, viewing conditions as they are now, was, emphatically, "No." Following up that answer we are fortunate in being able to present in this issue two articles that go into the French situation more fully—that give the facts as to the extent of the destruction, and discuss the plans for rehabilitation. Mr. Ford, the author of the longer article, has had, in his capacity as head of research for the American Red Cross, exceptional facilities for ascertaining the facts. There could be no higher authority. Mr. Williams, oc-

cupying the position of commercial attaché of the American embassy in France, gets a somewhat different light on the situation. Looking into the spirit of those who are planning the rehabilitation, he reports a disposition to abandon ruins which have been replaced by properties elsewhere in France. On one point he is decidedly specific—that the prospects for getting business for Americans from the devastated zone are not encouraging. Moreover, this idea is conveyed, too, by Mr. Ford's article, when he reviews the ability of France to supply her own building materials. Altogether, it seems advisable for American engineers, contractors and manufacturers who want engagements or business in foreign lands to look elsewhere than in France. While *Engineering News-Record* has not been able to get equally full information regarding Belgium, such word as has come to hand indicates conditions identical with those of France, so far as prospects for American endeavor are concerned.

Have the Railways Used the Engineering Profession Well?

THE engineering profession may justly claim to be the creator of the railway. All its structures and machinery existed in the engineer's brain before they assumed concrete form. Yet there is probably not an industry which has so signally failed to give the engineer proper position and compensation.

The low pay of engineers in railway service has been long notorious. It was prominently brought forward in the statistics of the earnings of engineers in various occupations collected by the American Society of Civil Engineers a few years ago. Elsewhere in this issue detailed figures are given for railway engineers' pay, compiled from the Government's official statistics. The showing is one that may well command the attention of the profession and ought to awaken public interest.

For it is not difficult to establish a relation between the failure of the railways properly to use and reward the engineer and their failure to earn the profits which they should. It is well to recall that famous definition of an engineer as "a man who makes a dollar earn the most interest." That definition was the result of a noted engineer's practical experience in railway work.

There is no claim here that engineers can perform miracles. They cannot prevent the great increase in wage rates and the eight-hour day from producing a huge increase in railway operating expenses. The engineers and draftsmen who are kept doing mere routine work can do very little, admittedly, to help the railways out of the financial slough in which they now lie. But there are engineers in railway service who with proper authority and funds could do a great deal to save money for the railways.

Director General Hines has just announced that $491,000,000 will be spent this year on additions and betterments. This work must be done under the direction of engineers. Has all this work received thorough investigation by competent engineers, so as to insure maximum economy? That the work has been passed on by a board of engineers is doubtless true; but every experienced construction man knows that time and money spent in preliminary investigations will often result in saving ten times the amount in the cost of carrying out the work.

There is no doubt that in many railway companies an engineering organization has been built up which has done able and conscientious work, notwithstanding the handicap of inadequate pay; but it is not fair to the men who render this service nor safe to the railway's financial position to continue to pay less for good service than it is worth. The railway engineer has as good a right to a living wage as the blacksmith or the baggageman and as good a claim to a return on his investment in education and experience.

Sanity In Planning Passenger Terminals

HAVE we arrived at any degree of sanity in the consideration of railway terminal problems? The action at Cleveland, in endorsing by popular vote the railway-terminal project described elsewhere in this issue, puts the problem squarely, not only before the engineers who have dealt with the Cleveland situation, but before the whole profession. The question concerns the larger elements involved in terminal planning, such as location, desirability of centralizing all roads in one station, etc. Moreover, the situation makes opportune a discussion of the justification for exceedingly heavy terminal expenditures.

Briefly, the situation at Cleveland is this: For years there has been agitation for a new station on the lake front, resulting finally in a well matured plan of making the new station fit in with a civic-center development. Then, as out of a clear sky, comes a proposal to scrap these plans of long consideration and to place a terminal to accommodate all roads, and electric interurbans also, in a station adjoining the Public Square. With a hurrah, Cleveland's citizens drop the former plan and approve the new one—despite the declared disapproval of the Cleveland Engineering Society, and the condemnatory import of the report by Col. Bion J. Arnold, engineer to the Chamber of Commerce, on the terminal problem.

Apparently, the points that won the day were the proximity to the Public Square and the union of all railroads and interurbans under one roof. Yet are not these the very reasons why sound planners for a city's future should reject the scheme? The Public Square is already the point of maximum congestion in Cleveland—yet the new scheme would concentrate still more people there. Again, is not the unification of all passenger terminals a fetish too long pursued by terminal planners? It, too, tends toward more severe rather than lessened congestion.

"Convenience to the public demands a single station," is the answering cry. Convenience to how many of the public? For what percentage of passengers is this accommodation allowed to work all manner of inconvenience to every other passenger and to every citizen coming near the congestion-creating union station?

Is it not time to find out how many passengers transfer from road to road, and to balance against the benefit to these strangers the rights of all other travelers and of the city and its inhabitants as a whole?

Finally, is this not the time to challenge the whole idea of $20,000,000 and $40,000,000 and $50,000,000

passenger-terminal projects? Who has studied the operating costs of a number of modest stations, as against one huge central terminal? Who has frankly faced the added capital cost of new lines (property costs and all), to reach the central point? Who has data to show that from the railroads' point of view the huge central station is a profitable business venture?

Rank heresy—so will this be branded. But there is urgent need of new thinking on the whole question of city railroad terminals. There needs to be a new appraisal of all the factors, there needs to be a frank breaking away from previous methods of terminal thought. Above all, there needs to be a spade-calling era in which there will be no mincing of words as to the business aspect of large union stations. If a city demands a great monumental terminal—which may be a monumental white elephant, financially, in an operating way and even to the city, on account of the creation of congestion—let the truth be known, and then, if the city demands this addition to its architectural beauties in order to tickle its civic pride, let it assume the burdens which the plan involves over and above those of a sound business solution of the problem.

If this be heresy, we are glad to be heretical.

Why Not Use Machinery for Snow Removal at Railway Terminals?

AN IMPENDING emergency problem which is likely to be presented to railway officials on short notice at this season is that of handling heavy snow at city terminals and yards. As this is a recurrent problem, it should be studied jointly, and evidently in advance, by the engineering, operating and mechanical departments. Speaking generally, however, there seems to be a continual state of unpreparedness, except for reliance upon old and inadequate methods. Consequently, when heavy snowfalls occur, terminals are likely to be blocked and traffic interrupted, or even stopped in exceptional cases, although on the open road trains may be able to operate with some degree of regularity.

Machinery for snow handling at terminals has not received much attention in the past, but present labor conditions should be an incentive to active consideration of the possibilities of mechanical devices. Man-power is the main factor in the old-time methods, and in former years an abundance of temporary labor has been available. The serious shortage of such labor in the winter of 1917-18 showed the unwisdom of relying continually upon man-power.

Moreover, manual labor is largely ineffective, even when the supply is ample, a fact made evident in some cases last winter. When large terminals were nearly or entirely closed, owing to deep snow, the measures adopted consisted almost entirely of the use of large gangs of shovelers. Crowds of men were to be seen, each carrying his shovelful of snow for some considerable distance to a dumping point between or beyond the tracks, and then returning for another load. Progress was necessarily slow on account of the storm and cold, the heavy clothing of the men, and because they had to tramp through snow and across numerous tracks and obstructions.

Steam-heated pits to receive the snow, with connections to city sewers, are provided in the Chicago station yard of the Chicago & Northwestern Ry., but these apparently are not sufficient for the need. As a rule, the snow is piled in some more or less convenient place where it has to be loaded into cars for removal.

That snow-handling machines would be required only occasionally, and for short periods, has been urged as one reason for failure to develop them. But when snow removal is necessary it is urgent, and the needed machines come into the same category as snow plows, snow fences and other special equipment.

A type of machine that suggests itself consists of a wide continuous chain or belt excavator, carried on an inclined pivoted boom attached to the forward end of a car, and delivering the snow to a horizontal conveyor extended back to load cars placed between the excavator and the propelling locomotive. A frame carried by wheels riding on the track rails would support the outboard end of the boom and would be fitted with flangers to clear the rail heads and so prevent derailment. Flangers in the shape of revolving wire brushes might be less liable to injury at frogs and switches than ordinary flanger blades.

Pilot plows and flanger cars may suffice to keep tracks open during a moderate snowfall, but when a heavy fall buries the tracks these devices become largely ineffective. Bucking plows can rarely be used to advantage at terminal yards, as they cannot be operated at the necessary speed, and there is likelihood of derailment on the numerous frogs and switches, especially when these are clogged with ice and snow. Rotary plows are not often available, and for effective work they need a greater depth of snow than is usually encountered near cities, while throwing the snow to a considerable distance by such a machine might cause greater trouble than the snow blockade.

Freight yards constitute a specially difficult problem, since, with snow drifted under long lines of cars, it becomes almost impossible to get the cars out. If attempt is made to move them with a locomotive there is likelihood of pulling out drawbars, or of derailment by wheels riding up on the snow packed in front of them. Shoveling seems to be the only method practicable for such cases, although it is likely that even this problem might be solved in some simple manner if it were given careful study. Spreader cars may be useful in clearing yard entrances and unoccupied tracks.

Blocked switches cause serious delay where frequent train movements are involved, and both gas and electric heaters for these moving parts have been used to a limited extent. Such installations on the New York Central Railroad were noted in *Engineering News-Record* of Dec. 19, 1918, p. 1120. The total cost, including purchase price and operating cost, is probably negligible, considering the very important result of keeping the tracks open and reducing detention of trains.

Two months of winter are still to be faced on a large part of our railway system, so that there is opportunity as well as reason for the study of this important problem. Surely, the present methods of grappling with it indicate clearly a failure to apply to it the same sort of analytical and constructive study that is generally associated with problems of traffic maintenance.

The Facts on the Devastation and the Present Reconstruction Efforts in France

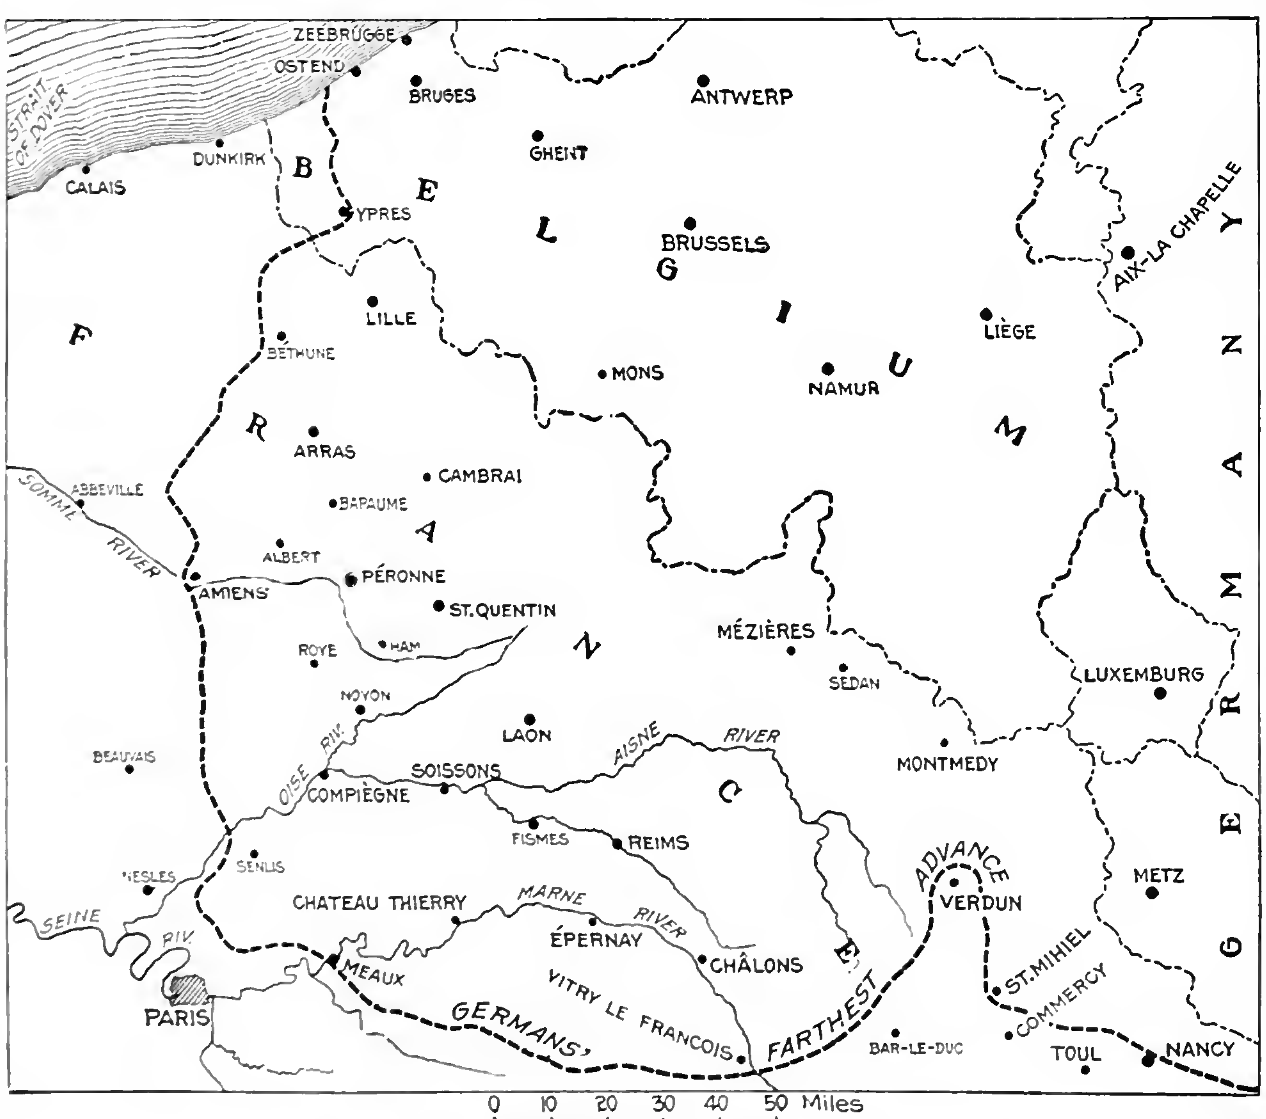
Detailed Summary of the Extent and Character of the Destruction, With a Complete Account to Date of the Measures, Official and Otherwise, to Reëstablish the Invaded Regions

By George B. Ford

Deputy Commissioner of the American Red Cross, Paris, in Charge of Research Work; Formerly Consulting Specialist on Town-Planning, New York City

Further light on the situation in France will be found in the news section of this issue, in the form of a most illuminating interview with Pierce C. Williams, commerical attaché of the American embassy in Paris, who has just returned from France. He answers more specifically the questions regarding trade possibilities and the financial difficulties involved in the rehabilitation work.—Editor.

So stupendous is the destruction in the devastated regions of France that no one can begin to realize what it means. It is only by traveling day after day in an automobile through village after village and town after town, often where nothing is standing erect more than a few feet above the ground, that one can begin to have any conception of its enormousness. The destruction varies much in its completeness. Often where there has been only minor shellfire, one finds just the roofs and the windows gone. Or again, in towns like Vaux or Suippes, that have been through a terrific bombardment, one hardly appreciates that he is passing what was formerly a village, so thoroughly churned up are the buildings and the ground.

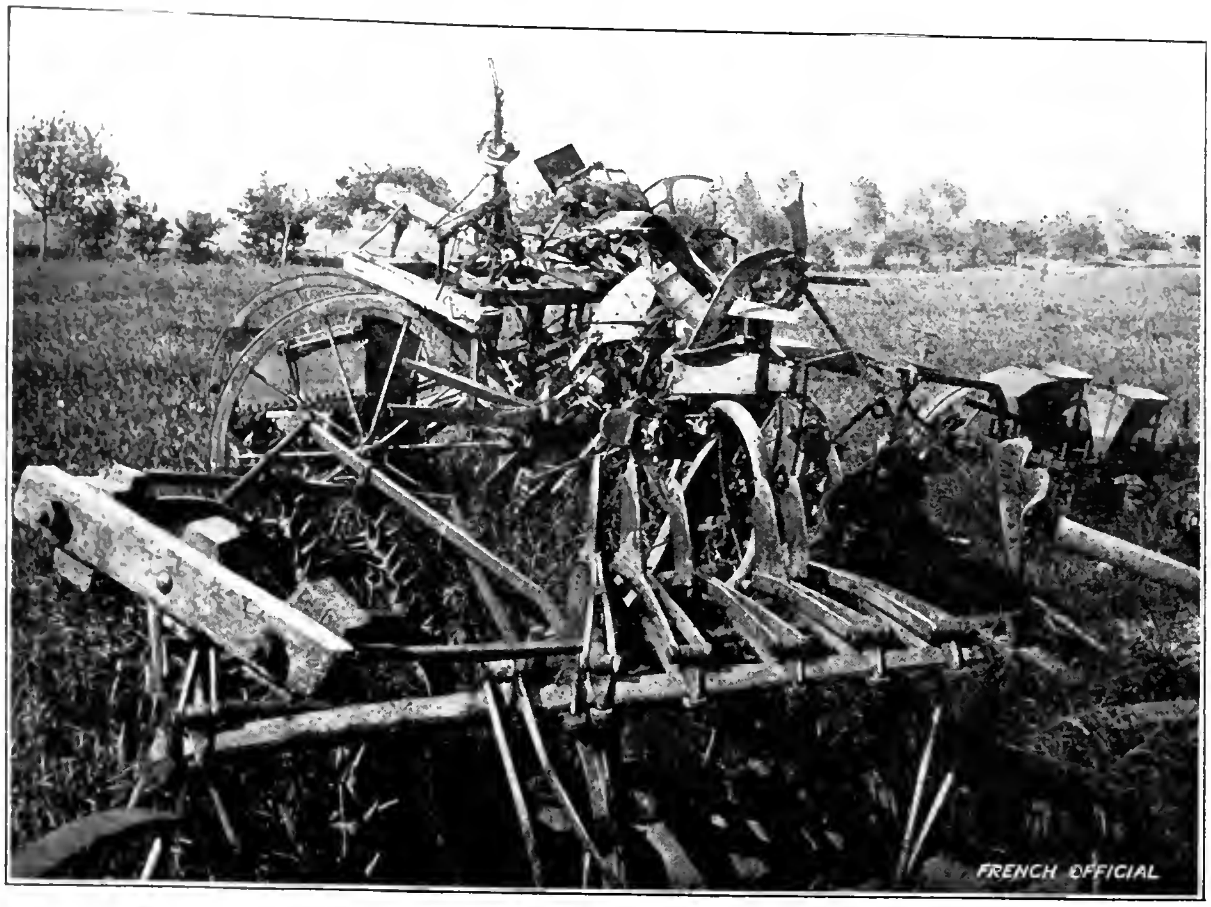


MAP SHOWS DEVASTATED REGION OF FRANCE

In general, where there has been a rapid advance or retreat there has been very little destruction, but where the opposing armies have faced each other for a considerable length of time in one spot the destruction is almost always intense and often complete. For example, in the great German drive of September, 1914, very little destruction was caused, but at the places where the hardest fighting occurred, at the turning of the battle of the Marne—that is, along by Meaux, Sezanne, Vitry-le-François and Revigny—the destruction is quite complete, but only for a narrow fringe where the battle was hardest. The same thing is true along the battlefronts in the Somme and the Aisne, where the hardest fighting took place; there is complete destruction extending over a belt rarely over 10 or 12 miles wide at most.

The other kind of destruction is the wilful devastation by the retreating enemy as in the Somme, the Oise and the Aisne in the spring of 1917. In the first part of the retreat only minor destruction took place, but later he had had time to do a thorough piece of work, with the result that a wide belt east of Peronne, Ham and Noyon was completely destroyed. The same was true in the retreat of the autumn of 1918. It is interesting to see how the destruction developed. For instance, in September, 1914, at the time of the great German advance and during the battle of the Marne, there was comparatively little destruction in the North and in Champagne. It is only when we get down to the Marne, Meuse, Meurthe-et-Moselle and Vosges, that we find the places of any great destruction. In the Marne, 258 communes were damaged, including a total of 3500 buildings entirely destroyed and nearly 12,000 partly destroyed, while 40 communes remained on the German side of the lines. In the Meuse, 59 communes were damaged, with about 1800

buildings completely destroyed and nearly 700 partly destroyed, with 236 communes remaining in the hands of the Germans. In the Vosges, 53 communes were damaged, with a total of 1256 buildings completely destroyed and nearly 2000 partly destroyed, with 25 communes remaining in the hands of the Germans. In the Marne and the Meuse most of the destruction took place during the battle of the Marne, along both sides of the lines, where the fighting was heaviest. It started in at Meaux and did not get really serious until near Sezanne. Then, in the farming villages south of Chalons-sur-Marne and west of Vitry-le-François running up past Revigny and Bar-le-Duc and Verdun and down to St. Mihiel and Commercy, the destruction by shell-fire is intense. This makes a belt about 150 miles long where the destroyed area is anywhere from five to ten miles wide.



AGRICULTURAL MACHINERY WRECKED BY DYNAMITE

Around Nancy there is comparatively little destruction, but north and east of Nancy the destruction is again very serious, almost all by shell fire, including cities like Lunéville, Gerbevillier (which was systematically burned) part of Ramberviller, St. Dié, etc., down to the border of Alsace, where the buildings, especially in the larger town of Thann, are largely destroyed.

In addition, there were various cities behind the lines which were within the range of German guns and in which quite a little destruction has been caused. This is especially true of Belfort, also of Bar-le-Duc, and to a less degree of Nancy.

During the German retreat of March, 1917, in battles of the Somme, the Aisne and the Oise, in the first part of the retreat in the Oise and the Aisne, they destroyed the buildings only partially, usually by burning, so that in most towns the exterior walls and partitions are standing in many buildings; they could be repaired by putting on roofs and putting in windows and doors, but east of the line extending from Noyon to Ham and north of a line extending due west from Ham, the Germans had time to burn systematically and blow up almost all of the villages, with the result that destruction was complete, and in some cases one can ride through a village without knowing it.

Little Is Left of Many Towns

At the time of the German advance in March and in May, 1918, they came within shelling and bombing range of a number of large cities and towns, so that today little is left of Hazebrouck, Béthune, Arras, Albert, Compiègne and Rheims, and severe destruction is seen in Amiens, Clermont, Beauvais, Senlis, Épernay, Chalons, Bar-le-Duc, Toul and Nancy.

In the German retreat, during the last four months in the Somme, Aisne and Oise, a large area southwest of Ham, which before had only been partially destroyed, is now found to be completely destroyed, and cities like Noyon, Ham, Guiscard, Nesle, Roye, Soissons, Dormans and Fismes are almost completely ruined. The devastation in the region around Peronne and Bapaume was so severe before that very little more happened to them.

During the last four months of the war the allies won back from Germany nearly 8050 square miles of land in France, or an area nearly as large as the States of Delaware, Connecticut and Rhode Island. This is nearly 3% of the total area of France, includes about 2000 communes, with a total population before the war of some 2,500,000.

The German advance in March and May of 1918 covered a little over 2300 square miles. The German retreat of March, 1917, covered about 1550 square miles. This was about 80 miles long and had a maximum depth of about 25 miles, making about 0.5% of the total area of France, and including about 500 communes with a total population of about 325,000.

Four years ago the total invaded area exceeded 15,000 square miles, or something over 5% of the area of France, including over 3500 communes with a total population of over 4,000,000, embracing the best manufacturing district and the best farming country of France. This area is larger than Maryland and Delaware combined, or as large as Massachusetts, Rhode Island and Connecticut, or one-third as large as Pennsylvania.

The devastated area in France covers approximately 6000 square miles in all, about 2% of France, with a total population of nearly 2,000,000 people. This is about equal to the area of Connecticut and Rhode Island.

The area reconquered in Alsace until the last phase of the war equalled about 450 square miles, or about two-fifths the area of Rhode Island. Outside of the

half-destroyed town of Thann there was almost no destruction. In all there are about 6000 square miles in Alsace-Lorraine, with 1,874,014 inhabitants in 1910.

Alsace-Lorraine had over 1,000,000 acres of forests. Its chief crops were hay and potatoes. It produced 3,538,722 tons of coal, 20,083,238 tons of iron ore, 102,644 tons of potash. The potash deposits are estimated at 2,000,000,000 tons. It made 2,908,230 tons of pig

EVEN THE TREES AROUND THE RUINED CHATEAU WERE DESTROYED

iron and 1,444,953 tons of steel. There were 5691 textile plants, employing 80,423 persons. These included 1,900,000 cotton spindles.

Belgium has suffered at least $2,000,000,000 worth of destruction in all and there are $2,000,000,000 worth of thefts made and taxes imposed by Germany. Of this amount $1,150,000,000 is loss of machinery, tools and stock. Some 150,000 working men have been taken into Germany.

Belgium covers about 12,000 square miles and had 7,423,784 inhabitants before the war. It had nearly 1,500,000 acres of forest. It produced annually 3,253,067 tons of potatoes, 1,702,535 tons of sugar beets and great quantities of oats, rye and wheat. A total of 22,972,000 tons of coal a year were mined by 145,670 miners and 2,301,290 tons of pig iron were made. There were 1,492,258 cotton spindles in use. In 1913 the Government revenue was $160,000,000 and the total debt $750,000,000.

French Reports on Destruction

On July 24, 1917, the French Ministry of the Interior prepared a report on the destruction, as closely as it could be determined, on the French side of the lines. This report followed one made at the end of May, 1916. The later report covered 1223 communes in 11 departments, whereas the earlier report covered 754 communes in 10 departments. In all these communes there has been more or less destruction, and this number does not include 450 communes that were still too near the front to make it possible to make a complete survey of conditions. The total number of communes freed from the enemy by the advance of the spring of 1917 was 499, thereby reducing the total number of communes resting in the hands of the Germans from 2554 to 2055, all of which are now freed. Most of these communes are strictly agricultural, so that the destruction hits particularly hard the richest farming area of France.

It was reckoned that in the 1223 communes reported on a year ago the number of buildings damaged was 102,697, as compared with 46,263 in May, 1916, and of these the statistics show that in 1917 50,756 of the buildings were completely destroyed. Of the latter, 18,824 were in the Somme and 12,701 in the Aisne.

The hasty investigation since the signing of the armistice shows that *the total destruction in France has been quintupled, with something like 500,000 buildings damaged, of which at least 250,000 are completely destroyed.*

The average cost of these buildings before the war was nearly $5000. As the present cost of a building is about 2½ times greater than it was then, we can say that the total *destruction in France of the buildings alone is today over $6,000,000,000* as estimated by the Government engineers and $4,000,000,000 as estimated by the architects' and contractors' associations.

The total cost of repairing and replacing the *used up or destroyed public works is estimated at about $2,000,000,000* of which $200,000,000 is for the Nord R.R., $150,000,000 for the Est, and $50,000,000 for the other railroads. About $200,000,000 will cover the rebuilding of the canals. The Nord R.R. alone has lost 1731 bridges and 338 stations.

In 1917 there were 527 communes in which over half of the buildings had been completely destroyed. This number has probably reached today something like 1500 communes in all. In 1917 in 400 communes over 80% of the buildings had been damaged, and this proportion probably reaches today over 1000 communes. In the summer of 1917 there were counted over 435 town halls destroyed, 600 schools, 472 churches and 377 other public buildings, and it can be safely said that over 1200 churches are destroyed and over 1500 schools.

Industrial Means of Support of 500,000 Gone

In 1917 were counted over 414 industrial plants destroyed, which supported 105,000 persons. It can probably be said today that there are in all over 1000 plants destroyed, supporting at least 500,000.

On Oct. 25, 1916, a report was made by the Minister of the Interior on the building materials destroyed that would have to be replaced. It was made for 790 communes, or for 41,223 buildings totally or approximately destroyed, and it comprises the destruction of 1,700,000 cu.yd. of stone masonry, 600,000 cu.yd. of brick masonry, 300,000 tons of lime, etc. The largest part of this destruction was in the Pas-de-Calais and the next larger in the Meurthe-et-Moselle. It also showed the destruction of 200,000,000 ft. of lumber, 33,000 tons of iron and steel, 91,000,000 roof tiles and 32,000,000 roofing slates. The total destruction today is probably at least five times as large—which gives a slight idea of the problem before France in reëstablishing this area.

The total loss of furniture and furnishings today, exclusive of machinery, amounts to at least $2,225,000,000 as estimated by the Government engineers and over $1,000,000,000 as estimated by insurance companies.

According to a report made by the *Office de Reconstitution Agricole* to the Minister of Liberated Regions in May, 1918, it was reckoned that at that time about 8000 square miles of French land was in the hand of the Germans. About three-quarters of that area is

tillable and a large proportion of the rest is good for hay or pasturage. This is some of the very best and richest agricultural land in Europe. The 10 invaded and liberated departments produced in 1913 nearly $400,000,000 worth of crops. The average yield of this land is about 32 bushels of wheat to the acre. In the Marne this drops down to about 22 bushels to the acre, and in the Meuse and Meurthe-et-Moselle to about 17 bushels. These regions constitute about 15% of the total tillable area of France, and the crops constitute about 20% of the total for France. The agricultural population here is about 807,000, or about 10% of the working agricultural population of France. It is estimated that *250,000 acres were rendered uncultivable by the war.*

Damage to Farms and Their Contents

In this region there are about 250,000 farms, of which 110,000 are less than 2½ acres apiece and about 100,000 between 2½ and 25 acres. About 26,000 are between 25 acres and 100 acres, and 5500 farms are over 100 acres in size. A great many of these farms belong to people who are working in factories, which accounts for there being such a large proportion of small farms. This is quite unusual in France. The capital investment in these farms is reckoned at $400,000,000, or an average of $1600 per farm. The value of farms has more than doubled in France since the beginning of the war, so the total value of these farms today stands nearer $800,000,000 or $3200 each, without counting the value of the buildings.

To get an idea of the number of agricultural implements that would be needed, a list was made by the Government engineer in charge which showed that to replace the losses they would need about 51,000 side-hill plows, 33,000 other plows, 56,000 cultivators, 30,000 mowing machines, 115,000 farm wagons, 88,000 harrows, 50,000 rollers, 48,000 hoes, 36,000 seed drills, 13,000 fertilizers, 16,000 beet extractors, 21,000 winnowing machines, 18,000 horse rakes, 32,000 reapers and binders, 53,000 root cutters, etc.

With regard to the cattle lost, it is very hard to get at the exact figures, but in these departments in 1913 there were 607,000 horses, whereas in 1915 there were only 242,000, showing a loss of 60%. Of cattle of all kinds there was a loss of 850,000, or 55%, and of pigs the loss was 380,000, or about 55%. The loss in wheat amounts to about 1,300,000 acres and in hay to about 850;000 acres. *The total damage to the soil, to live-stock, crops, forests, tools, etc., is estimated at $2,000,000,000.*

Before the war, France used 59,407,000 tons of coal a year, with 9,166,000 tons more in coke equivalent. Of this France produced about 40,844,000 tons and 5,357,000 tons of coke equivalent. Of the deficiency 27,389,000 tons of coal came from the Valenciennes basin. In all, something over 70% of the total coal supply of France came from the invaded regions, and very much the best quality of coal at that. About 140,000 men were employed in the mines in the invaded regions, out of 203,208 coal miners for all of France. Three-quarters of a million persons were largely dependent on the coal mines. Over $200,000,000 worth of machinery has probably been destroyed.

Before the war the total production of iron ore in France was about 21,918,000 tons, of which 19,629,000 tons came from the Briey and Longwy basins in the Meurthe-et-Moselle; that is, 90% of the total, of which 16,500,000 tons was in the hands of the Germans. The miners who were employed in these invaded mines, with their families, represent at least 150,000 persons out of employment. It is interesting to know that just before the war the total of German iron production was 35,941,000 tons. In the United States it was 63,000,000 tons. Over $500,000,000 worth of machinery has been destroyed, including that of steel and iron mills. Before the war 3,000,000 tons of steel were manufactured in the region invaded by Germany, out of 4,686,000 tons for all of France, or nearly 65%. The same percentage holds for cast iron. The effect of the German invasion on other metals has not been so serious, as most of them come from the interior of France.

The chemical industries have suffered very little from the invasion, proportionally.

The textile industry consisted before the war of about 7,530,000 cotton spindles throughout France, of which 4,500,000 were in the region invaded by Germany and of which almost all were either destroyed or carried back into Germany and France. Out of 2,365,000 wool spindles 2,000,000 were in the invaded districts. Out of 550,000 linen spindles, 500,000 were in the invaded regions and destroyed or removed. The same is true of looms, of which there were 140,000 in France, and over 81,000 of these were in the invaded districts. Over $120,000,000 worth of machinery has been wrecked.

Of 210 sugar refineries in France 140 were destroyed by the Germans, and of 3000 brush factories, 2000 were destroyed. Over $25,000,000 worth of machinery has been ruined. Electric power stations, totaling 300,000 kw. have been destroyed, with an equipment loss of $50,000,000. From breweries over $25,000,000, from machine shops $100,000,000 and from foundries, etc. $60,000,000 worth of machinery is gone. None of these damages includes land or buildings. Furthermore, almost all of this machinery *costs three times as much* to replace today so that it can safely be said that *$4,000,-*

THE FARMER'S CART WAS RUINED

000,000 worth of machinery will be needed to replace that destroyed or carried away. This includes the stock and raw materials damaged and damage done to the mines.

Injury to Cement Plants and Forests

Before the war France manufactured 3,000,000 tons of cement a year. In February, 1918, it was manufacturing only 400,000 tons, which amount since increased and has later diminished through the difficulty of obtaining coal. A large proportion of this was in the invaded departments.

The Service of Forests and Water-Supply in the Department of Agriculture estimates that 1,200,000 acres of forest land have been destroyed by the enemy. Over half of this wooded area belongs to the Government or to the communes. There were about 750,000 acres of woodland within the war zone which have not been cared for since the beginning of the war, and which have thereby lost a great deal of their value. We can count on the complete loss of at least one-quarter of this latter area, or a total loss of nearly 1,500,000 acres. Therefore France has lost nearly 10% of its lumber and 6½% of its firewood. The war has destroyed over two billion board feet of lumber.

Before the war there were about 750,000 men in the various building trades, of whom about 75,000 were located in the invaded departments. The total building done throughout France before the war in any one year was less than 7% of the building that would have to be done to replace what has been destroyed in the invaded departments. Therefore, if no building were to be done elsewhere in France after the war, and reckoning that 500,000 of the building tradesmen of France would be available to work in the devastated regions, it would take over 20 years to rebuild them.

The total damage in the north of France, including that to buildings, agriculture, industry and public works, is estimated at 64,500,000,000 francs, or about $13,000,000,000. These were the figures reported by M. Dubois for the Committee on Budget in the Chamber of Deputies in December, 1918. We have checked most of these figures from various official and private sources, and believe they are somewhat high.

What the French Government Has Done to ReËstablish the Liberated Regions

Early in December, 1914, the French Government, then sitting in Bordeaux, appropriated $600,000 for the immediate assistance of the invaded communes of the Marne. In December, 1914, Parliament incorporated in the budget for 1915 an appropriation of $60,000,000 for the use of the Ministry of the Interior in meeting the most urgent needs of the inhabitants of the region. On Aug. 5, 1918, the Minister of Liberated Regions reported to Parliament that out of this sum, $36,000,000 had been expended, divided by departments as follows: Marne, $3,000,000; Somme, $2,000,000; Oise, $1,500,000; Meurthe-et-Moselle, $1,400,000; the Aisne, $1,300,000; Meuse, $1,000,000; Vosges, $500,000; Seine-et-Marne, $500,000; Nord, $500,000; general supplies, $2,500,000. To this sum should be added $6,000,000 spent to drain out the mines, another $6,000,000 for stocking up with building, industrial and agricultural materials.

In 1916 the Minister of the Interior started a special service to prepare for reconstruction, and in May, 1916, the President of the council created the Interministerial Committee, whose function it was to coördinate the work of reconstruction undertaken by the various ministries. In January, 1915, the Chamber of Deputies adopted a bill known as the *Loi Cordunet* which provides compulsory city planning for the whole of France, particularly the devastated regions. This is not yet law. In September, 1916, the Minister of the Interior asked the *préfets* of the devastated departments to make city plans for their destroyed towns.

Early in 1917 the Minister of the Interior established a fully organized service for handling the interests of the refugees in the devastated regions, and the technical service was organized for repairing damaged buildings and for the manufacturing of demountable barracks. Meanwhile, arrangements were made for giving advances to returning refugees, up to a certain proportion of the eventual indemnity, which they will receive from the state for their damages when the war indemnity bill is passed.

In August, 1917, Parliament passed two laws granting appropriations of $20,000,000 each to the Ministry of Commerce and the Ministry of Agriculture, to make purchases for industrial and agricultural reconstruction. In the autumn of 1917 a special service for reconstruction and for putting the soil back into shape was created in the Ministry of Public Works.

A New Ministry Created

In November, 1917, it became so apparent that there must be a single head and control for all this civilian work in the war zone that the Government created the Ministry of Blockade and the Liberated Regions, of which M. Lebrun is the head. Aside from the work in connection with the blockade, the work in the liberated regions is divided into four main services in the ministry: (1) A general service for the reorganization of general local life, for payment of war indemnities and the coördination of public and private relief agencies, under M. Bluzet; (2) a technical service of reconstruction and putting the soil back into a state for use, under Colonel Suquet; (3) an office of agricultural reconstitution, under M. le Seigneur; (4) an office of industrial reconstitution, under M. de Boisson. Thus, all the different functions of the French Government which have to do with the invaded regions are brought together under one head. Since Nov. 15, 1918, they are at last under one roof at 223 Rue St. Honoré, in Paris.

To the agricultural office was voted a credit of $60,000,000 and a revolving fund of $20,000,000 for its work. To the industrial office was voted a credit of $50,000,000 and a revolving fund of $20,000,000.

The Interministerial Committee continues in an advisory capacity. There is also the parliamentary committee, composed of all the senators and deputies from the invaded departments. This committee keeps a general oversight and legislative and budgetary control over all the Government action for the refugees and their property.

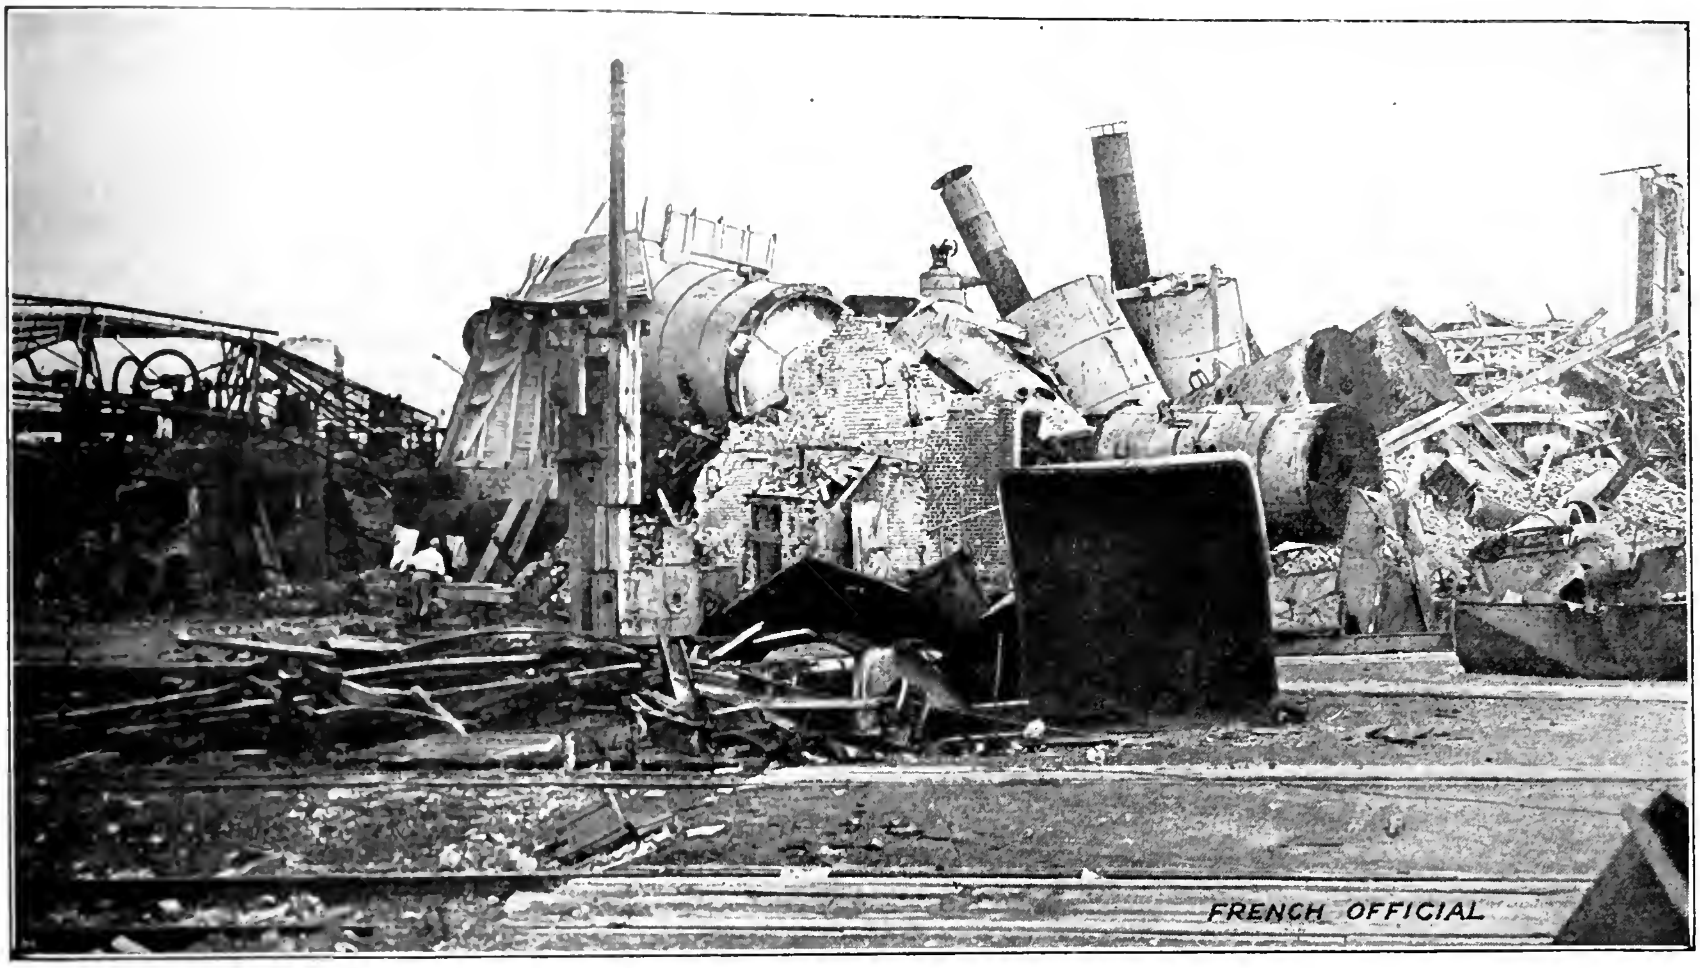
Since the signing of the armistice, the Minister of Armament, with M. Loucheur as minister, has become a Ministry of Industrial Reconstitution, for changing

the munitions plants to peace manufacturing, and absorbing the Office of Industrial Reconstitution from the Ministry of Liberated Regions. A credit of $400,000,000 has been granted to this new ministry.

The Ministry of Liberated Regions has created two new special associates to the minister, a *commissaire général* to act as liaison officer with the other ministries, and a *controleur général* for accounting and follow-up.

In general, the government has (1) been giving immediate aid and relief to the returning refugees, clothing them, feeding them, giving them shelter and the necessary utensils and tools, and (2) it has been helping ate is being considered in the Chamber of Deputies, only one point remaining to be settled, and that is whether the reëstablishment of a business or industry or a home within the same town shall be obligatory or optional, if the damaged person would touch the full indemnity that will be paid to him.

In general, everyone has agreed that every kind of damage should be paid in full, including any extra expenses caused by the increased cost of living, materials and labor. It is expected that this bill will become law within a few weeks. Meanwhile, the Minister of Liberated Regions has been making advances as above



ONE OF MANY SUGAR FACTORIES LEFT IN RUINS BY THE GERMANS

them reëstablish themselves permanently by giving them advances on the indemnities which they will probably receive from the Government, and helping them start the reconstitution of their own livelihood, and helping them to construct the necessary buildings. Mention has already been made of the $34,000,000 distributed for immediate aid, out of a total credit of $60,000,000 voted in December, 1916.

Up to Mar. 31, 1918, $28,000,000 had been advanced to returning refugees against their eventual indemnity, to help them get started in reëstablishing themselves. In addition, about $10,000,000 has been advanced against industrial indemnity. Besides these sums, $12,000,000 has been advanced to the farmers to help them start recultivation of abandoned farm land, out of a total credit available of $3,000,000 granted under what is known as the *Compère Morel Loi* for aiding agriculture in France.

The Government bill providing indemnities in full to those who have suffered full damage was voted by the Chamber of Deputies in 1916. In a somewhat changed form it was voted unanimously by the Senate early in 1918, and at present the version as voted by the Senoted to damaged people who wish to reëstablish their property right away, to the extent of paying them in cash or in kind up to 90% of the appraised value of the property damaged, on the basis of values as they were at the beginning of the war. As the cost of building has more than doubled since that time and almost everything has gone up proportionately, this means that the actual advance is only about two-fifths of what it costs to replace the buildings today.

On Dec. 12, 1918, a law went into effect providing that the state could requisition the piled-up ruins of buildings to work over for new buildings.

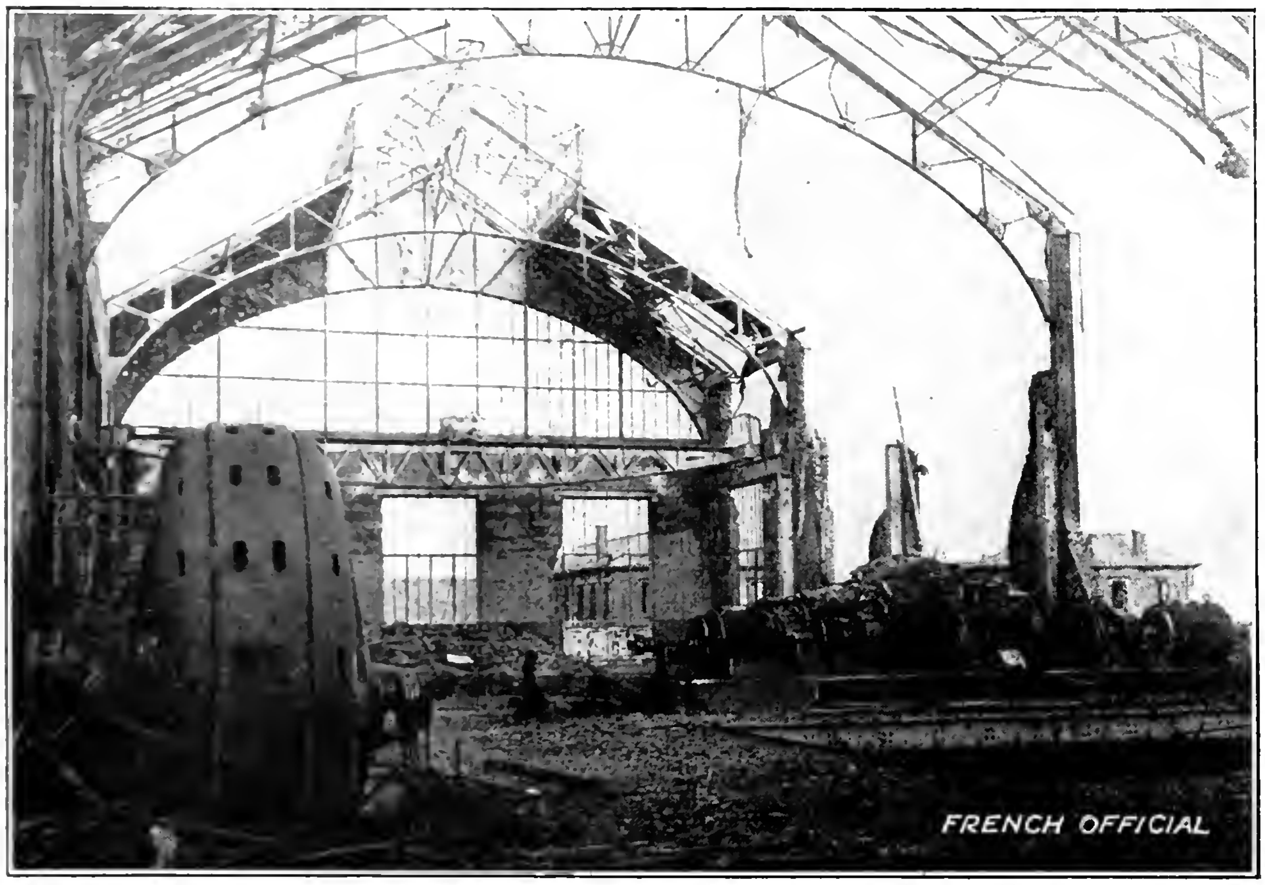
The technical service of reconstruction in the Ministry of Liberated Regions has for the past two years been doing repair work, wherever called for in the devastated regions, working through the local engineers in chief and the Minister of Public Works. It had at work in the Somme, the Aisne, and the Oise, after the German retreat in the spring of 1917, about 1000 German prisoners and 1000 civilians, working under civilian contractors.

Against the eventual indemnities that will be paid, many partially destroyed buildings were repaired and put,

more or less summarily, in a state of use. Almost all of these repairs were in agricultural districts, and the larger part of repairing was on buildings that would house the farm animals, crops, etc. Most of this repair work was wiped out by the German advance in the spring of 1918, but now that the Germans have retreated again and all this area is uncovered this same repair work is starting again.

In the Marne, the Meuse and the Meurthe-et-Moselle, where most of the destruction was caused in 1914, there has been some permanent reconstruction, particularly where the villages are over 30 kilometers from the front. Private contractors, working under the direction of local engineers of public works, have built a number of farm buildings in the region of Meaux and Chateau Thierry and summary repairs have been made to several towns and villages near the front. In 12 or 15 farming villages, south of Chalons-sur-Marne and around Vitry-le-François, the Government has organized coöperative societies for reconstruction. They have grouped almost all the property owners in the village in the society, and, by employing an architect and a contractor in common, they have not only been able to save a great deal of time, money and duplication in the rebuilding of their farm buildings, but they have been able to go to the Government and obtain the service of German prisoners and also to obtain special dispensation from the Army for procuring the necessary lumber, lime and cement, and transportation. In each case they have received the maximum advance on the eventual indemnity for their losses, which has allowed them to rebuild at once about one-quarter of the necessary buildings. In most cases they have started with the grange or grain barn. Over one hundred such have been permanently reconstructed in this region, costing, in all, $230,000.

The technical service of reconstruction has placed orders with private contractors throughout France for about 25,000 demountable wooden houses with two rooms and a shed in each case, costing $700 to $1000 each, and for 10,000 demountable wooden farm buildings, to cost $150 to $800 each.



ALL BUT THE HEAVIEST MACHINERY WAS REMOVED FROM THIS RUINED POWER PLANT IN NORTHERN FRANCE

Between 3000 and 4000 of these had been set up in the Somme and the Aisne and the Oise before the German advance of this spring, all of which were lost. To date, there are between 1000 and 2000 of these demountable buildings either in the newly liberated regions or on their way there, the great difficulty being to secure transportation and the necessary labor for mounting them. Since the armistice, however, the labor problem is being solved rapidly. As to labor, on Aug. 10, 1918, General Pétain sent a general order to the commanders of all divisions, regiments or companies, that when they found themselves located for several days or more in a devastated town or village, they should apply immediately to the engineer in charge of reconstruction work, to see how the soldiers could help either in cleaning up the ruins or putting the roads or water-supply in usable condition, or in doing agricultural work. On Sept. 6, 1918, the Minister of Liberated Regions instructed the local engineers in charge and the mayors of the towns to prepare advance programs of the work that such troops might do, so that no time should be lost. To prepare for eventual full reconstruction, the technical service of reconstruction of the Government is organizing a bureau to purchase building material in advance. It is expected that a credit of $60,000,000 will now be voted to this bureau, $20,000,000 to be available to house and feed workmen in the devastated regions while they are starting reconstruction. Materials and housing will be allocated from the Government storage yards to coöperative groups of contractors according to priority rules.

On Dec. 13, 1918, there was created in the Ministry of War a special service for supplying and setting up temporary barracks wherever needed for workmen or refugees.

Government Supplying Furniture

In July, 1918, the Minister of Liberated Regions asked for bids from private manufacturers on 75,000 articles of furniture, including chairs, tables, cupboards and wardrobes. At the end of August, 1918, it asked for bids on a lot of standardized doors and windows that could be made up ahead, including 20,000 exterior doors, 42,000 interior doors, 37,000 windows and 25,000 shutters. Today it is rapidly increasing these orders, especially to the plants that until the signing of the armistice were manufacturing airplane parts.

With regard to the Furniture Indemnity Law about

to be voted, which provides for paying damages for furniture loss up to $2000, the decree was issued by the Minister of Liberated Regions on Nov. 2, 1918, which allows the individual who has suffered loss of furniture to go out and buy his own furniture with an advance which will be made to him by the state of a sum which must not exceed $200 for the head of the family, and $40 for each other member of the family. If the damaged person prefers, the state will provide him with the furniture out of the stock which it is accumulating.

Virtually all the furniture in the regions which have been overrun by the Germans has been taken back by them into Germany or destroyed. The same is true of utensils, tools, bedding, clothing, etc. In the rich regions of the North of France this furniture was particularly valuable.

Furthermore, the technical reconstruction service is making experiments with building materials that can be found on the spot in devastated regions, and which do not require transportation or special labor for their extraction and preparation, and it is erecting an experimental building in Paris to try out methods of construction, new materials, new types of plans, etc.

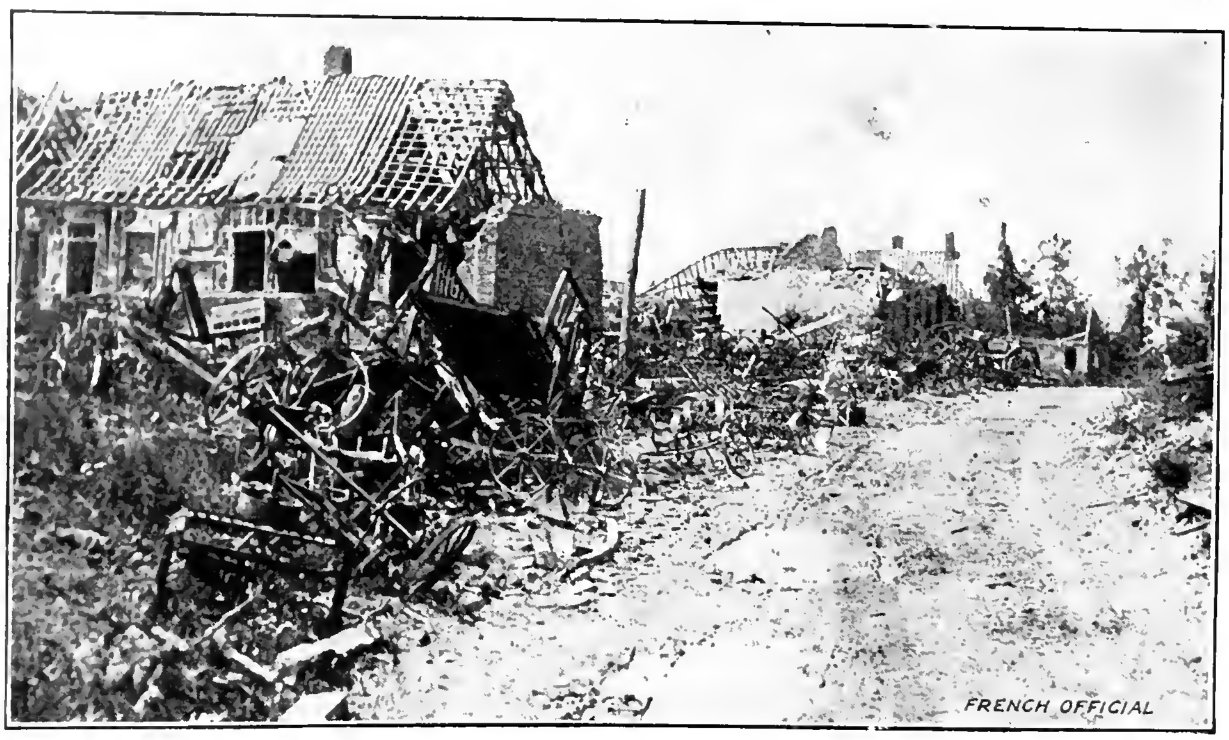
The service published on Oct. 22, 1916, a report showing the distribution of quarries and, in general, the places where the raw building material could be obtained in the individual departments. For example, good building stone can be found in almost all of the departments except the Nord and the Somme. Brick clay can be found in almost all the departments, especially in the North. The only difficulty would be getting the necessary coal for burning the brick. There is plenty of good building sand in all the departments. Cement can be produced in large quantities in the departments of the Pas-de-Calais, Marne, Meuse, and Meurthe-et-Moselle, provided the plants can have the necessary coal and labor. Most of the departments can furnish plenty of lime, which will probably play a much more important part in the reconstruction than it did in construction before the war. Tile can be produced in quantity, and in the Ardennes there used to be thousands of little shops that produced hardware. As for wood, all the departments can furnish some, but how much will be available will not be known for some time. Roofing slates can be produced in large quantities in the Ardennes and the Meurthe-et-Moselle, also in the Nord and the Pas-de-Calais. Glass comes from the North, from the Aisne and from Belgium. The chief things needed, however, to provide each of these materials, are the necessary tools and machinery for extracting and preparing them for general use, and the technical service of reconstruction is trying to accumulate stocks of such supplies in advance.

In the spring of 1917 a million acres of land were released, of which at least 500,000 were tillable. During 1917 the tractor service of the Department of Agriculture plowed 80,000 acres, the French Army plowed 12,000 acres and the British Army plowed about 50,000 acres. At that time the Government owned 800 tractors and had on order 1500 more. It is probable that it has today over 1500 tractors, of which half are available for the devastated regions.

During the last German retreat the wheat was cut on 130,000 acres of released land. In this work, 16,993 men were employed, mostly military; 3324 horses, 9895 scythes and sickles and 823 binders.

During the summer and autumn of 1917 the Office of Agricultural Reconstitution, through the special mission of the agricultural coöperative societies, founded 120 agricultural coöperative associations in as many villages in the Somme, Aisne and the Pas-de-Calais. These coöperatives include in some cases in their membership nearly all the farmers in the commune. Among them they had nearly 100,000 acres of land under cultivation, and had a total membership of nearly 8000. Virtually all of them were wiped out by the German advance in the spring of 1918. The mission is trying to reorganize them and to create other coöperatives to stock them with implements, machines and cattle, so that they can start operation as units on their return to their native villages. The $20,000,000 credit which was recently voted for encouraging agriculture is being used in part for the founding of these coöperatives.

The Office of Agricultural Reconstitution is in charge of the work. It did all that it could to prepare for plowing and planting a section of released land last autumn. It would like to allow many thousands of the land proprietors to return, with their families where necessary, and to provide them with German prisoners or soldiers to help them. But, most unfortunately, it was almost impossible to provide for the plowing and cultivation of this land, aside from the fact that labor is extremely difficult to get, as there were very few horses and oxen available. Some 12,000 horses were taken every month for the American or French Armies, and even where the horses are available they cost today about $1000.



WRECKED FARMING IMPLEMENTS LIE HEAPED ABOUT RUINED COTTAGES

But what is worse, if the horses and cattle had been taken into the devastated regions it would have been almost impossible to feed them, for the Army needed all the oats that could be brought into the regions. To replace the horses the Government ordered a large number of tractors and several types of agricultural machinery, but deliveries are slow and not adequate to the demands. The Government has contracted for $8,000,000 worth of agricultural implements, but so far very few of them have been delivered. The Government is making advances up to $160 per acre, to help put back under cultivation land overrun by the Germans.

The result is, that while France needs all the crops that can be raised on the liberated farms, it seems to be impossible to get the crops started and taken care of, until the military situation permits. The immediate need is for large quantities of agricultural machinery and implements, and especially for horses and oats.

WRECKED BUILDINGS AT COAL MINES

About Dec. 1, 15,000 horses were released by the Army for agricultural work in the devastated region.

To meet the enormous need for industrial materials, machinery and tools, after the war, the Office of Industrial Reconstitution has been organized and has been composed half of officials and half of manufacturers. It has a credit of $50,000,000 to arrange for buying up raw materials, machinery, tools, etc., and it arranges for ceding them to the injured manufacturers. It is not equipped to buy and sell on a large scale itself, but has entrusted its credit to a private body organized for this purpose. This organization, formed in the first year of the war, is called *L'Association Centrale pour la Réprise de l'Activité Industrielle dans les Régions Envahies.* It is composed of most of the industrial people in the invaded departments. Its object is to employ every useful means for restoring the machinery and stocks destroyed. However, according to French law, the group cannot trade. It can only be a consulting and plan-forming body, therefore it created the *Comptoir Centrale d'Achats Industriels pour les Régions Envahies.*

The latter has a capital of $200,000. It has a council which controls all buying and selling and which authorizes the projects of each of the subcommittees for each kind of industry to buy and sell. Each project must also be approved by the Office of Reconstitution, which allocates the necessary funds from its credit. The *comptoir* can buy directly for a private owner, or it can constitute general stocks for later use. The recipient can pay for tools or machinery in cash, or he can have the total deducted from his eventual state indemnity. Cash is not given to the manufacturer. This is to save his money by wholesale quantity buying and to prevent the unfortunate effect on the market of a number of little buyers competing against one another.

At present these services have effected purchases to the amount of about $12,000,000 and prepared orders for machinery, tools, and raw materials for more than $40,000,000. These orders are especially assigned to the reconstitution of coal mines, of central electric power plants and of their distribution works, of general tools, etc. Other orders, to a total amount of $30,000,000, are now being prepared for textile industries, breweries, sugar mills, oil and grease plants. Supplementary credit on new orders is expected in a short while. The *comptoir* can, by its constitution, make no profits; merely its running expenses and 5% on its actually paid-in private capital.

Latterly, the association has been agitating for the organization of coöperative societies among manufacturers of the same kind of material. One such has already been formed among the steel manufacturers. As they cannot all be reëstablished at once, the first one or more to start operate against capital or advanced indemnity credit, furnished pro rata by all, and the profits are divided pro rata. Aside from allowing all to get some start almost immediately, it means a considerable saving to all by permitting extensive standardization of building plant, machinery, tools and stocks. The association is also keeping track of skilled labor in the respective industries, so as to have it ready when the plants are available.

The leading societies of architects in France have been working since the beginning of the war to make plans for reconstruction. They have a great deal to do with the recent organization in the French Government for handling the work in the invaded departments. They are now organizing coöperative societies among themselves for reconstruction. They have organized an exhibition of cheap housing, which took place in the garden of the Tuileries in the summer of 1916. In the autumn of 1917, together with the Ministry of Fine Arts, they organized a competition among architects, engineers, sanitarians and agricultural experts throughout France, for the production of better types of farm houses and town buildings of various sorts, with due reference to the regional architecture and customs.

The contractors of France, through their large associations, have worked with the Government in the creation of its present policy, and many smaller groups have been formed to prepare for reconstruction. The national associations have just formed a group of coöperative societies for handling reconstruction. The initial buying of materials and caring for labor will be aided by the Government.

The agricultural societies have also taken an active part in preparing for the reëstablishment of agriculture, and meanwhile they have been a great help in bringing immediate relief to the returning refugee farmers.

The sanitarian and public health groups have also taken an active part in preparing for the industrial reconstitution of the invaded departments, and in particular the new society called the *Association Nationale pour l'Expansion Économique* has made full studies of the industrial, commercial and agricultural needs, and has made extensive preparations for after the war.

From the standpoint of town planning, the society created since the war called *La Renaissance des Citiés* has already made full studies for the improvement of the plans of Arras, Albert and other towns. It is now collaborating with the mayor and the council of Chauny to hold a big competition for plans for the improvement of the layout of the town.

From the legal side, *La Fédération Nationale des Associations Départmentales des Ministrés*, the judicial committee of *La Renaissance des Citiés*, the judicial committee of the *Union Centrale des Comités-des Réfugies and the Comité d'Action pour la Reparation Integrale des Dommages de Guerre* have all made extensive studies of laws affecting refugees, war indemnities, redistribution of farm land, sanitation, etc. They are all having a strong influence on the legislation now before the French Parliament.

Reconstitution Work Done by Private Groups

A great many societies and individuals have been doing important relief work in the invaded departments. Their work is now coördinated in a special bureau of the Ministry of the Liberated Regions. They have been giving or selling clothing, furniture, cooking utensils, farming implements, seeds, fertilizers, farm animals, bedding and food to the returning refugees. The American Red Cross has had a delegate in each of the invaded departments, with several assistants in each department. They worked directly with the French authorities, and have distributed large amounts of urgency supplies in these regions.

The Anglo-American Friends' Mission has been working in the devastated regions ever since the beginning of the war. Its first work was in the Meuse and the Marne in the district between Vitry-le-François and Bar-le-Duc. In the spring and summer of 1917 they did splendid work in the Aisne and the Somme. They have several workers, men and women, in the field distributing relief of all kinds. Now they are planning a big reconstruction effort southwest of Verdun.

The Smith College Unit did similar relief work in about 25 communes around Grécourt in the Somme, until driven out last spring. Some 30 or 40 other French, British or American groups have been doing general or local relief work in the devastated regions. The Minister of Liberated Regions is now distributing among these and other groups the relief work to be done soon.

As regards repair work, the American Red Cross during 1917 repaired with its own labor about 75 buildings in five villages in the Somme, northeast of Nesle and northwest of Ham, and south of Péronne. The Anglo-American Friends mounted 51 demountable barracks in six villages near Ham and at Gruny, near Roye, in the Somme and repaired about 30 or 40 buildings in the Marne and the Meuse; during the first three years of the war they repaired several hundred buildings, especially in the towns of Sernaize, Pagny, Heiltz-le-Maurupt. They are now back at work in the Aisne and the Meuse.

The Californian Mission of Mrs. Crocker and Miss Daisy Polk adopted the village of Vitrimont in the Meurthe-et-Moselle and have repaired almost all of the 50 properties in the town. Various French cities and towns have adopted destroyed towns and villages. For example, St. Mihiel has recently been adopted by Nantes, Lyons has adopted St. Quentin and other towns in the devastated regions, and there are many other more or less official cases of such adoption.

The Reconstitution Research service of the American Red Cross has been working directly with the French Government and with most of the leading French associations and societies, to help them to establish a program of after-war reconstitution work, especially to aid the small farmer and workingman. The policy has been to bring together the leading French specialists and authorities to consider the problems of common interest with regard to after-war reëstablishment, and to secure an agreement on standards of practical improvements to be adopted in the planning, construction, furnishing and equipping of houses, farms and town buildings, with a special view to sanitation, economy and operation. The intent is, that once these standards are determined they shall be given general publicity among the returning refugees, with a view to getting them adopted in the reconstruction of the buildings and the reëstablishment of the livelihood of the people. A number of tracts have been published and a number of typical improved plans, with specifications and data, have been prepared. An extensive library and documentation on all phases of reconstruction have been collected, and the most useful material has been briefed. Everything is ready to start a big campaign of propaganda, with special emphasis on improving sanitation and hygiene.

Control of Main Routes by State Commissions

That the control of a state-wide system of roads should be vested in the State Highway Commission is the opinion expressed in the latest annual report of the Alabama commission. The present law gives the initiative in all construction work to the counties, but the report states that while this generally works to the benefit of the county, it frequently is not to the best advantage of the state. A trunk-road system of about 3000 miles was designated by the last legislature, of which about 1500 miles are constructed and in good condition. However, many short gaps in important trunk lines occur at the borders of counties, as the county officials neglect these portions and will not apply for state or Federal aid for their improvement. It is held, therefore, that the State Highway Commission should have authority to improve these neglected sections, in order to make the trunk roads continuous as intended.

Pay and Position of Engineers in Railway Service

Comparison with Wages Paid to Solicitors, Machinists and Trainmen Shows Low Relative Compensation For Technical Men

By Charles Whiting Baker
Consulting Editor "Engineering News-Record"

At this time, when public attention is concentrated as never before on the railway transportation lines of the country, it is surely opportune to call attention to the position which is held by professional engineers in the railway service. Rather let us say the *lack* of position; for the unfortunate fact is that the average engineer who works for a railway company receives lower pay than the mechanics working in the repair shops and very much lower pay than the employees in train service.

Many of the men engaged in railway engineering have spent four years or more in acquiring a technical education, have long experience in practical work, and are performing responsible tasks, where the application of their technical knowledge and ability has an important influence on the economical use of both material and labor; yet the average compensation of these engineers is about the same as that of the hostler who cleans a locomotive in the roundhouse, or of the man who handles trunks in the baggage car. As for the aristocrat of the railway service—the man who handles the throttle of a passenger locomotive and whose right to the title "engineer" has often been protested by the men who hold engineering to be a profession—he draws monthly from the pay car nearly twice as much money as the average assistant engineer or draftsman receives.

The inadequate compensation of railway professional engineers is not merely a flagrant injustice to men who give to the railway service the results of long years of technical study and experience; it is the most wasteful sort of economy thus to misuse the men whose ability the railways greatly need in order to solve the difficult problem of increasing the economy and efficiency of railway operation.

Inadequate Compensation of Long Standing

The inadequate compensation and lack of position of engineers in the railway service is a matter of long standing. It has come to the fore recently, since Government control of railways was established, because the organization of the Railroad Wage Commission by the Director General gave opportunity for the engineering employees to present their pleas for higher pay.

Furthermore, the engineer, like every other man, has had to face a rapidly mounting increase in the cost of living for himself and his family during the four years of the war. While his salary was meager enough for his living expenses in 1914, he received practically no increase of any consequence since then until the general advance in all railway wages was put into effect by the Railroad Administration last year.

It has long been known in a general way that railway engineering service was inadequately paid. The professors in leading engineering schools, in advising their young graduates where to look for positions, have in many cases warned them of the small pay and slow promotion which they could expect in the railway service. There are probably few, however, in the profession—outside of those directly in railway service—who realize what the engineer who works for a railway company has had to contend with.

It seems worth while, therefore, to present in considerable detail the facts and figures as to the pay of railway engineers, compared with that of other classes of employees. These have been obtained from the official statistical reports of the Interstate Commerce Commission and the report of the Railroad Wage Commission, supplemented by the recent official orders increasing wage rates. The last published statistical report of the Interstate Commerce Commission was for the year which ended June 30, 1916. The report of the Railway Wage Commission continues the figures down to 1917.

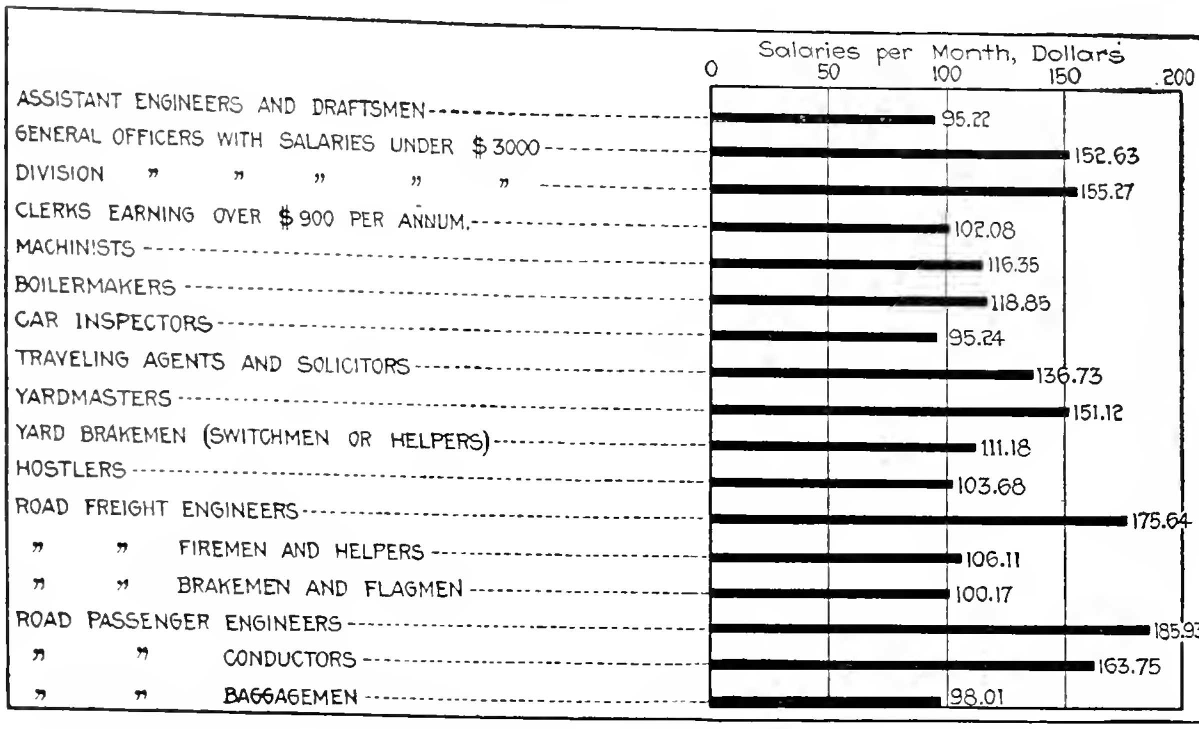
Salaries of Railway Officers

The Interstate Commerce Commission classes all those engaged in railway engineering service under the title "Assistant Engineers and Draftsmen," with the exception of engineers who hold such positions of authority that they are included under the heading of "general" or "division" officers.

Of course, a considerable number of the engineers engaged in railway work are classed as "officers," and it may be well just here, therefore, to drive a nail into the current fallacy that the average railway officer is in receipt of a princely income. The fact is, that while a very few of the highest railway officers, such as the president and the vice-presidents on a large system, receive liberal salaries (especially when they are in close relation with the financial interests which control the company) the rank and file of the officers on whom the responsibility for operation chiefly falls receive salaries which are on the average much below those paid by manufacturing or commercial bodies for the assumption of similar heavy responsibilities.

The Interstate Commerce Commission's figures for the year which ended June 30, 1916, make the following showing for the officers of Class I companies (those having gross earnings exceeding $1,000,000 per annum): The total number of general officers drawing salaries above $3000 per annum was 3958, an average of two per 100 miles of line. The average daily pay of these general officers was $20.75. Their total salaries amounted to only $26,217,000, which was less than 2% of the total payroll of these railway companies. Of the general officers with salaries under $3000 per annum, the total number was 3312. Their average salary was $5.60 per day. Of the division officers there were 1098 who drew salaries above $3000 per annum, and 8878 whose salaries were less than that amount. The average daily pay of these higher division officials was $7.10 and of the lowest paid men $5.01.

When it is borne in mind that these figures include the officials of all departments of the railway service it will be obvious that the engineers constitute no very large percentage of the number. These figures make it evident also that the men who are holding these official positions are not in receipt of what can be called high salaries. If the salaries of the few very highly paid officials, such as the president, had been deducted from the above figures before the averages were made up, it would be even more obvious that the rank and file of the railway officers were receiving nothing extravagant in the way of salaries in 1915. The figures presented in the table which accompanies this article show that, like many other salaried men, they have had to face the rapidly mounting cost of living during the war with practically stationary incomes.



COMPARISON OF SALARIES PAID TO RAILWAY PROFESSIONAL ENGINEERS AND OTHERS

Assistant Engineers and Draftsmen

Let us turn now to the rank and file of engineers in railway service who are not listed as officers. They are all grouped together, whether employed in the chief engineer's department, the motive-power department, or in any other branch of railway work, as "assistant engineers and draftsmen." There were 8879 such men employed by Class I railway companies in 1916, *and their average monthly pay was $93.76*. The Interstate Commerce Commission figures state the average compensation per day of these men as $3.45.

It has been said that the best way for a man to cultivate optimism is to regard the lot of someone who is worse off than he is. It is well to set down, therefore, for the benefit of assistant engineers who are lucky enough to have jobs with the Class I railway companies, that their fellow members of the profession who had jobs with the Class II railway companies (those having earnings between $100,000 and $1,000,000 per annum) made average daily earnings in 1916 of only $2.88.

The draftsmen and assistant engineers who worked for the little branch railways, included in Class III (earning less than $100,000 per annum) earned on the average $2.817 per day. No doubt the seven-tenths of a cent looked good to these men. Fortunately for the profession, these Class III railway companies get along with only 41 assistant engineers and draftsmen, though their total extent is 8762 miles. It is evident, therefore, that the financial slough in which these small branch railway companies, almost without exception, wallow is not due to extravagance in payment for engineering service!

Turning back to the assistant engineers and draftsmen working for the Class I railway companies, it is worth noting that their pay varies considerably in different parts of the country. Those working in the Eastern district, which includes the principal trunk lines, were paid in 1916 an average of $3.58 per day. Engineers in the South have to get along with $3.38, and on the railways west of Chicago the compensation is $3.33 per day.

Now let us see how the pay of these assistant engineers and draftsmen in railway service compares with the pay received by other classes of railway employees. In the accompanying table a comparison is made for certain selected classes of employees, including a number of those which have earnings approximating or exceeding those of the engineers. The first two columns of this table give the total number of employees in each class in 1916 and the total wages paid to them as given in the statistical report of the Interstate Commerce Commission for that year. The next three columns, showing the average monthly earnings in 1915, 1916 and 1917, are taken directly from the report of the Railroad Wage Commission to the Director General of Railroads. The last column contains figures computed from the general order increasing wages issued by the Director General last May, modified by various supplementary orders, under which railway employees of all classes have received in 1918, it is stated, $636,000,000 more than they did in the year previous.

Only an Approximation Possible

It should be said for this last column that it is necessarily only an approximation. The allowances for overtime, minimum wage rate, etc., for the mechanics working on the hourly basis and for the train employees paid on the mileage basis make an accurate statement of actual average yearly earnings impossible until the statistics of the Interstate Commerce Commission for 1918 are finally made up. The figures in this last column are accurate enough, however, to give a fair idea of where the professional engineer finds himself at the present day in comparison with the mechanics in the shops, the employees in the train service, and other railway men.

There is no intention here to discuss at length the increases which have been made in railway wages, or to criticize the action of the Federal railway managers. They had to cope with conditions which compelled large

increases to the mechanics in the shops and to the train-service employees. The men in the repair shops were absolutely essential to the railway organization under the conditions existing a year ago. Something had to be done to offset the temptingly high wages in the munition plants and to recognize the situation of these men on account of the mounting cost of living. The rights of the train-service employees under the Congressional enactment of 1916 establishing the eight-hour day had to be recognized; and the Brotherhood officers were not negligent in insisting on these rights.

It is well to set down here just what the basis of pay is, for these classes of employees. The wages of machinists, boiler makers and other skilled mechanics employed in railway shops were raised last year by "Supplement 4 to General Order 27," in the following manner: A basic minimum rate of 55c. per hour was established, and to this rate and any higher rates which were in effect Jan. 1, 1918, there was added 13c. per hour, making the minimum base rate 68c. per hour. For any work in excess of eight hours, time and a half is allowed. At this rate, with no overtime earnings, a machinist would receive $5.44 per day or $141.44 per month of 26 days.

Most of the employees in railway train service are paid on a mileage basis, and an elaborate table was published in General Order 27 showing the amount of increase in proportion to past wages for each class of train-service employees. It is impossible to apply these increases to the past average earnings of men in train service, shown in the table herewith, so as to determine just what average pay these men are now drawing.

It has been assumed, therefore, that the general percentage of increases in mileage rates which was established by Order 27 will represent a fair average for all classes of train-service employees. These percentages of increase were as follows:

	Per cent
Road freight engineers	15½
Road freight firemen and helpers	34¼
Road freight brakemen	39½
Road passengers engineers	11¼
Road conductors	15½
Road baggagemen	38¼

These figures, however, obviously do not tell all the story, for under the Adamson law as enacted in September, 1916, all the train-service employees now receive time and a half for all work over eight hours.

How much the eight-hour day is increasing the average earnings of railway employees in addition to the increases in wage rates established by the Railroad Administration will not be known until the Interstate Commerce statistics are available, nearly two years hence.

Those who know what is going on in the railway service, however, believe that a very considerable amount of railway revenue is now being paid out for overtime which is only made necessary by the employees themselves. In fact the time-and-a-half pay for overtime establishes a premium on petty graft in the railway service—petty, that is, as far as the individual is concerned, but anything but petty in its effect on railway revenues.

It need not be assumed that the train-service employees are satisfied with the increases which they received last year. Late reports from Washington state that they are seeking additional increases from the Railway Wage Board which will raise their total pay by something like $100,000,000 per annum, and a possible further increase in freight rates is said to be under consideration to meet this new demand.

It may be said that all this is not pertinent to the question here discussed as to whether the professional engineers in railway service are adequately paid for their work. But the standing excuse for the meager pay to engineers has long been that the railways were too poor to pay any more. It is therefore, pertinent to show that if the railways can let their revenues be dissipated for over-time pay for work that could often be obviated they can surely afford to pay a living salary to their professional engineers.

Let it be here set down also that the professional engineer in many cases gets neither time-and-a-half nor any extra pay whatever when he works overtime, as he is often obliged to do. In the days when railway surveys were a big factor in American engineering work, the engineer was accustomed to work from daylight to dark in the field, and to amuse himself in the evenings by writing up notebooks, drawing maps and in similar pleasant recreation. Somewhat of that tradition still survives among railway engineers. They are supposed to be on the job whenever the exigencies of the service demand, all at so much per, and their esprit de corps dignity would suffer, it is assumed, by the payment of extra compensation for over-time work!*

In the orders which have been issued granting increases of pay to various classes of railway employees the engineer *has never attained the dignity of a separate classification.* According to our information, all the men in railway service classed as "assistant engineers and draftsmen" by the Interstate Commerce Commission are included under "Supplement 7 to General Order 27." We quote as follows from this order: "For all employees who devote a majority of their time to clerical work of any description, including train announcers, gatemen, checkers, baggage and parcel-room employees, train and engine callers, and the operators of all office or station equipment devices, establish a basic minimum rate of $62.50 per month. To this basic minimum rate and all rates above, in effect Jan. 1, 1918, add $25 per month."

Thus, the professional engineer with technical education and experience finds himself classed with clerks, train announcers and the men who check baggage, as far as pay is concerned, and, it is a fair corollary, as far as position also is concerned!

What does all this mean to the professional engineers who are striving to do their work under such conditions? It means that for the past four years they have had to support themselves and their families on an average salary smaller than the wages of a chauffeur; that they have had to do this while year by year the cost of food and clothing and other necessaries of life

*Recent orders of the Federal Railway Administration have made some allowance for overtime work by engineers. For example, in a certain railroad office in New York City the assistant engineers and draftsmen have the same hours as most office workers there, from 9 a.m. to 5 p.m. with an hour for luncheon. This is a 7-hour day. If the work demands an extra hour time, no extra pay is given for it. For the 9th and 10th hour extra pay at single time rates is given and after ten hours, time and a half. Where work is required on Sundays or holidays, extra pay is given at the rate of single time for 8 hours and after that the same as above. This is much more favorable treatment as respects extra pay for overtime work than has before been granted to engineers.

has gone on mounting. When an increase was finally granted this year it averaged only 27%, while the cost of the necessaries of life, according to the statistics of the Railway Wage Commission itself, has increased over 40% and general experience places the increase in the cost of living during the past five years at fully 70 to 100 per cent.

To expect a man to do good work under such conditions is to expect the impossible. The inevitable result is to tend to drive engineers out of the railway service into some other occupation where they can earn a decent living for themselves and their families.

Let us not comfort ourselves with the idea, either, that some of the engineers in railway service who hold responsible positions are earning salaries considerably larger than the averages here shown. We cannot get away from the fact that if a considerable number of railway engineers are drawing better salaries than are indicated by the figures above, then another lot of poor fellows are getting even less than the starvation pay which the above averages represent.

This situation above set forth, however, is of much more serious import to the public than are the hardships suffered by the ten thousand or so engineers and draftsmen in railway service. *The railway business is today suffering from its failure to give the engineer proper position and responsibility and compensation.* These engineers are using their brains, not their muscles, in the railway service. Upon their ability and initiative depend to a very large extent *the economy and efficiency with which the materials and the labor which the railway company buys will be utilized.*

As one studies the accompanying table of wage rates and the diagram, one must seriously ask the question: Where is the incentive for the railway engineer to use his best efforts to save money for the company? Does anyone thank him if he exerts himself to find a way to save material here, or to dispense with an extra man there? Director General McAdoo has called public attention to the serious breakdown of morale in the railway service. How could anything else be expected? Engineers are supposed to be in a position of authority over construction and other work. Their authority and their ability to look after the railway company's interests are neutralized by inadequate pay and position.

Contractors' employees doing work under direction of railway engineers are in many cases earning twice as much as the engineer who gives them orders. A recent letter describes the experience of an engineer of long experience in charge of construction work who had occasion to give an order to the brakeman of a train. The answer was prompt, "Who the hell are you to tell me what to do? My pay check is bigger than yours!"

How long would discipline and efficiency last in an army if the captains and colonels were paid less than the noncommissioned officers?

It is pretty well known in railway circles that the reason for the enormous increase in railway operating expenses is not merely the increase in the rate of wages but the falling off in the efficiency and industry of the employees. How is this to be remedied if the men who should be in authority are so treated as to destroy their initiative and their interest in their work?

AVERAGE MONTHLY EARNINGS OF CERTAIN CLASSES OF RAILWAY OFFICERS AND EMPLOYEES OF CLASS I RAILWAY COMPANIES (THOSE HAVING GROSS EARNINGS IN EXCESS OF $1,000,000 PER ANNUM) FOR SUCCESSIVE YEARS

			Average Monthly Earnings for the Year Ending			
Occupation	Total No. Employed in 1916	Total Wages in 1916	June 30, 1915	Dec. 31, 1916	Dec. 31, 1917	Dec. 31, 1918
Assistant engineers and draftsmen	8,879	$9,925,050	$93.42	$93.76	$95.22	$120.22
General officers with salaries below $3000	3,312	5,909,462	151.88	151.91	152.63	175.95
Division officers with salaries below $3000	8,878	15,228,380	147.62	147.64	155.27	172.55
Clerks earning $900 and upward	61,667	70,788,932	94.05	99.16	102.08	127.08
Machinists	36,602	40,837,054	85.87	100.42	116.35	See note
Boilermakers	11,944	13,772,489	89.88	102.46	118.85	See note
Car inspectors	17,904	16,281,753	73.48	81.11	95.24	See note
Traveling agents and solicitors	5,925	8,858,663	123.83	130.54	136.73	158.10
Yardmasters	3,415	5,463,154	131.09	135.35	151.12	162.35
Yard brakemen (switchmen or helpers)	37,476	44,370,600	91.93	99.81	111.18	See note
Hostlers	7,031	7,229,807	80.95	87.93	103.68	See note
Road freight engineers	29,645	55,030,111	152.75	154.32	175.64	178.24*
Road freight firemen and helpers	31,499	55,511,425	94.10	93.82	106.11	125.72*
Road freight brakemen and flagmen	60,019	62,636,087	85.83	87.70	100.17	110.78*
Road freight passenger engineers	13,318	28,014,930	178.46	177.04	185.93	196.51*
Road passenger conductors	10,676	19,682,805	153.57	156.41	163.75	175.60*
Road passenger baggagemen	5,617	6,005,841	87.03	91.49	98.01	126.35*

NOTE—The establishment of minimum rates of wages with the eight-hour day and time and a half for overtime makes it impossible to state present average pay of employees paid by the hour. The increase, however, is undoubtedly much larger proportionally than the increase received by the engineers.

* Most of these men in train service are paid on a mileage basis and with the eight-hour day in force probably receive on the average considerably higher rates than those here given.

In this connection let emphasis be given to Director General McAdoo's recent declaration that "upon the efficiency of the country's transportation system the future prospect of the nation largely depends." Where is one to look in the railway service for the men of technical education and experience who have made a thorough study of the larger problems of transportation economies such as will fit them for leadership as railway officers? Where save in the ranks of engineers?

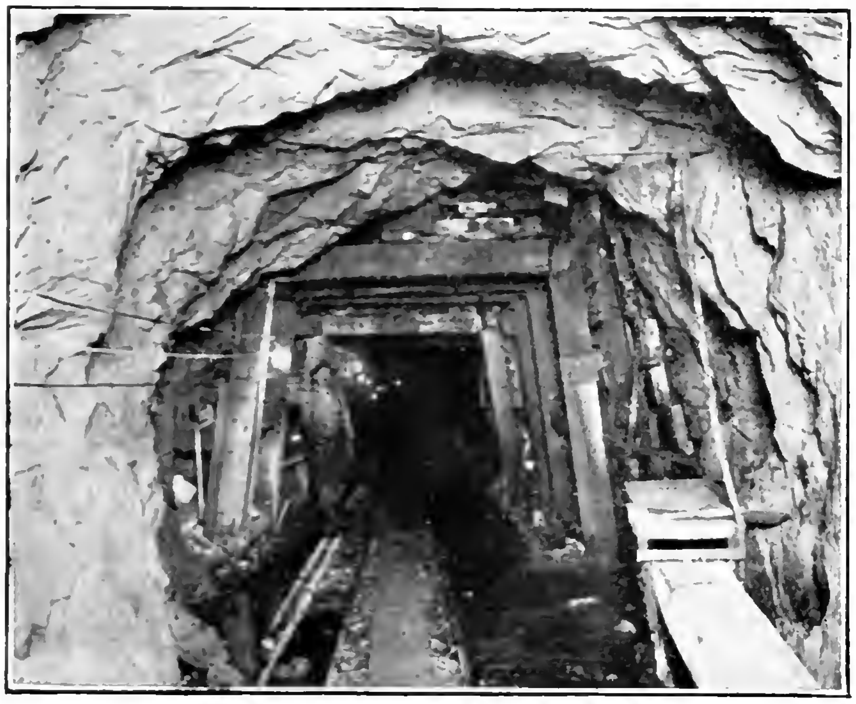
It is of the greatest importance to the country's welfare that young men of character and ability should be attracted to the railway service, and that their treatment and opportunities there should be such as to retain them. Obviously, the very reverse of such conditions exist today. The showing of the accompanying table and diagram will of itself be sufficient to make the bright young graduate engineer hunt anywhere else than in the railway service for a position.

What can the engineering profession do to remedy the conditions here depicted? The Engineering Council has appealed to the Board on Railroad Wages and Working Conditions, and is continuing its efforts; but the fact that the council is at work should stimulate rather than retard action by individual engineers and by organizations. Protests to that board (whose offices are at 1300 Pennsylvania Ave., Washington, D. C.) should emphasize not merely the inadequate pay of the professional engineers in railway service, but the unwisdom of classing them with clerks and low-grade workmen, when their authority and initiative are so important to the railway service.

The engineer is not asking better pay and position merely because he earns it and deserves it, as he undoubtedly does. It is because of the service that engineers can render in increasing economy, and efficiency in railway operations that the value of that service should be adequately recognized.

Fluming a Stream to Unwater a Tunnel

When the South Fork heading of the 18-mile tunnel on the Hetch Hetchy aqueduct had advanced about 300 ft., a heavy flow of water filled the 11-ft. width of the tunnel to a depth of about 4 ft. An examination showed that this water came entirely from the adjacent stream bed, through a geological fault line. Along this fault the rock had separated



FLUMING A STREAM STOPPED THE TUNNEL LEAK

about 6 ft., the fissure being filled with decomposed rock and gravel. The fault extends to the surface of the ground above and can be easily traced on both sides of the cañon.

Soon after the heading struck the fault the stream flow decreased by about as much as the flow in the tunnel, and plans were immediately made for diverting the stream into a flume above the fault line. The fall of the stream was such that 30 ft. of flume sufficed to bypass the water around the fault line. In the meantime timbers had been floated into the tunnel and work was continued; first the loose section, about 30 ft. long, where the tunnel crossed the fault line, was shored up.

After the stream was turned into the diversion flume, the flow in the tunnel decreased to an amount that could be conveniently handled by a 16-in. pipe. Some of this water is considered to be drainage from the fissure, and the remainder is ascribed to underflow beneath the stream bed. Beyond the fault line no water whatever was encountered. The heading was in about 700 ft. when visited by a representative of this journal in August. This work is being carried out by the City of San Francisco under the direction of M. M. O'Shaughnessy, city engineer.

Chlorination Interruptions Costly

Failure to operate water-supply chlorination plants continuously and effectively in several municipalities in New York has resulted disastrously for the inhabitants. Serious outbreaks of typhoid have been experienced, and, in one instance, the State Department of Health reports, 100 cases occurred in a town of 10,000 population three weeks (the usual incubation period) after the sterilization apparatus, through neglect, had failed to operate for five days.

Tests Show Value of Fine Grinding of Portland Cement

Fine-ground cement, specified to pass 90% through a 200-mesh sieve, is being used in the Government concrete ships. The tests on which this use was based are reported as follows in the annual report of the Bureau of Standards for the fiscal year which ended June 30, 1918:

"The series of tests, started in 1916, to determine the effect of increased fineness on the cementing value of cement in mortar and concrete has been continued. The two-year results show the same marked decrease in strength with the finer ground cements as did the tests of the previous year.

"With knowledge of the general results of this investigation the Emergency Fleet Corporation requested further comparative tests on various cements produced in the Southern districts, both as normally ground and as reground to a fineness of 90% passing the 200-mesh sieve. These cements were tested in 1: 1: 2, 1: 1½: 3, and 1: 2: 4 concretes and in 1: 2 mortar. In practically all cases the increase in compressive strength obtained with the finer cements was from 50 to 100 lb. per square inch for each per cent. increase in fineness. From all the data obtained in this investigation the order of increase in strength which may be expected from finer grinding by ordinary methods is now fairly well established, and the question of requiring higher fineness in the standard specification for portland cement is a purely economic one. There remains, however, the highly interesting and almost wholly unattacked problem of producing cements of much higher fineness than is possible by ordinary methods of grinding. It may confidently be expected that if practical methods can be found of reducing cement clinker to a very fine state of subdivision, a decided improvement in quality will result. To determine what degree of improvement may be obtained is properly the next step in this investigation.

"The importance of further progress along these lines is commensurate with the difficulties to be overcome in developing new methods of grinding, and concentrated effort will be required to deal with the new problem effectively. Fortunately, some progress was made before the war by the development of an air separator and an air analyzer for the production and mechanical analysis of very fine cements."

Bonus Payments Speed Up Shaft Sinking

Well-organized shifts and bonus payments were largely responsible for the unusual speed of nearly 200 ft. a month for five months in sinking a 11 x 21-ft. rock shaft for the Seneca Mining Co., at Mohawk, Mich. A flat rate per day was paid up to the first 100 ft. per month; 2c. per foot per day bonus was paid for all over 100 ft. up to 150 ft.; 3c. per foot per day for all over 150 up to 200 ft. and 4c. per foot per day for all over 200 ft. per month. A total of 994 ft. of shaft was sunk in 129 working days in five months from May to September, or an average of 7.7 ft. per day. The highest monthly rate was 208 ft. in 27 days in May, and the lowest was 184 ft. in 24 days in September.

Experimental Data on Wood-Blocks—Use of Zinc-Treated Ties

Extracts from two of the papers presented at the fifteenth annual meeting of the American Wood Preservers' Association at St. Louis, Jan. 28-29, giving (1) the results of investigations on experimental wood-block pavement in Minneapolis, and (2) the influence of rainfall upon the durability of zinc-treated cross-ties.—EDITOR.

Progress Reported on Wood-Block Experiments in Minneapolis

BY C. H. TEESDALE AND J. D. MACLEAN
Engineers in Forest Products, Forest Products Laboratory, Madison, Wis.

THE object of this report is to discuss the results of investigations made on an experimental wood-block pavement, after 12 years' service under heavy traffic conditions. This pavement was laid in coöperation with the City of Minneapolis for the purpose of studying the relative merits of various species of wood for paving material, and to investigate the influence of the following variables: (a) Heartwood and sapwood; (b) length of blocks, and (c) angle of courses.

Seven species of wood were employed: Tamarack, Norway pine, long-leaf pine, white birch, douglas fir, Western larch, and hemlock. On account of the wide use of long-leaf pine as a paving material, this species was used in the test to provide a basis of comparison for the other woods. A detailed discussion of the material used, the method of treating the blocks, and the construction of the pavement, is given in Forest Service Circulars 141 and 194, the latter issued Jan. 16, 1918.

One of the difficulties encountered in an experiment of this nature is in the selection of a method for judging the conditions from year to year. In order to determine a basis of comparison, the following method was adopted: (1) Measurement of the blocks to determine the average wear; (2) estimation of the total number of square feet in a section below the general level of the street; (3) estimation of the total number of square feet ½ in. or more below the general level of the pavement.

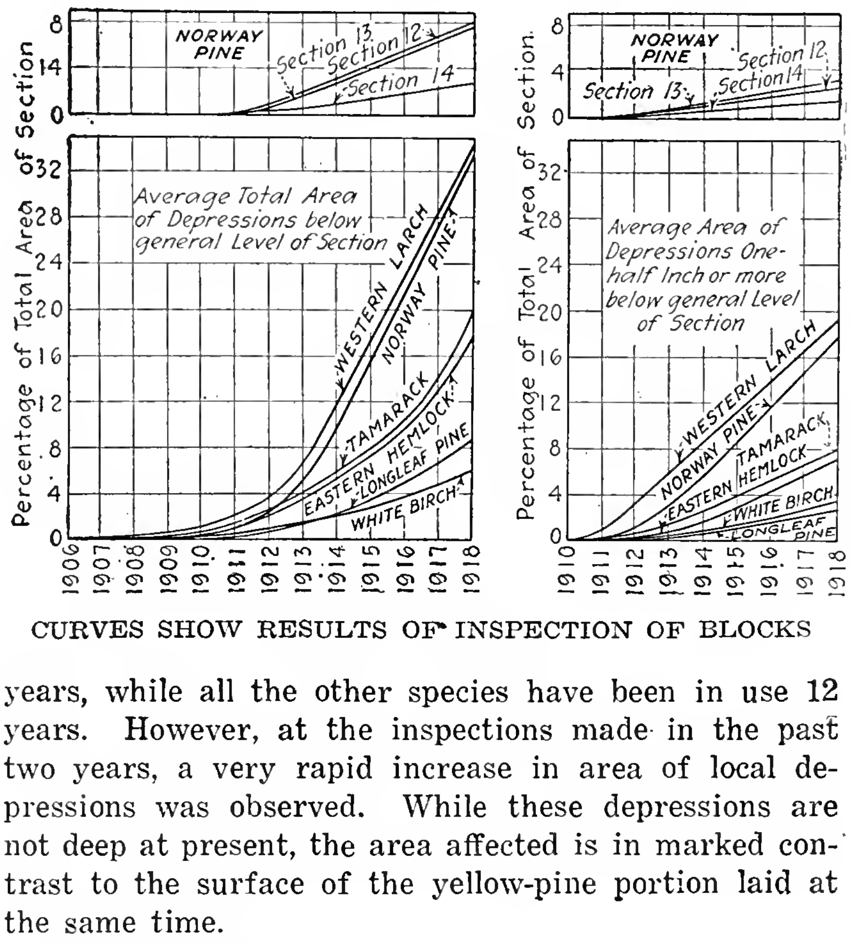
The wear of the various species was measured on a block removed from each section from a position about midway between the curb and the center of the street. It was selected from a portion of the pavement where the surface was fairly uniform. Measurements to the nearest $\frac{1}{16}$ in. were made at a number of points, and the average depth was determined. The difference between this and the original depth of the blocks was taken as the average wear of the section.

HOW ESTIMATES OF DEPRESSION WERE MADE

Estimates of the total number of square feet of depression below the general level of the surface, and ½ in. or more below the general level, were made independently by each member of the inspection party. These estimates were averaged and recorded. The data were plotted for each of the inspections and curves drawn showing the average results, as indicated in the diagrams in the next column.

In the early part of the summer of 1911 the douglas fir blocks were in such bad condition that it was necessary to relay the two sections composed of this species. Deep depressions had developed, and some of the blocks were badly broken. The failure of this wood after five years' service was probably due to the poor quality of the original blocks. To test this species further a quantity of Grade A material was obtained. There was not a sufficient amount of this douglas fir to replace entirely the sections removed, so the remaining area was paved with the regular yellow-pine blocks supplied by the city.

A good comparison of the durability of douglas fir with respect to the other species cannot be made at present, as the relaid material has been in use only seven



CURVES SHOW RESULTS OF INSPECTION OF BLOCKS

years, while all the other species have been in use 12 years. However, at the inspections made in the past two years, a very rapid increase in area of local depressions was observed. While these depressions are not deep at present, the area affected is in marked contrast to the surface of the yellow-pine portion laid at the same time.

Blocks of douglas fir which were removed for inspection showed an average wear and brooming from $\frac{5}{16}$ to ½ in., as compared with $\frac{3}{16}$ to ¼ in. for the yellow pine placed at the same time.

It will be noted from an inspection of the curves that it is impossible to predict the deterioration of a particular species from conditions observed during seven or eight years' service. Practically all of the species showed very small areas of depression for the first five or six years. After this period, however, the depressions suddenly increased in area at a very rapid rate. Results of the more recent inspections seem to indicate that the increase in depressions will be much more rapid in the future, and will necessitate the early replacement of some species.

There is no question that specimens of long-leaf pine and white birch are in a much better condition than

most of the others. The depressions in the white birch are somewhat more numerous and deeper than those in the long-leaf pine, but these depressions are largely due to the crushing down of blocks which were partly decayed before they were treated. Depressions in the long-leaf pine seemed to be due in a large degree to decay in the sapwood of individual blocks. Poor penetration, on account of moisture in the wood at the time of treatment, probably accounts for most of the cases of decay found in the sapwood.

Apparently, the white birch and the long-leaf pine may be classified on the basis of this experiment as about equally durable for paving purposes. An objectionable feature of white birch seems to be the difficulty in selecting material free from decay. The Norway pine section has large areas of depression and a considerable number of deep pockets. The bad condition of this section, however, is not a good criterion of the wearing qualities of the species. This section is triangular in shape, and therefore has but a small area which is not subjected to continually severe traffic conditions.

The Eastern hemlock seems to be in slightly better condition than the tamarack. However, there is not a very pronounced difference in the condition of these two species. The Western larch sections are in very poor condition. Compared with the other species, this wood has the largest percentage of area affected by depressions.

Measurements of wear were taken on all of the species until 1915. At this time the depressions had reached a state where it was not practicable to select blocks representing average conditions. In subsequent inspections a general estimate of the relative wear has been made. Beginning with the species showing the least wear at the last inspection, the approximate average wear and brooming is as follows: White birch, $\frac{3}{16}$ to $\frac{1}{4}$ in.; long-leaf pine, $\frac{5}{16}$ to $\frac{7}{16}$ in.; Norway pine, $\frac{1}{2}$ to $\frac{9}{16}$ in.; tamarack, $\frac{7}{16}$ to $\frac{5}{8}$ in., Eastern hemlock and Western larch, $\frac{5}{8}$ to $\frac{3}{4}$ inch.

Most of the wear on long-leaf pine and white birch blocks seemed to have taken place during the first five or six years of service. This was probably due largely to brooming of the fibers. Some of the other species, in which the wear was most pronounced, showed a general increase in wear from year to year.

Summary

1. The order of efficiency of service is as follows: (a) Long-leaf pine; (b) white birch; (c) Eastern hemlock; (d) tamarack; (e) Norway pine; (f) Western larch.

2. Since the relaid douglas fir has only been in service seven years, a good comparison of this wood cannot be made with the woods which have been in use for 12 years. At present the depressions and wear of this species are from two to three times as much as that of the long-leaf pine portion laid at the same time.

3. For most of the species the depressions were very slight during the first four or five years' service. After this period the depressions increased at a very rapid rate.

4. Certain sections show wearing qualities of Norway pine which compare favorably with those of long-leaf pine and white birch. These sections probably give a better comparison of the durability of this species than does the section which is subjected to unusually severe traffic conditions on account of its shape and location.

5. The Western larch sections have the greatest percentage of area affected by depression. This is also one of the species which shows the heaviest wear.

6. The order of the species, beginning with that showing the least wear, is as follows: White birch, long-leaf pine, Norway pine, tamarack, Eastern hemlock, and Western larch.

7. The presence of sapwood did not seem to be an important factor affecting the durability of the pavement.

8. The various lengths of blocks employed had no apparent influence on the wearing qualities of the pavement.

9. Less joint wear was noted in sections laid at 45° and 67½° than in the section of blocks laid at an angle of 90° with the curb.

Rainfall Influence on Durability of Zinc-Treated Cross-Ties

By C. H. Teesdale and S. W. Allen
Engineer in Forest Products — Industrial Examiner in Forest Products
Forest Products Laboratory, Madison, Wis.

The scarcity of creosote needed in timber treating for the past two years, due to the restrictions on imports and the increased use of coal tar for fuel by the steel industry, has directed attention to the possible wider use of other treating materials, especially for cross-ties. Among those under consideration zinc chloride has been most commonly used, and a large number of service records on zinc-treated cross-ties were available.

Accordingly, it was proposed to plot these records on a map of the United States to determine if possible the relation between the location of successful tests of zinc-treated ties for different periods of service, on the one hand, and lines of equal rainfall, on the other. By this means it was hoped to suggest a more or less definite area where zinc chloride could be used to the exclusion of creosote.

The *Proceedings* of the American Railway Engineering Association and of the American Wood Preservers' Association were consulted for data on service tests of zinc-treated ties, and where exact locations were not shown they were determined by consulting original records from various roads, on file at the Forest Products Laboratory. The location of lines of equal rainfall were taken from Bulletin Q of the Weather Bureau, United States Department of Agriculture.

Three outline maps of the United States were prepared, showing the geographical location of test tracks containing zinc-treated cross-ties which had been in service for eight years, for 10 years and for 12 years. Those tracks where 25% or less of all zinc-treated ties had been removed in this period, and those where 50 to 100% had been removed, were designated by different symbols.

Comparatively few records are available south and east of the 40-in. rainfall line, which extends roughly from Galveston, Tex., through St. Louis, Pittsburgh, Albany, N. Y., and on to northeastern Maine. On the

map showing eight years' service, however, the tracks with less than 25% renewals, or the "successful" tests, are numerous near this 40-in. rainfall line, while seven out of a total of 13 "failures" are south or east of this line. Four "successful" tests are also located south and east of the line.

The data as plotted on these maps, while rather meager, indicate in a general way that the arid Western states, and the Central, Atlantic Coast and New England states north of the 40-in. rainfall line form a definite area where cross-ties treated with straight zinc chloride may be expected to give from eight to ten years' service. It is felt that the line might well be extended in its central part to include all the area north and west of the Ohio River drainage area, but sufficient data are not available to support this opinion.

Construction Camp Community Association Like Commission Government

TAYLORSVILLE, the camp community created by the construction forces of the Taylorsville Dam of the Miami Conservancy District, near Dayton, Ohio, has adopted a self-government plan modeled on commission government. The plan was initiated Nov. 29, 1918, by the organization of the Taylorsville Community Association and the adoption of a constitution. Work started with 67 members, and on Jan. 1 community government was in full operation.

All employees in the dam construction and members of their families who are over 16 years of age are eligible as members of the community association. Election is by ballot. Members pay an entrance fee of 50c., and annual dues of $1. Officers of the association are five commissioners who are elected from members in good standing who have resided at least three months at the dam site. Commissioners serve six months. The one receiving the largest number of votes becomes chairman and designates the heads of four departments from the commissioners elected. Each works through committees appointed by the commission. The present incumbents are D. D. Rogers, chairman and commissioner of social service; E. P. Come, education; F. A. Meyer, community safety; B. H. Petty, community service, and Roy Hutzelman, unassigned.

At present 13 committees are organized and at work. These include committees on schools and library, entertainment, relief, religious activities, fire prevention, law and order, health and sanitation, transportation, and gardens. Day and night schools and a Sunday school are in full operation. There is a regular program of entertainment, comprising moving pictures, concerts, lectures and dances, also provision for regular union church services.

The association meets regularly once a month and the commission meets as often as there is business to transact. Similar associations are in process of creation at the other construction camps of the flood-protection works.

Of course, it must be understood by the reader that these associations do not supersede in any way the legally constituted authorities of the minor civil divisions of the State of Ohio.

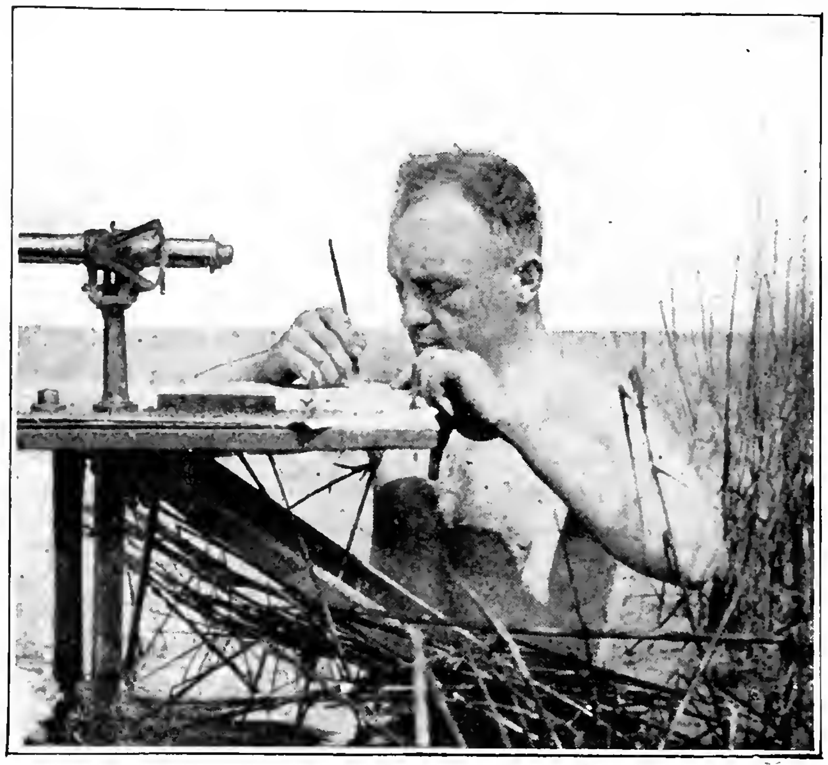
Topographic Engineers Assist in Military Mapping

Special Work of United States Geological Survey Meets Needs of War Department—School Trains New Topographers Quickly

By R. B. Marshall

Major, Engineers, United States Reserve, Chief Geographer, United States Geological Survey

WHEN the call for mobilization came in the spring of 1917, there was a demand from the War Department for topographic maps of our borders and our coasts. No other scientific bureau of the Government was more ready to respond to the call than the United States Geological Survey. No other single large group

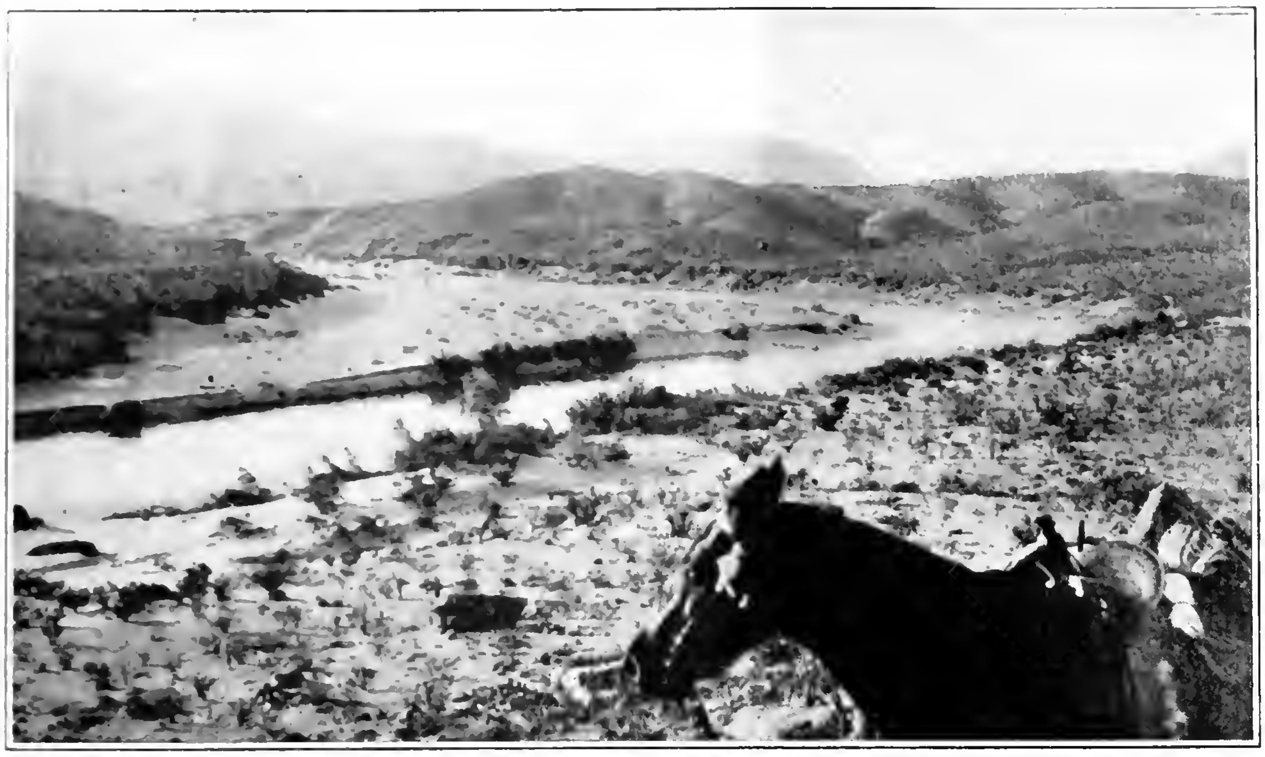


SURVEYING THE COOPER RIVER AT HIGH TIDE

of technical men in the country offered their services so early or in so large proportion to their numbers as the survey's topographic engineers.

In requesting that the Geological Survey divert its maximum activity toward topographic work, the War Department merely sought to utilize an organization already existing and fully equipped. To provide further support for this work continuously throughout the year, it allotted practically all its appropriations for topographic surveys, and Congress appropriated large additional sums for military mapping. In order that the department might exercise full authority over the plans for this work, Geological Survey men, as fast as commissioned in the Reserve Corps, have been detailed to report to the director of the survey "for duty in connection with military mapping now being done for the War Department." Thus the organization for topographic work is essentially military, the former chief topographer being now a major in charge of all Geological Survey topographic work under the War Department, and practically all his division-staff assistants and many of the topographic engineers are commissioned men.

When Villa raided Columbus, N. M., and Pershing struck off southward through Mexico, and when bandits ventured into the "big bend" country of southern Texas, there were no accurate maps of those areas for ref-



COUNTRY RECENTLY MAPPED ALONG THE RIO GRANDE RIVER

erence. Today such maps exist, and many more maps of areas along the border are ready and in the making. There was no delay when the need came for men both trained in topographic engineering, inured to the life of the desert, the swamp or the mountain fastness, and equipped to serve far from base, in country lacking in water and fuel.

It was only necessary to divert to new fields men who had had years of topographic experience in all sorts of country and climate. When, therefore, the request came overnight for such mapping, in two days parties fully organized were on their way to new stations on our coasts and borders. The areas mapped by these military surveys from Apr. 1, 1917, to Feb. 1, 1918, aggregate 23,552 square miles.

The organization and field methods of any one of these parties thus spread out along the Mexican border in several states are typical. The unit of survey is a 15-min. "quadrangle," an area measuring 15 min. in latitude and in longitude. An experienced Geological Survey topographic engineer is the party chief and is assisted by two or three associates; each of these men is individually responsible for the mapping of the portion of the quadrangle assigned to him. Scientific field assistants, recorders and rodmen complete the technical organization, and these are supplemented by the necessary teamsters, cooks and other helpers.

Transportation to and from the railroad base, perhaps 50 to 70 miles distant, is furnished by Army auto trucks and Army drivers. The men live in tents and travel to and from the day's work in the saddle, for roads are few and cross-country travel is customary. The motor trucks maintain the necessary subsistence and forage, but the camp must find such fuel as the country affords, or even pack water to a camp that is dry. This latter condition is frequently met, for the country is largely desert or "bad lands" and most of the streams are intermittent, such as are found where the annual rainfall rarely exceeds 10 in. Water is obtained from deep wells sunk at much expense by cattlemen, and also from surface "tanks" which impound the run-off resulting from torrential rains. As the work progresses camp is moved by the supply trucks.

In advance of the detailed topographic mapping smaller control parties carry triangulation and primary levels over the areas to be mapped, and the results of this control are computed for the immediate use of the main camps that are to follow. Mapping is done by the plane-table method, supplemented by the plane-table and stadia along the roads or trails and in the less exposed lowlands. The mapping also includes a complete classification of the land as to woodland, brush, water-supply and other features, so as to yield a complete inventory of the physical and economic aspects of these parts of our border. The topographic engineer is thus a pioneer also; those who follow him need not to ask or wonder what it is like "beyond," for his map will tell.

To prepare the field sheets for reproduction and immediate printing, a largely augmented force of draftsmen, of which women are forming an increasing number, has been organized at the Washington office. All field data are sent there as fast as they are completed. The resulting topographic maps are photolithographed in colors for the immediate use of the War Department. They are published on a scale of approximately 1 in to 1 mile, and with a contour interval of 10 to 50 ft., the interval employed depending on the surface relief.

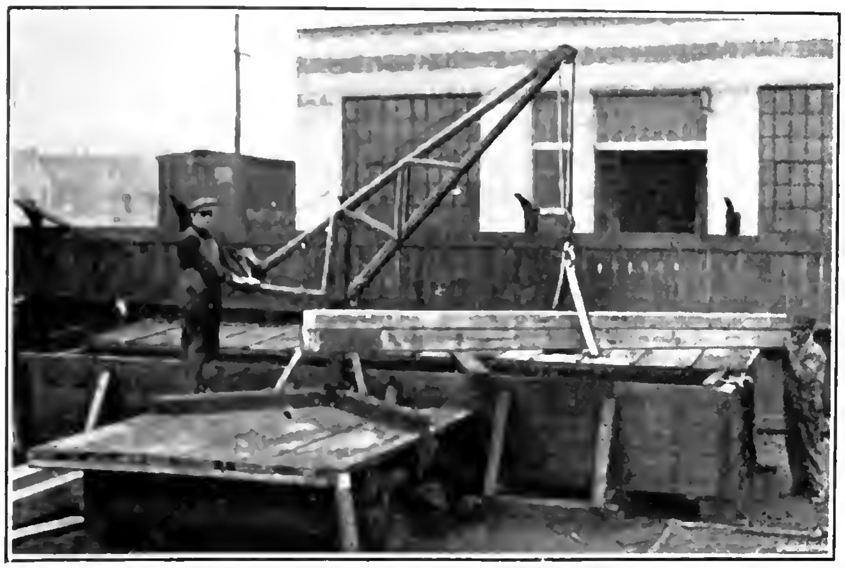
In order to maintain this force of engineers, to offset the detail of topographic officers to France on the one hand and the increasing war demands for topographic mapping at home on the other, some fifty officers, not heretofore connected with the Survey, were detailed to it from the Engineer Officers' Reserve Corps. A training school for topographers also was established. The officers detailed from the Reserve Corps were sent direct to the parties already in the field, for gradual training in the topographic work. The training school gave candidates about a month's actual field experience in a day "camp," established just outside of Washington, the men returning to the city each night as contact with office headquarters is thought to be essential to give the training its full value.

Permission having been obtained to appoint topographic field assistants without recourse to the Civil Service Commission, and without establishing a status in the classified service, about 100 such men were appointed. Most of them were obtained from the technical schools. After about a month's observation and training they were detailed to the field parties where they were most needed or where their special fitness indicated that they might be most useful. Most of these men were subject to the draft, and some were called. Others have had opportunity to enlist or to be inducted into engineering regiments where their training was needed, and they served largely as assistants to former Survey men who held engineer commissions.

Non-Pressure Treatment of Wood for Buildings

Applying Preservative at Site by Simple Processes Prevents Decay at Low Cost and Allows Use of Local Supplies

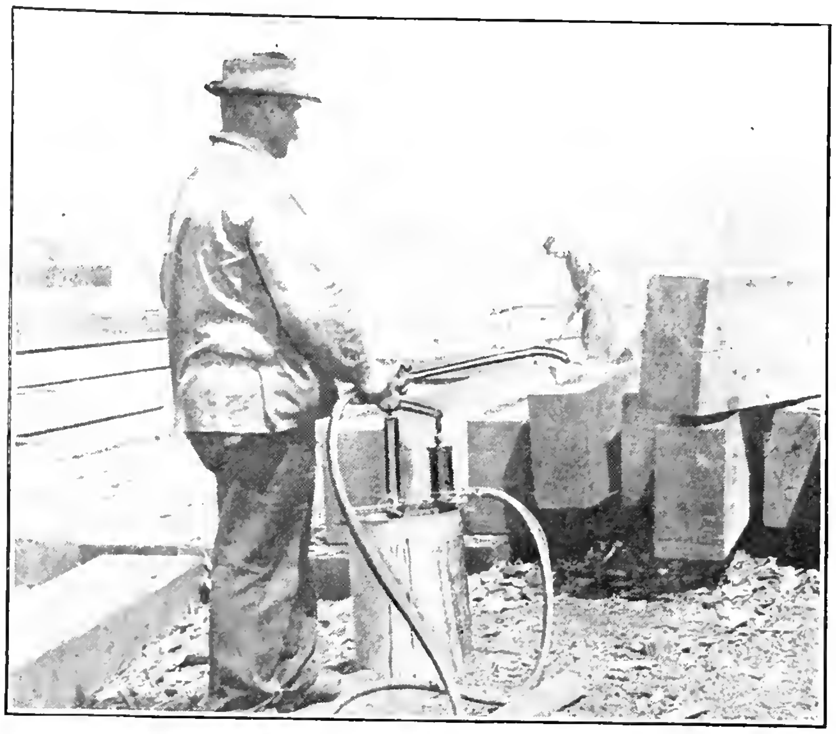
OPPORTUNITIES for extending the use of creosoted timber in the construction and repair of industrial buildings and structures, by wider use of the simpler and cheaper methods of treatment which give a sufficient degree of protection and which can be applied at the site without elaborate or expensive plant, are indicated in information compiled recently by Kurt C. Barth for the Barrett Co., Chicago. While it is admitted that the pressure or closed-tank process gives the most efficient results and the deepest penetration, its cost may be prohibitive when the amount of timber treated is comparatively small, when heavy treatment is not essential, when the buildings must be of low cost, or where distance from a treating plant would involve high freight charges on the treated timber.



SMALL TANK AND HAND CRANE FOR TREATING TIMBER

Non-pressure processes which can be employed at any point and are effective in retarding decay are shown to be applicable under the above conditions and to have been used with success on timber for mills, mines, industrial buildings, coal and gravel bins, dwellings and other structures. They are of two classes, the open-tank treatment and surface treatment. For the open-tank process the framed and bored timbers are immersed first in a bath of refined creosote oil having a temperature of 150° F. to 200° F., and are then transferred to another bath in which the oil is not over 100° F. The cooling effect, following the hot bath, results in a condensation of the heated air and moisture which assists the atmospheric pressure and capillary attraction in causing penetration of the oil.

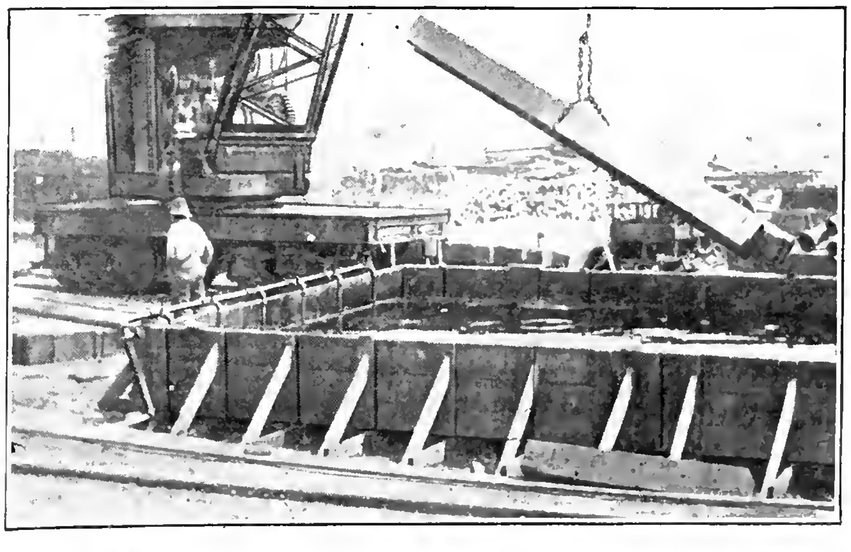
The time is the same for each bath, and depends upon the kind of wood and the size of the piece. One hour per inch of maximum thickness is the average for close-grained woods, and 15 to 30 minutes per inch for species more susceptible to treatment. For large sticks, however, the one bath may serve both purposes, the timber being left immersed and the liquid allowed to cool after the required period for the hot treatment. For planks and small pieces the hot bath may be sufficient. Loblolly pine has absorbed 8 lb. of oil per cubic foot after one hour in the hot bath. Large yellow-pine sticks absorbed 10 lb. per cubic foot after being in hot oil for six hours and then left for 12 hours while the liquid was cooling.



APPLYING PRESERVATIVE TO TIMBERS BY SPRAYING

Surface treatment with oil may be effected by means of a brush or mop, a spraying device, or by dipping, the last named being a modification of the open-tank process. Heated refined oil is used in all cases. Two coats are required for brush application, while spraying with one coat is said to give better results besides requiring less time, material and labor. All framing and boring must be done before treatment, so as to avoid removal of any of the treated surface wood. The brush and spray methods can be applied to wood after erection.

Investigations show that timber treated by these simple processes has given particularly good results in the roofs of paper mills and weaving sheds, where the high degree of humidity is conducive to decay. While the life of the best grades of untreated timber under such conditions is seldom more than nine years, and often only four years, roofs built of treated timber have been found in good condition after seven to nine years' service.



LOCOMOTIVE CRANE HANDLES LARGE TIMBERS AT TREATING TANK

In one case the 2 x 6-in. white-pine roof covering of a paper-mill machine room built in 1900 was removed in 1908 on account of decay. It was replaced by douglas fir, and hot preservative was poured upon the finished roof, which was found to be in good condition eight

years later. In a similar machine room a roof sheathing of Norway pine, painted with white lead and oil on the inside, was removed in three years on account of decay. The new Norway pine roofing received two brush coats of coal-tar preservative before being set in place, and this roofing gave 14 years of service. A floor of brush-treated yellow pine, alternately wet and dry but protected from mechanical wear by steel plates, was in good condition after five years, although an untreated part of the floor had begun to fail from decay.

Where numercus low-priced dwellings are to be erected, as for workmen's houses or suburban development, it is claimed that timber treated by these simpler processes will prove economical, by permitting the use of cheaper and less durable kinds of lumber and reducing the cost of painting, since creosote applied as a preservative may serve also in place of paint or stain. For such work the open-tank process is considered desirable, the tank being installed on the site and the treated timber stacked to dry for a few days before being used, the time depending upon the atmospheric conditions. The treatment may be applied to all lumber used in the first-floor framing and porches, to the shingles and to the fence posts and boards.

Philippine Water-Supplies Get Strict Sanitary Supervision

Good Water Reduces Death Rate 50 Per Cent—Government Encourages Wells by Paying Two-Thirds Cost—Amoebæ Normally in Water Not Removed by Filtration but Not Disease Producers

By George W. Heise

Saltville, Va., formerly Chief of the Section of Water Analysis, Bureau of Science, Philippine Islands

Before American occupation of the Philippine Islands a vast majority of the 8,000,000 inhabitants was dependent upon streams or shallow dug wells for its water-supply. Primitive methods of living and lack of sanitary facilities and sewerage systems made pollution of the supply inevitable, with detriment to the public health. Torrential rains of the wet season also caused periodical contamination, by washing débris into the water courses and wells. The only municipal system worthy of the name, that of the City of Manila (installed in 1882), derived its water from a river which drained a thickly inhabited watershed and was in effect the sewerage system for this area.

Spanish Efforts Not Successful

Attempts of the Spanish to secure potable water for towns located on mountain sides deserve mention. In these installations, some of which are still in use, water from springs located above the town was carried in open runways or ditches to the edge of the town, whence it was distributed through open laterals. As these ditches and laterals served as convenient places for washing clothes and as sewers (and in many cases are still used thus), these attempts to improve the water-supply could not be regarded as an unqualified success.

Even the water from sources of naturally potable supplies, such as certain springs, was frequently contaminated through careless handling and improper methods of storing. Under such conditions, it is hardly surprising that the Filipinos as a whole were weakened by disease, that dysentery and other intestinal illnesses were common, and that devastating epidemics of cholera occurred repeatedly. The state of affairs may be inferred from the fact that as late as 1909, after great improvements had been made, it was estimated that from 80 to 90% of the Filipinos were afflicted with intestinal parasites. In the low lands the temperature in general is over 85° F., rarely going above 90° or below 65, while the humidity is high. Temperature of surface water averages about 80 deg. Conditions are therefore relatively favorable for bacterial growth.

With the establishment of civil government, after the American occupation, much work was done in sanitation and the improvement of public water-supplies. The intimate connection between public health and the character of water was clearly demonstrated by the fact that in some localities the substitution of good water-supplies for the polluted sources previously in use led to a 50% reduction in the annual death rate. In Manila the installation of a new water-supply system was followed by a reduction of 66% in the annual deaths from intestinal diseases.

Construction of artesian wells was a most important factor in the improvement of existing water-supplies. Previous to American occupation there were two or three comparatively shallow flowing wells that had been constructed by the Spaniards. Drilling of artesian wells, begun by the insular Government in 1906, proceeded steadily until, at the end of 1917, about 1500 wells had been bored by the Bureau of Public Works, besides numerous wells constructed by private enterprise. For a period of years the annual Government expenditure for well drilling has been about $225,000. The drilling of wells was greatly stimulated by an act of the Philippine legislature, whereby the insular Government paid 66% of the cost of all successful wells, the municipality paying the balance, whereas the entire cost of an unsuccessful boring was borne by the Government. A well was considered unsuccessful if water was found in insufficient quantities or if analysis showed that it was not desirable for human consumption.

Water from Wells Is Satisfactory

Deep wells were generally properly constructed and tightly cased, with the tops embedded in cement. Their water, though frequently heavily mineralized, is bacterially pure and usually potable. Flowing wells are very common and are the most satisfactory, but unfortunately no attempt has been made to conserve the artesian supply, and some wells are already showing marked decrease in flow.

Deep pump wells are far less desirable. Great difficulty was experienced in securing a pump which would stand the service, as the local authorities, to

whom a well, on completion, was turned over by the insular Government, usually failed utterly to keep the equipment in repair. From personal observation in a number of provinces it may be stated that between 25% and 66% of the pumps were out of order or entirely inoperative all the time. Failure to drain waste water away from the well side, and use of dirty water for priming the pumps, served further to make the situation unsatisfactory.

Considerable progress was made in supplying towns with municipal water systems. In some of the larger installations (Manila, Cebu, Zamboanga) rivers from carefully guarded watersheds serve as a source of supply. In other cases springs or artesian wells are utilized. In one town, where the existing surface and underground supplies were not potable, a large rainwater cistern was constructed which supplies limited amounts of water for drinking purposes only. At the present time over 20 towns have water-supply systems in operation or under construction.

In none but the larger towns was any attempt made to supply individual houses with water. Even there the people in general were supplied, as in the smaller towns, from hydrants placed at intervals about the town, whence water was carried in 5-gal. gasoline cans, earthenware jars (ollas) or even in bamboo tubes.

The consumption per capita is relatively low, but this is of little significance in view of the scarcity of house connections and the general absence of sewerage systems. In Manila, which has the most elaborate system and where much water is used for industrial purposes, the average daily consumption is about 60 gal. per capita. In small towns, where potable water is the vital necessity, town projects have been based on an available supply as low as 10 gallons.

In only three towns is storage practiced on a large scale. As one of these has relatively small storage capacity and the other installations are comparatively recent, no great difficulties from stagnation have developed. In the isolated cases where disagreeable tastes and odors occurred, removal of the accumulations of sediment in the impounding reservoir was sufficient to restore normal conditions. Reservoirs usually must be abnormally large, since in many parts of the islands the rainfall, though high, is not distributed throughout the year, but occurs mainly during a period of about three months. Naturally, the water courses become greatly depleted during the dry season. The rainfall is 76.5 in. in Manila, on the island of Luzon, and two or three times as great in certain other islands.

Attempts to Purify Water

Some attempt has been made at water purification, principally on the Manila supply. This water is somewhat turbid and high in organic matter, and should be filtered and perhaps further purified. Sand filtration was proposed when the present system was being installed, until it was shown that amœbæ would grow through a filter. Although more recent study has shown that the omœbæ normally found in practically all tropical surface waters are not the kind that cause dysentery in man, the appropriation for an adequate filtration system has not been forthcoming. Copper-sulphate treatment was not deemed advisable, because of the excessive concentration (one part per 150,000) required to kill cholera vibrios. At the present time treatment with chloride of lime is practiced, but as the method of administration is crude and not very efficient, the water frequently acquires distinct odor and taste. Chlorination undoubtedly has effected a marked improvement in the water-supply, though the Americans, Europeans and wealthy native residents either boil the water before drinking, or, preferably, buy bottled distilled, artesian or spring water for table use.

Typhoid, dysentery and cholera are the principal water-borne diseases in the Philippines, but it is recognized that the organisms of these diseases are found in water only as the result of direct contamination. Accordingly, the best safeguards against infection are protection of the source, and measures to prevent careless handling of water after it is taken from the source.

Health Officials of the Islands

Progress has been due primarily to the coöperative efforts of three bureaus of the insular Government: Public Works, Health, and Science. The Bureau of Public Works has conducted the construction of artesian wells and water-supply systems. The Bureau of Health has established an organization which operates over the principal portion of the islands. Each province has a health officer and a corps of assistants whose work deals with matters pertaining to health and sanitation. In recent years this bureau has started a line of work which already has been productive of much good. This consists of the organization of "sanitary commissions," composed of sanitary engineers, bacteriologists, doctors and nurses. The work is intensive. A commission stays in a single town collecting vital statistics, establishing clinics and dispensaries, examining all available water-supplies and in general conducting a campaign of sanitation and education.

The Bureau of Science is the central scientific laboratory for all branches of the insular service. It has conducted the routine examinations, both chemical and biological, of sources of water, and has conducted medical surveys of certain districts with the coöperation of other bureaus. It tests every new artesian well and has conducted many investigations on water-supply problems in general.

Difficulties inherent in water examination are exaggerated in the tropics. Samples sent in for analysis are often taken improperly and are unaccompanied by necessary data concerning the source, while, owing to the climate and to difficulties of transportation, they rarely reach the central laboratory in proper condition for examination. European or American standards are of little value. The writer virtually abandoned nitrogen determinations in chemical water analysis. Colony counts on plain agar; presumptive and, if necessary, confirmatory tests for b. coli. and a test for protozoa served for the routine biological examinations. The organism of dysentery is not readily detected, and the presence of amœbæ in surface water is of little significance, as noted above.

For a field survey undertaken by the Bureau of Sience a field laboratory was devised, patterned after that of the United States Geological Survey, with which it was possible to make both chemical and bacteriological

examinations. Though lacking the refinements of laboratory analyses, the field examinations gave results superior to those usually obtained in the central laboratory, since field methods were sufficiently accurate for ordinary purposes; and as the analyst obtained his own sample he could make valuable observations regarding the nature of the source.

The water-supply situation is still very unsatisfactory, in spite of the progress which has been made. Ignorance of the first principles of sanitation, superstition regarding the use of artesian well water, and unwillingness to abandon unsafe surface supplies, are some of the unfavorable factors. Surface wells still furnish a large part of the water used for domestic purposes, although examination has shown practically all these sources to be dangerously contaminated. The average surface well is close to human habitations and is open and unprotected. Water is obtained by dipping, frequently with dirty vessels. Clothes are washed at the well side, and animals are allowed in the immediate vicinity.

In six typical towns studied by a sanitary commission only 2% of the homes were supplied with privies, of which 10% were flush closets. More than 95% of the inhabitants of these towns have been found to be infected with intestinal parasites. One of the larger cities, with a population of 50,000, is still unsupplied with a municipal water or sewerage system, although practically all available sources in that locality are unpalatable or dangerous.

The outlook for improvement of sanitary conditions is none too favorable. Capable men have not been encouraged to remain in the service, and in a large number of instances their places have been filled with comparatively untrained natives. However, the foundation for good work has been laid, much gratifying progress has been made, and it is to be hoped that further improvements will come.

Comparison of Railroad Terminal Projects at Cleveland

Relative Advantages of Lake-Front Project Decided Upon Some Years Ago and Public-Square Location Approved by Recent Vote, as Seen by Various Engineers

TWO rival railroad-terminal projects have been under discussion in Cleveland for many months past. By vote of the people Jan. 6 one of the projects was ostensibly adopted, but there remain so many legal and financial details to be settled before the project is finally approved that a résumé of the two projects, purely as solutions of a railroad-terminal problem, seems worth while.

In 1915 contracts authorized by vote of the City of Cleveland were entered into between the city and the New York Central, the Pennsylvania, the Cleveland & Pittsburgh and the Big Four R.Rs., whereby these railroads agreed to build a union station on the lake front forming the northerly end of the elaborate public-building group which had been started by studies in 1903. Various agreements as to exchange of property and improvement costs were fixed in the contract, which further stipulated that actual work should begin within six months after the deeds to the property had been delivered. Such delivery has never been made. In 1912 the Cleveland & Youngstown R.R. was empowered by the city council to operate a railroad across certain streets in Cleveland, and in 1917 this railroad, together with the Wheeling & Lake Erie, the Erie, the Baltimore & Ohio, and the Nickel Plate, which latter had been purchased by the Cleveland & Youngstown, prepared plans for a stub-end passenger station on the Cuyahoga River Valley just south and west of the Public Square. Early in 1918 these plans were submitted to the United States Railroad Administration. In the discussion which followed it was suggested by the regional director that the plans be changed from a stub-end to a through passenger station, to be used by all the railroads entering the city. On Aug. 17, 1918, the plan and report were adopted by the representatives of the seven railroads interested, which include the railroads which had hitherto agreed to build a union station on the lake front. A company was therefore organized, known as the Cleveland Union Terminals Co., to build the union station on the Public Square, and an ordinance was adopted by the city council and approved Jan. 6, by a vote of 31,000 to 20,000 (as noted in *Engineering News-Record* of Jan. 16, p. 165), authorized its construction.

Previous to the vote Jan. 6, however, a lively controversy arose in the city as to the desirability of the two sites, and the Chamber of Commerce retained Lieut. Col. Bion J. Arnold to report on their relative advantages. Following Colonel Arnold's report a statement was made by W. E. Pease, engineer for the Cleveland Union Terminals Co., and by the Board of Supervision for Public Buildings and Grounds, which is the body having control of the public-building group plan for which Cleveland has become so noted. All of these reports have been made up by the Cleveland Chamber of Commerce under one cover, and they give a very clear exposition of a difficult problem, and one which by no means is settled by the recent vote.

The three maps given herewith show the present and prospective railway terminal situations. One map gives the present location of lines entering the city; the second, the proposed lake-front union-station scheme, and the third, the proposed Public-Square union-station plan. The lake-front scheme retains the present lake-shore lines in approximately their present location, but provides for expansion, as noted in Colonel Arnold's report. In the original scheme, some other arrangement of terminals had to be provided for all the railroads now entering the city from the south, but the drawing gives the possible entrance of the Cleveland & Youngstown and other lines via the Cuyahoga Valley.

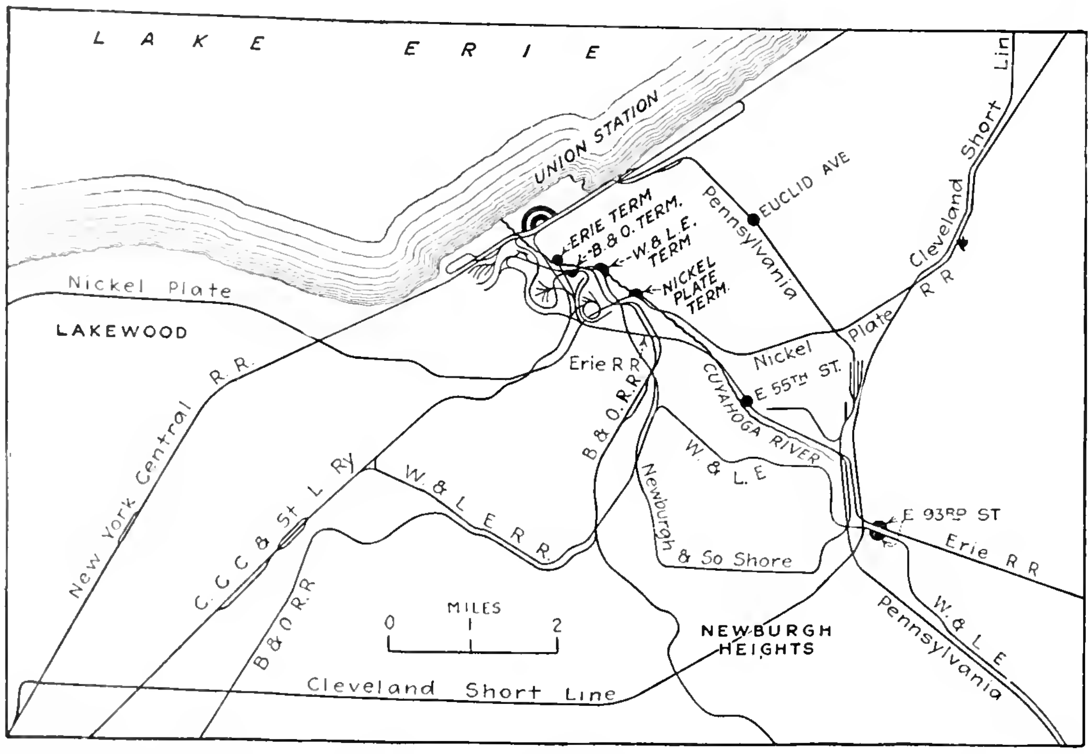
The plaza scheme involves the construction of a through passenger station southwest of the Public

Square, with railroads entering via the Cuyahoga Valley. Provision is made for two train levels in the station, the upper level to be used for express and limited train service, and the lower level for suburban and local trains. Interurban tracks would also be laid alongside of the main-line tracks, thus removing a number of present tracks from the city streets. Provision is furthermore made for a subway connection to the Public Square, in which now all the city's trolleys center. Behind the main passenger station there would be laid out a number of freight terminals, with adjacent warehouses. The present lake-shore roads would have to be relocated as shown on the map in order to bring their passenger traffic into the city via the valley, retaining the shore line for freight use.

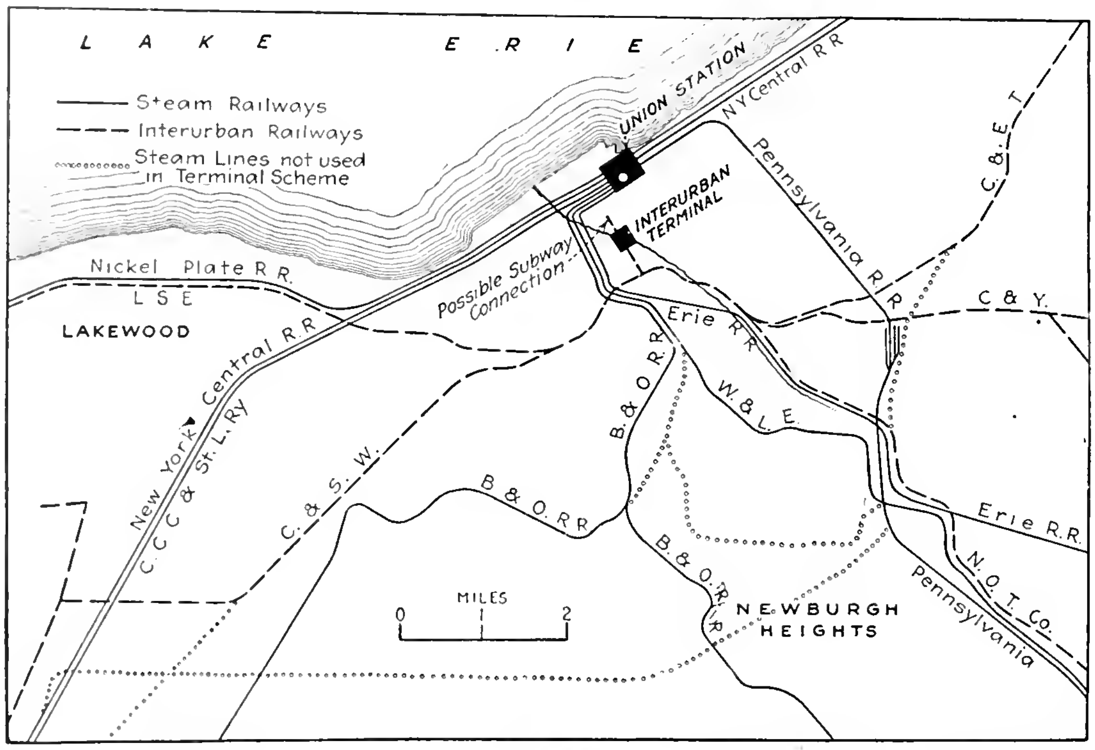
Five terminal stations now existing would be consolidated into one union station, in either case. Of these five, the largest is the old lake-front union station, used by the Pennsylvania and the New York Central lines. This, according to report, handles 85% of the total ticket sales and 66% of the daily total of 156 trains. Only 36 of these trains pass the most congested part of the New York Central main line, noted below. The other terminal stations are those of the Erie, the Baltimore & Ohio, the Wheeling & Lake Erie and the New York, Chicago & St. Louis.

A straight and direct route for the principal lines is provided by the lake-front site, with other lines coming in from the side, along the Cuyahoga Valley. The Public-Square site, however, necessitates approach by a sinuous location, with the union station placed at the apex of a V, so that entrance curves at each end are unavoidable. Interurban lines by this latter project would be transferred from streets and highways to the railways' right-of-way and brought into the lower level of the station.

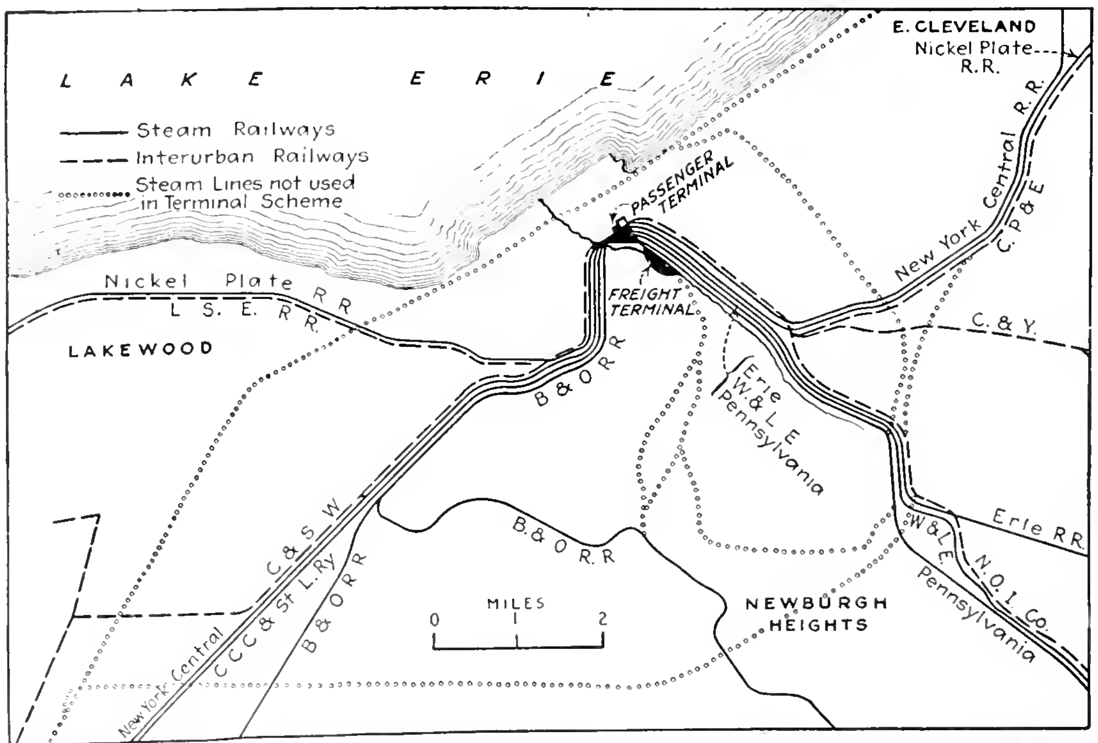
The main conclusion of Colonel Arnold's report is that the whole subject should be thrown open to further study. Three subjects submitted to him as the basis of his report were as follows: A comparison of the two projects; the possibilities of developing the lake-front site to meet the future requirements of the city; and the likelihood that the Public-Square project would cause extreme traffic congestion on the square. Comparison of



PRESENT RAILWAY SYSTEM OF CLEVELAND, OHIO, HAS FIVE TERMINAL STATIONS



MAP SHOWS POSSIBILITIES OF ACCOMMODATING ALL LINES AT A UNION STATION ON THE LAKE FRONT



MAP SHOWS PROJECT FOR DIVERTING ALL LINES TO A CENTRAL UNION STATION ON THE PUBLIC SQUARE

the projects is made on their merits, and does not include estimates of cost, although it is shown that very high cost of land is involved in the central project.

Reconstruction of a lake-front union station to accommodate not only the roads now using this site, but all the steam railways entering Cleveland, is recommended on account of the possibilities of readjustment of freight and passenger terminals, the space available and the general facility of access. Conditions of grades and topography favor such development at minimum capital expenditure.

Terminal development at the lake front could proceed even now on a temporary two-level plan, as pointed out by Colonel Arnold, the present roads on this location using the permanent upper level and the roads coming in along the Cuyahoga Valley occupying the lower level. If electrification were feasible immediately the lower lines could be placed beneath the upper deck, but, failing this, they would be operated alongside of the high-level lines. When the Cuyahoga River is straightened, as now proposed, the Big Four trunk-line entrance through the valley would be elevated, all main lines then using the upper level of the station and the lower lines being reserved for service tracks or other purposes.

Lake-Front and Central Sites Are Compared

Critical comparison of the two sites is given in some detail in Colonel Arnold's report. Area available for development at the lake front is practically unlimited. Plans for the Public-Square site provide for 24 tracks ultimately, which in the author's opinion represents the limit of possibility at this site for steam-railway purposes. He considers this sufficient for 15 or 20 years, provided that extensive commuter traffic does not develop as in New York, Chicago, Pittsburgh and other cities. From his investigations, however, it seems possible that such traffic may develop in Cleveland to the extent of requiring at least half of the station capacity during the rush hours. With the Public-Square station admitting of no further expansion, the only remedy would be to utilize some of its tracks on the lower deck, provided that the electric interurban traffic on this deck could be handled in less space than originally intended for that purpose.

Sharply curved entrances form a distinctly unfortunate feature of the Public-Square site, but are unavoidable here on account of the location. Thus, while the average platform length is about 1000 ft. (13 cars) the average length on tangent is only 600 ft. (eight cars). There is no such limitation at the lake-front site, which is on a straight line.

Cost of the Public-Square station is bound to be very high for the amount of trackage available, in Colonel Arnold's opinion, owing not only to the high commercial value of the land, but also to street reconstruction and the demolition of existing structures. In fact, nearly half the cost of this terminal appears to be in land and right-of-way. Most of the land required for the lake-front site is owned by the railways, and the balance can be acquired at a very low rate, compared with the other project, so that, Colonel Arnold estimates, the total cost of site might not exceed 25 or 20% of that of the Public-Square site.

Approaches and grades also appear decidedly favorable to the lake-front site, as the location is straight and the present maximum grade of 0.75% for five miles west of the river could be reduced to 0.56% for at least 1¼ miles. The other location is sharply curved, and would have short grades of 1.1% on the east and 0.72% on the west approach. Furthermore, the latter would require expensive grade improvement on the east and a long cut on the west about 45 ft. deep, with a ¾-mile viaduct across the valley.

Rerouting of trains would enable the present New York Central main line on the lake front to accommodate through traffic for some time. Both projects provide for four-track approaches at present, with a future increase to six tracks.

Obstruction to the above New York Central main line, due to certain yards and industries, which obstruction has been emphasized as a serious objection, is only a temporary difficulty and can be remedied, according to Colonel Arnold. He shows that removal of the yards in question is proposed already, while the city's policy of encouraging industries to transfer to points where ample space is available at low cost will result in relieving this part of the congestion automatically.

In facility of access for the public the Public-Square site has an advantage as long as this point remains as the commercial center. But eastward extension of the retail business section seems probable, according to the report, so that this advantage might be reduced in the future. Establishment of through lines of surface and subway local transit might place the lake-front site relatively at a disadvantage, but Colonel Arnold points out that frequent station service can be established, and that while concentration of local transit service at a large railway station is primarily desirable it often produces undesirable results. The lake-front site has the advantage of numerous wide streets, as compared with the cramped and detoured street system proposed around the Public-Square station. It is urged that subsurface levels for this latter station should not be developed without full consideration of the possibilities of future rapid-transit subway development, to which such station sublevels might be an obstruction if not planned with such subways in view.

Electrification of Prime Importance

Electrification is of maximum importance in the Public-Square project, because of high-grade commercial property in proximity to the parking space for the locomotives. It is imperative, in fact, on account of the proposed development of buildings over the station site. This condition does not affect the lake-front site, although Colonel Arnold points out that the station should be designed with a view to future electrification. Location of coach yards and engine terminals is favorable to the lake-front site, as in the other case these facilities would be from two to five miles distant, necessitating considerable dead mileage.

For through-freight service Colonel Arnold suggests two alternative high-level, low-grade routes, independent of the New York Central main line on the lake front and requiring but little construction work. This, he considers, would give a better balance of traffic than the diversion of all passenger traffic from the direct

lake-front route to the circuitous route leading to a central station, and of all eastbound freight traffic to the existing belt line.

The freight-terminal facilities as provided by the Public-Square project are unsatisfactory in their relation to the city, in Colonel Arnold's opinion. While the terminal itself is well planned, it gives undue concentration at a point where only a few thoroughfares are available for distributing the team traffic. It would involve a large amount of trucking across the retail district to the warehouse and wholesale district, while all the trucking to and from a yard handling 500 to 1000 cars daily must concentrate at the only viaduct connecting the east and south sides. At the lake-front site, freight-house and team-track facilities of ample capacity can be provided at such elevation as to reach the streets by grades of 3.5 to 3.7 per cent. This location also would avoid trucking across the retail district.

Facilities for interurban package freight are recommended in the report. In the Public-Square project some provision is made for handling farm products on the lower deck of the passenger station, but Colonel Arnold considers that good facilities for handling electric freight and express matter at the freight houses should be provided, in order to remove traffic from the most congested point of the downtown streets.

The removal of electric interurban traffic from streets and highways is provided in the Public-Square project, to the extent of 46 miles within the city limits and 60 miles within the Cleveland district, but this will require the construction of about 13 miles of new line for the necessary connections. While this is advantageous to the city, according to Colonel Arnold, the cost to the electric lines in traffic readjustment, new track-entrance facilities and cost of terminal service appears to be indefinite. Ability of the interurban lines to pay their share of the cost is questioned.

Under the lake-front plan the interurban lines would have to be accommodated in a separate terminal (as originally considered in the Cleveland & Youngstown ordinance), connecting with a possible future subway in the Public Square. Colonel Arnold suggests that they might be accommodated at considerably less expense in a double-deck terminal occupying about the site of the present station of the Wheeling & Lake Erie Railroad.

Congestion of Street Traffic

Serious traffic congestion in the Public Square and adjacent thoroughfares, without rapid-transit subways, would result from the establishment of a single union railway terminal at this point, in Colonel Arnold's opinion. Eventually such a concentration of railway, interurban and local traffic would necessitate three successive developments: The rerouting of surface cars; the provision of rapid-transit subways and connecting viaducts across the Cuyahoga Valley to relieve and by-pass the Public Square traffic; and, very probably, the construction of a second union station on some other site to accommodate the long-haul steam traffic crowded out by the growth of suburban electric traffic.

In giving this opinion, Colonel Arnold considers the desirability of decentralizing intensive commercial development in accordance with modern city-planning movements. He considers also "such inefficient and improper concentration" as has occurred in the downtown districts of New York, Chicago and other cities. While various expedients might be provided to relieve the congestion, they can be regarded only as temporary, even with lavish expenditure of capital and engineering skill.

Viewed broadly, says Colonel Arnold, the question of congestion calls for a distinctly unfavorable reply if transit development is to continue along present lines. The reply can be favorable only if extensive capital investment is assumed to be forthcoming for such complementary undertakings as subways and viaducts. Construction of such works would be imposed upon the city, and would not be a part of the terminal project.

Contentions of Union Station Advocates

About the time when Colonel Arnold's report was made, the Board of Supervision for Public Buildings and Grounds made a report to the Chamber of Commerce in which it urged strongly that further consideration of the proposed lake-shore project be given. It is the feeling of this board that the removal of the railway station from the lake-shore end of the Mall will be a serious detriment to the proper development of the new building plan, and would, in addition, force upon the city the financial obligation of supplying something to take the place of the station, which was a necessary architectural feature of the group.

In partial answer to the Board of Supervision and to Colonel Arnold, the Cleveland Union Terminals Co. says that the original scheme for the group plan did not include a railway station at the lake end of the Mall, and that the station was placed there only after it was thought there was no other place for it. The terminals company passes over Colonel Arnold's report with the mere statement that it must be an academic dissertation upon the comparative merits of the two projects, because of his admited failure, for want of time, to make the preliminary studies of the problem which he states are so vitally necessary. The company asserts that the union terminal would reduce the average running time of the suburban roads entering the city at least 30 min. and remove the suburban cars from the city streets. It would (1) provide Cleveland with the advantages of commuter service; (2) wipe out the bad architectural conditions existing on the south side of the Public Square; (3) provide a magnificent architectural development, involving perhaps in its ultimate cost an expenditure of $50,000,000, and (4) remove from the group plan a building to which its originators earnestly objected at the start, and render the Plaza or Mall available for more appropriate architectural treatment.

Road Engineers Will Be Wanted in Alabama

An insufficient supply of field engineers has hampered the supervision of road work by the Alabama State Highway Commission. In its latest annual report. dated Nov. 2, 1918, the commission states that with the steady increase of Federal-aid work it will be absolutely necessary to have additional engineering assistance, to keep faith with the United States Government by seeing that this work is executed properly.

Design and Operation of Fort Myer Sewage-Treatment Plant

Pioneer Among Standard Camp Sewage-Works Consists of One-Story Tank, Dosing Chamber and Sprinkling Filters—Low First Costs—Produces Good Effluent

By Leonard S. Doten
Major, Quartermaster Corps, Sanitation Section, Engineering Branch, Construction Division of the Army, War Department, Washington, D. C.

THE officers' training camp at Fort Myer, Virginia, was one of the first military camps constructed by the War Department following the declaration of war. As constructed this camp had a capacity of 2500 men. Work was started in the latter part of April, 1917, and completed on May 14.

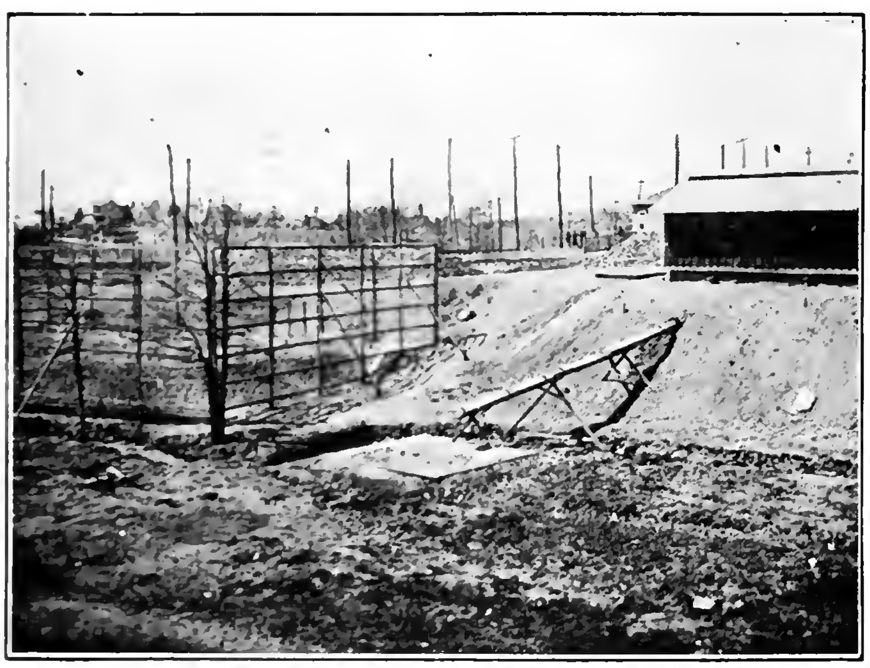
The writer was called upon to design a complete water-carriage sewerage system for this camp. The conclusion was soon reached, after an investigation of conditions at the camp site, that to dispose of the sewage adequately it would be necessary to construct either a pumping station with a long force main, or a sewage-treatment plant. Owing to the fact that the time was limited for completing the system, and in consideration of the difficulty of obtaining suitable pumping equipment, it was decided to construct a sewage-treatment plant near the southern limit of the camp, and to discharge the effluent therefrom into a small watercourse leading away from the camp site. The sewers and treatment works were built in about three weeks and put in operation on May 14, 1917, the date of opening the camp.

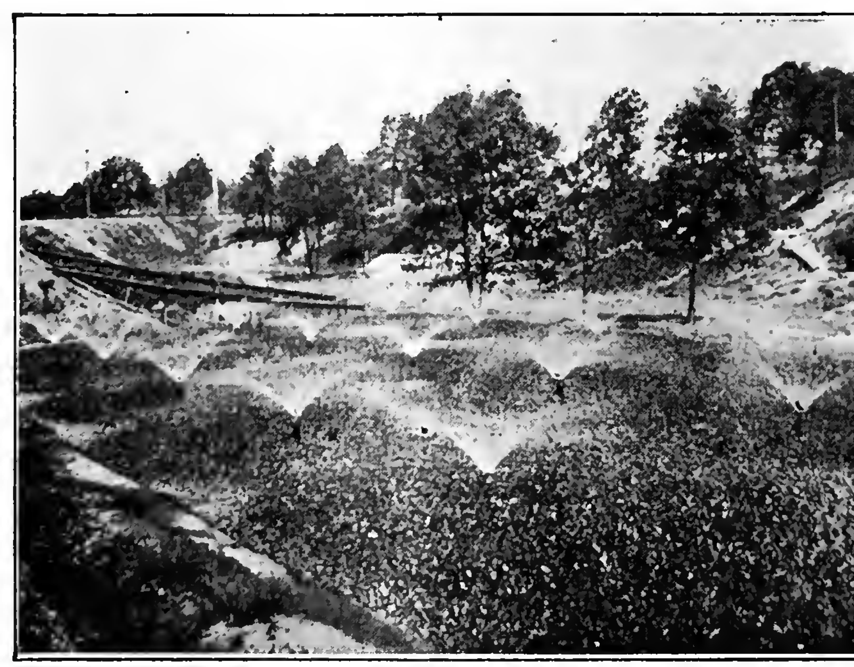
The treatment works consist of a settling and sludge-digestion tank, a siphon chamber and a sprinkling filter. The design of the tank was somewhat similar to that of several tanks which had previously been designed by the writer for military post purposes, but was much simpler in details of construction. It has a gross capacity of 26,000 gal., and is divided into three compartments of equal size. The baffles are much deeper than were those used in previous designs. The filter is 5 ft. deep and has an effective area of approximately 3000 square feet.

The entire plant was designed on the most economical lines possible. Many features which had previously been considered essential by the writer and other designing engineers for municipal plants were omitted. All filter cross-sections were identical, and the concrete in the retaining walls and the underdrainage was reduced to a minimum. Advantage was also taken of the conformation of the site to reduce the amount of excavation to the lowest possible limit. The plant, which was designed for a population of about 2000, cost only some $8000, although crushed rock delivered at the site cost $3.10 per cubic yard.

Soon after the completion of this plant the writer prepared typical drawings for sewage-treatment plants suitable for camps accommodating from one regiment to a division. The designs were similar to that of the Fort Myer plant, except certain details of baffles. Later, when the Cantonment Division (now the Construction Division) was organized, and the writer was placed in charge of sewerage work, this type of plant was adopted as the standard for use at all cantonments and camps. Carefully prepared estimates of the cost of tanks showed a great saving in cost of construction over Imhoff tanks of equal capacity, the average cost being approximately one-third that of the latter type. Another factor of great importance was the time saved in construction. Furthermore, it had the advantage of being simpler to operate than the deep separate digestion-chamber type and more suitable for handling the sewage, which was fresh and uncomminuted and therefore characteristic of camp and institutional sewage.

It has been the established practice of the Construction Division since April, 1918, to install large grease traps of special design on all kitchen sewer connections in new camps, and to replace with the same the small, vitrified-clay traps originally installed in old





THE COVERED SETTLING TANK IS ABOVE AND NEAR THE WIRE-FENCED SPRINKLING FILTER

camps. The Fort Myer system was equipped with these traps this season. As a result, the grease load on the sewage-disposal plant has been greatly lessened, giving the plant additional capacity.

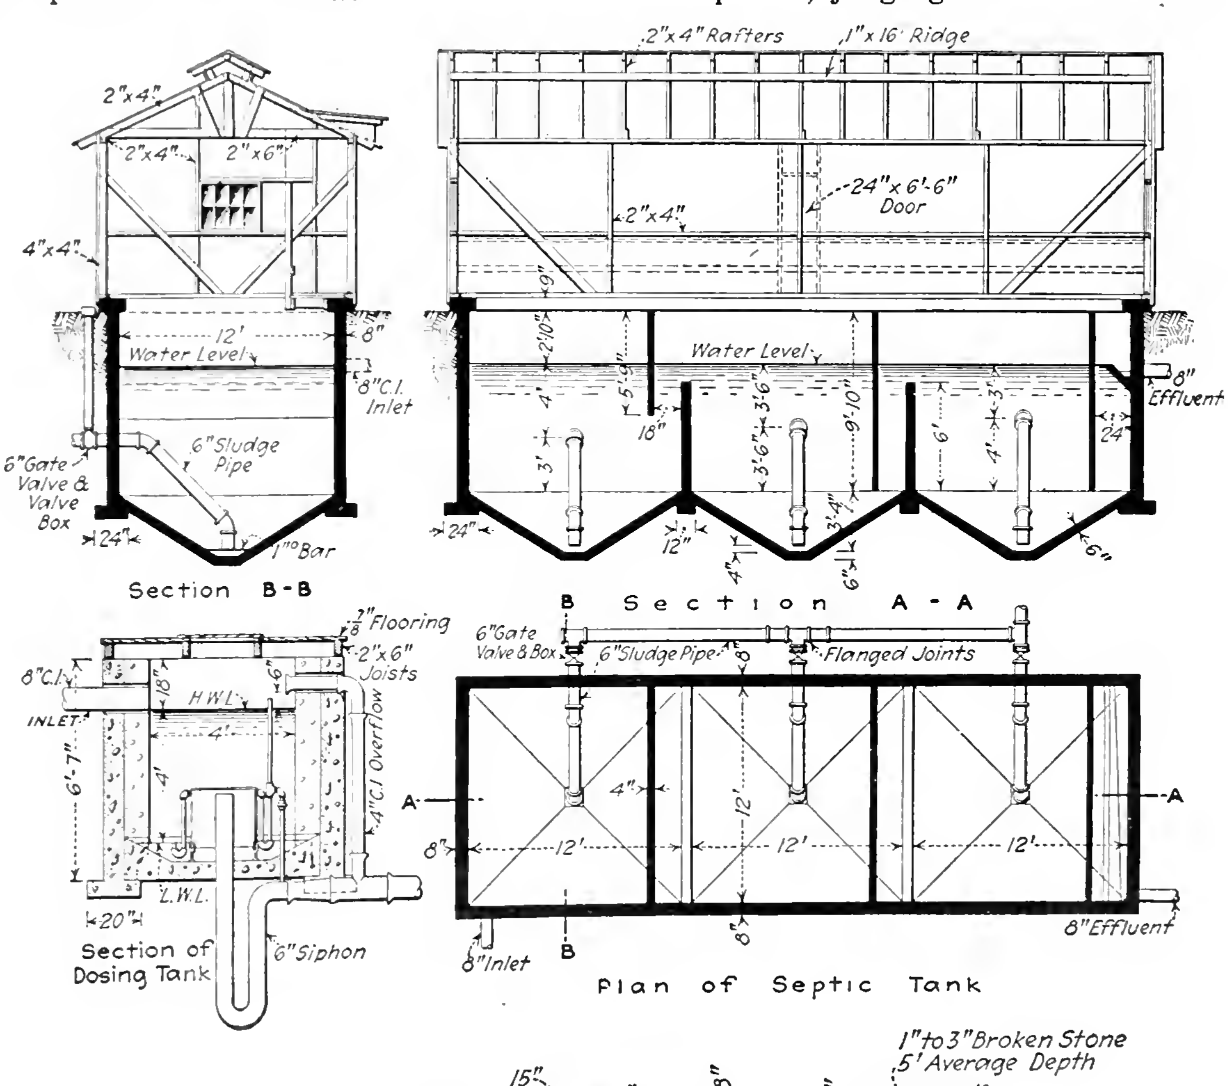
The new grease traps have a capacity of approximately two-thirds of a gallon per capita and are designed to avoid as far as possible the retention of settleable solids. It has been found possible to recover grease ranging in amount from 50 to 75 lb. per company per week. It is estimated that the grease recovered by means of these traps will be over 12 lb. per man per year. At the present time, this grease is being rendered and made into soap for camp use. At the cantonments, grease and many other wastes are sold under contract.

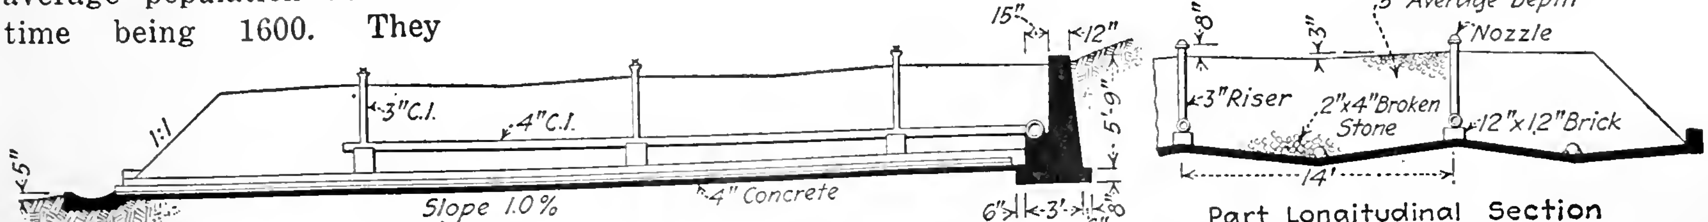
The plant has been in continuous operation since its completion, handling the sewage from a population generally ranging from about 1500 to 2200.

Although located only about 150 ft. from the nearest barracks building and a little over 100 ft. from a small railway station, no nuisance has resulted. The tank was slow in "ripening," due undoubtedly to the large amount of grease which was later found to be characteristic of the sewage at the cantonments. As a result of this, it was found necessary, about four months after the tank was placed in commission, to remove a part of the accumulated solids in the first compartment and to make certain structural alterations in the tank. (The sections shown herewith represent the tank as it now stands.) The tank since that date has developed normally, yielding at all times a very satisfactory effluent and a well digested, rapid-drying, odorless sludge. There was one period of over four months during which almost no attention was given to the plant, the doors of the tank not even having been opened for inspection. The filter continued to operate satisfactorily during this period, which extended from approximately Oct. 1 to the middle of February. Ice formed to a depth of about 1 ft. on certain portions of the filter during the winter. In April, 1918, Capt. E. J. Tucker, Sanitary Corps, U. S. A., assisted by First Lieut. J. J. Newman, of the same corps, conducted a series of tests on the plant, the average population at that time being 1600. They made analyses of raw sewage, tank effluent and filter effluent. The tests were continued from April 18 to 24, inclusive. The data thus obtained confirmed the writer's opinion relative to the excessive quantities of grease carried in cantonment sewage. It also showed that the sewage contained much larger quantities of suspended organic matter than had previously been supposed. It was found that the average sewage flow was approximately 47 gal. per capita per day. The average grease content, as shown by these tests, was about 115 ppm.; total solids, 1169; suspended organic matter, 571. Although the average detention period was approximately 4½ hours, 72% of all suspended organic matter was removed by the tank. The filter yielded a uniformly satisfactory effluent, although operating most of the time at the rate of 30,000 population per acre.

During the present season numerous putrescibility tests of the effluent have shown it to be absolutely stable at all times and extremely low in turbidity. The excellent quality of the final effluent is attributed to the good quality of the tank effluent, and to the method of dosing the filter. The volume of effluent is usually four or five times the flow of the stream into which it discharges. At no time has there been any objectionable odor or any appearance of putrefaction in the stream. The stream bed is absolutely free from all indications of organic growths characteristic of sewage-polluted water.

It is the writer's opinion, judging from his observa-





THE PLANT CONSISTS OF A ONE-STORY SEPTIC TANK, DOSING CHAMBER AND SPRINKLING FILTER

tions of the working of municipal plants, that many plants in this country could be greatly benefited by the adoption of the short-cycle scheme of dosing. The practice, which is common, of constructing deep filters, and assuming the capacity to be in direct proportion to volume irrespective of the depth of the filtering material, is not consistent with the writer's experience. A filter of 4- or 5-ft. depth may be so designed and operated as to secure more perfect nitrification if operated at a rate of not to exceed 2,000,000 gal. per acre per day than can be obtained by the use of filters ranging in depth from 6 to 10 ft., as usually operated.

The sludge at Fort Myer is of unusually good quality, being thoroughly digested, as is evidenced by the fact that it dries rapidly. It is free from odor, does not attract flies, and is alkaline in reaction. All sludge has been disposed of by discharging it into shallow trenches excavated in the low ground near the plant. It dries quickly, notwithstanding the denseness of the soil and other unfavorable conditions.

During the period of maximum population the tank has a gross holding capacity of approximately 12 gal. per capita, and during the period of minimum population about 17 gal. per capita. The first compartment might be termed the "seeding" chamber, the second compartment the digestion chamber, and the third compartment digestion and sedimentation. Scum forms in a heavy mass in the first compartment, also of considerable depth in the second, and very lightly in the third. The action which takes place in the tank may be described as that of "division and transfer." The partially disintegrated matter in the first compartment is carried into the second compartment by the velocity resulting from the limited space between the scum and the sludge, and in the second compartment is again split up into a more finely divided condition. The finer particles are carried into the third compartment, where further division and sedimentation take place.

The effluent resulting from this action is in a better condition for oxidation in the sprinkling filter than that resulting from plain sedimentation, as nearly all of the matter carried in suspension is in a mineralized state. Analyses show that the nitrification is practically complete, and the effluent as it leaves the filter contains an unusually high percentage of dissolved oxygen.

Although complete data have not yet been received from many of the later plants of this type, it is anticipated that equally good results will be obtained as soon as sufficient time has elapsed for the tanks and filters to become thoroughly "ripened."

Keeping Track of Construction Plant at Hog Island

Condition of Every Piece of Equipment Known From Records Revised Daily—Precise Accounting System

By R. E. Roesler
Philadelphia, Penn.

MANAGERS and engineers building the Hog Island shipyards knew the character, condition and location of the hundreds of items of equipment employed as well as the good business man knows the contents of his desk. A highly systematized equipment department made this practicable. Summarized briefly, the duties of this department were: To know the exact location of each item at any time; to furnish information to various departments in various ways, concerning any equipment; to know what was idle and the reason for the idleness; to have on hand special, classified and full inventories; to pass on or void all orders to the purchasing department; to receive and identify all accessories and assign permanent numbers; to keep a record of work done by all equipment rented and contracted for; to anticipate future requirements, and to perform all clerical work required. No claim is made that the methods employed are the only possible methods, but the principle is sound and can be applied to almost any construction work.

Physical control is the manner of handling *physically* all equipment from its receipt until it becomes obsolete. Ordinarily, equipment is received at one point and can be passed through a single service station. This is the preferable arrangement, but at Hog Island it was impracticable, since there were several points of receipt.

An area approximately three miles long and one mile wide, about 900 acres, was covered by the yard. The three miles were along the river front and this front was divided into 50 shipbuilding ways and a wet basin. As the construction of the ways was assigned to five different contractors, five construction zones existed. The wet basin was considered a sixth zone, and the strip at the extreme rear of the island was made the seventh zone. Only the five construction zones are considered. Each of these was divided into five districts and these districts were designated by the letters A to Z.

A force of 35 men checked and reported receipt of all equipment. These were assigned as follows: One man in charge of each district, or 25 men in all; a zone foreman in charge of each five districts; three general foremen supervising the zone foremen and reporting to the supervisor of equipment, who reported to the superintendent of equipment. The total force was thus 35 men checking and reporting material.

When a piece was received the district man marked it, by brush and paint, with a temporary number, preceded by the letter of the district. On his list, under the assigned mark, he then recorded what the item was, whence it came, the number of the car or truck or the name of the boat which delivered it, the shop number, horsepower, size, etc. His lists, turned in to the zone foreman each night, were sent to the office and there checked up with the purchase orders, and the proper accounting records were made. The office assigned a permanent number in place of the temporary number and returned the lists to the district man, who substituted the permanent number for his original temporary mark.

Besides the force checking and recording receipt as described, there was a force of yard men, under the

storage yard man, who collected all available equipment, placed it in the storage yard, had it repaired if necessary, and thus kept the jobs clean of all idle equipment. These men increased the yard force to 75 men.

To control the activities of the yard forces, the office was divided into six departments:

1. The order department, which took care of all requisitions, purchase orders, expediting, and order and correlated files.
2. The receiving department, which looked after equipment received, identifications, special reports, permanent numbers and assignments.
3. The transfer department, which looked after all equipment in use, and kept a record of all transfers made, all available equipment reported and all reported for repairs.
4. The rental and contract department, which kept track of the receipt, identification, transfer, working records and return shipments of all equipment rented or contracted for.
5. The locomotive-crane department, which kept track of all locomotive cranes, recording work done, shut-downs, etc.
6. The inventory department, which made periodical statements.

In addition to these primary departments, there were an expediting and a car-record division and a filing department. The car-record division prepared the records for tabulating the information needed when cars arrived in the yard. By the work of the expediting division an effort was made to follow up the orders for equipment, from the time it was ordered until it was received, so that the status of any shipment could be known at any time. The duties of the filing department were to collect and deliver work and look after office equipment and supplies.

Clerks were assigned to the several departments according to their relative volumes of work. Each department force was headed by a "leader." The office was then divided into three divisions, with a chief clerk over each, to whom the leaders in his division looked for orders. The chief clerks reported to the superintendent of records, who in turn reported to the superintendent of equipment. When the work had been fully organized and the men had become trained, an office force of 80 men handled everything efficiently. This force added to the yard force of 75 men made an equipment organization of 155 men.

Accounting Separated Into Two Operations

Accounting consisted of two distinct tasks: (1) Accounting for equipment ordered, and (2) accounting for equipment received.

When equipment was ordered a requisition was issued by the stores department, after approval by the superintendent of equipment, on the purchasing department. One copy of this document was sent to the party initiating the order, one to the equipment department and one to the purchasing department. On receipt of its copy of the requisition, the equipment department made two copies for filing, one according to number and one according to classification. As soon as the purchasing department placed the order a copy of the purchase order was sent to the equipment department, which made six copies, one for each of the office divisions except the locomotive-crane division. Each division handled and filed its order according to its own particular needs; the procedure will be outlined very briefly.

In the order division, after checking the purchase order against requisitions, the order went to the numerical file clerk, who made out a sheet for each item and filed these sheets numerically; then to the ledger record clerk, and finally to the correlated file clerk, who entered the items on sheets which he filed according to classification. The receiving division received two copies of the purchase order and filed one according to classification of equipment and the other according to classification of shippers. The inventory department used its copy of the purchase order to check against equipment receipts.

Card Has Complete Record of Each Item

The work of the transfer department began by making up a transfer record card for each item shown on the purchase order. The transfer record card carried more or less complete information of each item, with additional columns for transfers to and from. These cards were filed according to the division of the yard—that is, by zones, districts, etc. A separate file was also kept for all equipment reported available or in repair shops, or obsolete. On receipt by the rental and contract department of its copies of these purchase orders they were separated and filed according to orders issued for contracts or orders for equipment rented or bought outright. Entries were also made on loose-leaf forms devised for the purpose of keeping each contractor's equipment separate. Entries were also made for equipment under contract and rented, on working records, giving a daily tally of the work done, the hours worked, the causes of shut-downs, etc. In this way a record was kept of performance, according to classification and according to contract.

No purchase orders went to the locomotive-crane department, as the work of this department consisted mostly of keeping records of crane performance. Requisitions for crane work went to this department, and cranes were assigned. A work-order card went with each crane assigned; on this card the engineman recorded his time, returning the card to the office when the work was finished. About 30 cranes were in use, and by this system a record was available, at any time, of the work done by any crane.

Methods of accounting on orders only nave been considered in the preceding description. On receipt of the equipment another set of accounting operations ensued. As previously described, the yard man turned in daily lists of equipment received. These receipts were registered on the equipment register and the lists were then checked against purchase orders. The original as returned to the yard, and a copy was sent to the record division, where proper notations were made on the various records. In turn the list went to the transfer and inventory departments, and, so far as equipment contracted for or rented was concerned, to the rental and contract departments, for the various records which they kept.

Chicago Water-Works Intake Crib Tilted Level With Screw Jacks

Lopsided Appearance of New Superstructure Corrected by Unique Engineering Operation—Instrumentman on Center Tower Controlled Moves by Means of Twenty-Four Leveling Targets

TILTED 18 in. out of level, the 1400-ton ashlar masonry ring forming the superstructure of Chicago's newest water-intake crib was recently blasted loose from its base, mounted on 300 jacks and restored to level partly by blocking up and partly by revolution. Using light charges of dynamite, a ring of concrete was removed from its place directly under the lower course of masonry. Only one stone in the entire 70-ft. ring was cracked. Expert house-movers operated the jacks, tilting the ring a fraction of an inch at a time, while an instrumentman checked each change of level and gave the foreman of the jacking crew the data by which he controlled the operations of his jack-men. Thirty days was the elapsed time from the start of operations to the finish of the underpinning. Scarcely a crack or an appreciably open joint was visible when the work was completed.

CONCRETE BLASTED OUT IN SECTIONS REPLACED BY SCREW JACKS

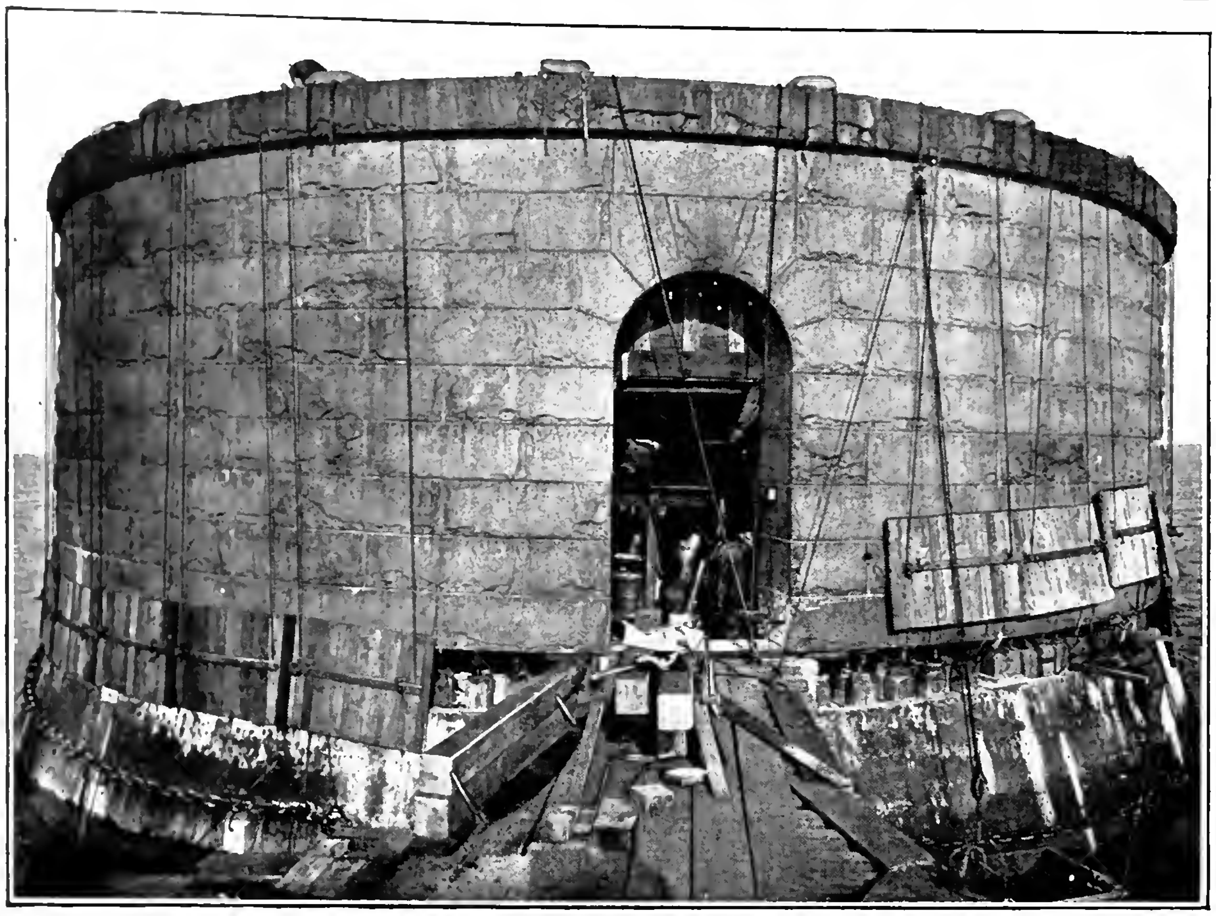
A—Inclined struts set on screw jacks prevented lateral movement of masonry ring. B—Bracing between inner and outer steel shells of caisson. Three rows of jacks set under masonry ring—concrete blasted out to cut ring loose.

Construction of the Wilson Ave. intake crib involved first the sinking of a caisson consisting of two concentric steel cylinders filled between with concrete, as described in *Engineering Record* of Jan. 23, 1915, p. 104. This caisson had an outside diameter of 70 ft. at the top and 90 ft. at the bottom. The inside diameter was 40 ft. On top of the caisson was erected a granite ashlar ring 70 ft. in outside diameter. Inside the caisson is the downtake shaft capped with screens and inside the granite walls is the housing for the crib tender and the appurtenances for crib operation.

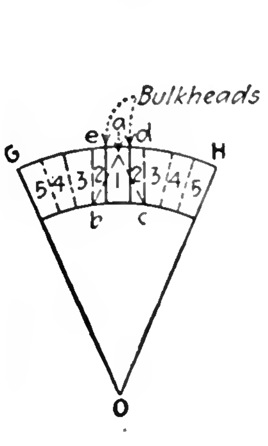
In the sinking of the caisson it tilted about 16 in. out of level, presumably because of varying density of the clay subsoil. This occasioned no concern, and after the inclined top was leveled up with concrete the masonry ring was built. Shaft sinking was then begun by the contractor inside the pumped-out caisson. This shaft was constructed by sinking cast-iron lining rings for a portion of its depth. Below this lining the usual wooden curbing was employed. The sides of the shaft swelled, and considerable more material was excavated than the volume of the shaft called for. When the shaft had been completed, it was discovered that the caisson had again tilted so that the top of the masonry ring was 18 in. out of level. It was decided to rectify the position of the masonry ring. Two methods of procedure were possible. One was to take down and reconstruct the ring after leveling up the caisson top with concrete; the other was to cut the masonry loose from its base, level it up and underpin it. The second procedure was adopted. It was also decided not to raise the low side the whole distance BE, as indicated by the sketch, but to revolve it on the axis YY so as to lower the high side from A to C and elevate the low edge from B to D.

To loosen the masonry from its concrete seat and to provide space for the jacks by which it was to be tilted level, a ring of concrete had to be cut out entirely around the crib. Blasting was the method adopted. As shown by the lettered view, this blasting had to be performed between the braces tying the inner and outer steel shells, and, of course, underneath the masonry ring, and it had to be performed so carefully that the masonry should not be cracked and the outer steel shell should not be broken through. The procedure was as indicated by the sketch. Between two sets of shell braces OG and OH, blasting under the ring was begun by drilling holes ba and ca and taking out a wedge cut. This cut was enlarged by removing wedges 2 and 2, and then three jacks were set and screwed up to a bearing. To protect the jacks, plank bulkheads were erected and cuts 3 and 3 were blasted, then cuts 4 and 4, and so on. These cuts were about 1 ft. wide, and as their removal made room, sets of three jacks were inserted. In this

manner the full circle of concrete was cut away and replaced with 300 jacks, as indicated particularly by the exterior view. Experiment determined the safe spacing for holes and the size of the charges. For each cut three 1¼-in. holes were drilled one above another. Each hole was charged with a half stick of 60% dynamite, and the three charges were fired by delay exploders. One jackhamer and one tripod steam drill did the drilling. A steam boiler and a locomotive air compressor furnished the power to operate the drills. After any portion of the ring had been cut through, protection of the men and the jacks from the wash of the waves was necessary. This was accomplished by plank shutters arranged as shown by the exterior view. When the shaft had been mounted on the jacks, preparations were made for the tilting operation. The interior bracing to prevent lateral shifting of the ring has been mentioned. A possible weak point in the ring was at the doorway. To guard against failure there the bottom of the opening was first spanned by a plank against which the jacks bore. Just above these planks, three anchors were set in the bottom course of blocks on each side of the door; these anchors were then connected across the opening by rods with turnbuckles. Finally, side posts were set on the anchors, and on these an arch center was erected and wedged tight. With this preparation, no weakness developed in the ring on account of the door.



MOVABLE SHUTTERS PROTECTED JACKS FROM WASH OF WAVES



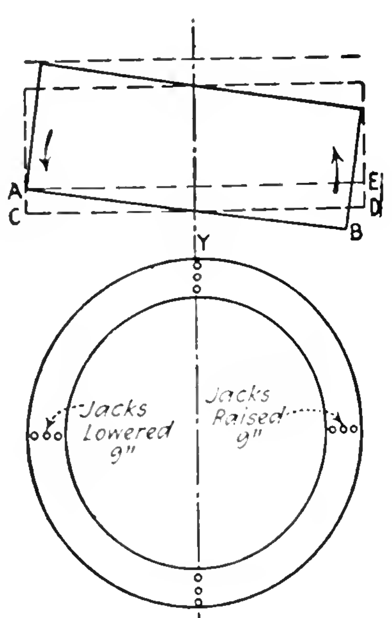


DIAGRAM SHOWING CRIB-LEVELING OPERATIONS

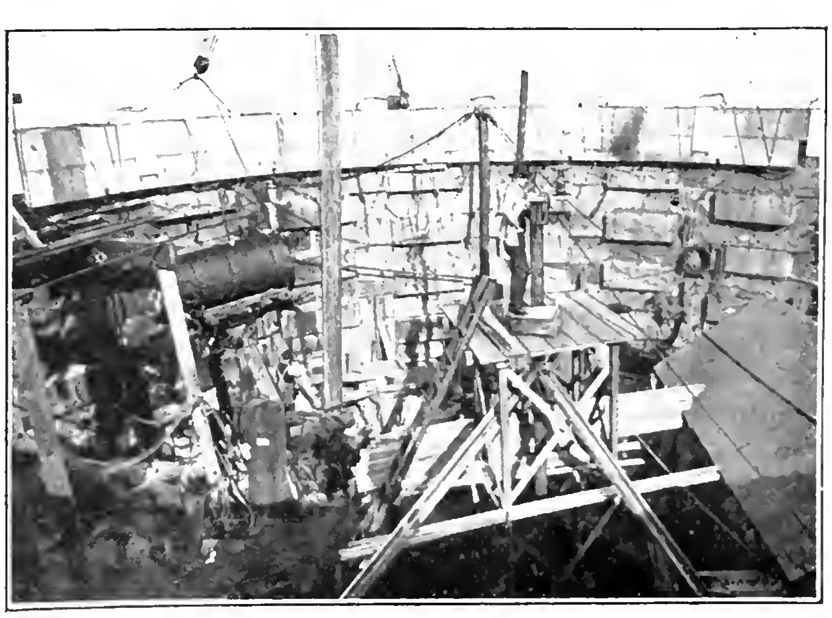
Preparation for instrument control of the jacking operations was made by erecting a pipe tower on the inner structure to carry the level, and building an observer's platform on independent supports. Around the inner edge of the masonary ring were set 24 targets at 15° intervals. On each target a top and bottom line marked the total change in elevation required at that point. These spaces were each divided into 100 equal parts. By this arrangement the instrumentman, swinging his telescope around, could check at sight the exact progress at each target. Down below, where the jack foreman stood, was a similar set of targets, so that as the observer called the figures above they could be noted below, and the foreman could speed up or slow down on any group of jacks, as conditions required. By this means no part of the jacking operations could get out of step more than a fractional part of an inch.

Twelve men operated the 300 jacks. These men were expert movers furnished by L. P. Friestedt Co. Referring to the sketch plan, it is seen that the jacks on the line of the neutral axis YY remained stationary, while those to the right were raised and those to the left were lowered in tilting the ring. The travel of the jacks varied from zero at the neutral axis to 9 in. at the points 90° from this axis.

When the ring had been jacked to level, brick underpinning masonry was substituted for the jacks, and the restoration was complete. The entire job took 30 days, and was carried out by city day labor under the direc-



INSTRUMENTMAN ON CENTER TOWER CONTROLLED JACKING BY SIGHTING ON RING OF TARGETS

tion of John Ericson, city engineer, and H. W. Claussen, assistant city engineer. Ernest Stromback was the engineer in local charge of the work.

LETTERS TO THE EDITOR

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

In Defence of the New Canadian Formula for Steel Columns

Sir—As a member of the committee responsible for the draft of a "General Specification for Steel Railway Bridges," published in the December *Journal* of the Engineering Institute of Canada, I desire to explain, in reply to Dr. Waddell's letter in *Engineering News-Record* of Jan. 16, p. 155, that the formula 12,000—0.3 $(l/r)^2$ was derived primarily from our interpretation of the published tests made by the Special Committee on Steel Columns and Struts, assuming 16,000 lb. per square inch (or one-half of the elastic limit) to be the proper unit-stress for tension members. If it should finally be decided to adopt a greater unit stress for tension members, the values in the column formula would be correspondingly increased; for it is, naturally, our aim to produce a specification which will result in structures of uniform strength, so far as practicable.

We obtained what we considered to be proper working values by taking the average of all the ultimate strengths of the solid columns for the several ratios of l/r, and dividing by 3, which figure is approximately the factor of safety on the ultimate strength of riveted tension members designed for a unit-stress of 16,000 lb. per square inch. These working values, as well as values derived from the formulas

$$12{,}000 / \left[1 + \frac{(l/r)^2}{36{,}000}\right] \text{ and } 12{,}000 - 0.3(l/r)^2$$

and 16,000 — 70 l/r, the latter used with a maximum of 14,000, are given in the table below:

l/r =	20	50	85	120	155
Working values	11,825	12,066	10,200	9,366	8,200
$12{,}000/\left(1+\left[\frac{(l/r)^2}{36000}\right]\right)$	11,900	11,230	10,000	9,580	7,200
$12{,}000-0.3\,(l/r)^2$	11,880	11,250	9,820	7,680	4,780
$16{,}000-70\,l/r$ .... (Max. 14,000)	14,000	12,500	10,850	7,600	5,150

In the above table, it will be noted that the Gordon formula,

$$12{,}000 / \left[1 + \frac{(l/r)^2}{36{,}000}\right]$$

agrees most closely with the working values derived from the Special Committee's tests, and may thus be considered as a safe guide in investigating the strength of existing structures; but the unit-stresses for ratios of l/r exceeding 85 are too high for practical reasons in new designs. Our parabolic formula 12,000 — 0.3 $(l/r)^2$ agrees very closely with the working values up to l/r = 85, and gives safe values when greater ratios are used, even to the limit of 200; moreover, its use is no more troublesome than use of straight-line formulas.

We are strongly opposed to limiting the ratio l/r to 100, as this restriction is not only a needless extravagance, but encourages the use of flimsily designed columns of fictitious strength.

There is nothing either radical or unusual in our column formula; the parabolic curve was proposed many years ago in this connection by the late J. B. Johnson, and many prominent bridge engineers in the United States are in favor of a much lower limit for compression in short columns than the allowed unit-stress for tension members. In this connection, the very valuable paper by J. R. Worcester on "Safe Stresses in Steel Columns," and the able discussion thereon, are recommended for careful study (See "Transactions" of the American Society of Civil Engineers, Vol. LXI, p. 150). The maximum unit-stresses for columns therein advocated by Mr. Worcester and others are, Worcester, 12,000; Prichard, 13,000; Seaman, 13,200; Emmons, 12,500; Horton, 10,666.

The American Railway Engineering Association's column formula is 16,000 — 70 l/r, with a maximum of 14,000 lb. per square inch. In the Quebec Bridge specification, compression members of carbon steel are limited to 14,000 lb. per square inch in conjunction with unit-stresses of 18,000 lb. per square inch for riveted tension members, and 20,000 lb. per square inch for eyebars, both of carbon steel.

R. S. Foulds, in an interesting article entitled "Column Tests and Formulas," published in *Engineering News-Record* of Aug. 9, 1917, p. 260, points out that the average strength of full-sized members in tension is about 54,000 lb. per square inch, net area; and in compression about 36,000 lb. per square inch gross area; that the elastic limits average about 30,000 in tension, and about 21,000 lb. (reduced) in compression. He claims that the J. B. Johnson parabolic formula 36,000 — 0.7 $(l/r)^2$ for ultimate strength is the most rational of all practical formulas, and that it corresponds to the average end conditions of bridge columns. Assuming the unit-stress of 16,000 for tension members, and taking into consideration the relative elastic limits of full-sized members in tension and compression (30,000 and 21,000, respectively), Mr. Foulds demonstrates that a working formula for columns of equal strength to that of the tension members should be: 11,000 — 0.214 $(l/r)^2$; or he would work to two-thirds of the elastic limit in both cases, using 20,000 lb. per square inch on the net section in tension, and 14,000 — 0.272 $(l/r)^2$ on the gross section in compression.

Finally, the Special Committee on Steel Columns and Struts, whose opinion cannot be ignored, recommends in its final report a working stress of 12,000 lb. per square inch for columns up to a slenderness ratio of 80; and 8000 lb. per square inch for columns having a slenderness ratio of 120, with interpolated values between these two ratios. Our proposed formula conforms practically to these recommendations for values of 0 and 120, but differs in using a curved line to connect these points, rather than a bent one.

Dr. Waddell refers to his formula 16,000 — 60 l/r, in comparison with ours, from which he concludes that compression members generally have either been overstressed by 15 to 25% or that the adoption of our formula would result in a corresponding waste of material. But the American Railway Engineering Association's formula, the one in most general use in recent years, is

16,000 — 70 l/r, with a maximum of 14,000; and the greatest difference between this formula and ours is 2250 lb. for $l/r = 28.5$, or about 16 per cent., whereas there is no difference when $l/r = 100$.

Referring to the so-called inconsistency between the formula 16,000 — 200 l/b for the compression flanges of beams, and our formula for columns, it is well understood that the two cases are by no means analogous; for the web of a beam provides continuous lateral support, and the empirical formula limiting the compressive unit-stress is provided to prevent the use of unreasonably narrow flanges.

Replying to the editorial comment in the same issue of *Engineering News-Record*, I would suggest that the compression members of a bridge are not of necessity properly proportioned, or of equal strength to the tension members, simply because they have shown no signs of weakness. No indications of weakness should be expected in a column as long as the stresses therein are within the elastic limit of the metal; and, with our liberal allowances for impact and for reversal of stress, few compression members, if proportioned by any of the recognized formulas, are likely to be subject to stresses of greater intensity than one-half of the elastic limit.

We all desire uniform strength throughout in our structures; and, taking into consideration the probability of increased loads in the future, together with deterioration from corrosion, a factor of safety of 2 on the elastic limit does not seem excessive for bridges.

W. CHASE THOMSON,
Consulting Engineer.

New Birks Bldg., Montreal, Can.

An Appreciation of Roosevelt

Sir—I have been very glad to note the appreciation of Col. Theodore Roosevelt in your Jan. 9 issue. As one who had the honor of meeting him in a more or less casual but still continuous way for 40 years, I have naturally come to know something of his interest in invention and engineering. This dated back to the time when, as a Harvard undergraduate, and through my humble intervention, he made his first acquaintance with the marvels of the Edison phonograph and the Bell telephone, to the accompaniment of music furnished by an organ built by his uncle, Hilbourne Roosevelt, one of the great organ builders of his time and a master of sound and mechanics.

During one of the intervening years, I had the honor of getting Governor Roosevelt to open by wire our electrical exhibition in New York City and discuss once again topics in the forefront of engineering. Some years ago, I was member of a committee on behalf of the engineering societies to ask President Roosevelt to open our splendid engineering building in New York City. He did this by message but not in person because, unfortunately, owing to complications in Washington, he could not leave; and, as he said jokingly in an aside, he "really was too busy to go chasing all over the country opening buildings for Carnegie;" but the protest was almost apologetic, and he was very much in sympathy with us. He had just declined to open a Carnegie building in Pittsburgh.

At another time I had the privilege of being, as the editor of the *Electrical World*, one of the four technical journalists invited to sit in at the first conservation congress in Washington, to which you refer so admirably. The conservation movement, as I sized it up, had begun with Richard Watson Gilder and Robert Underwood Johnson, editors of the *Century Magazine*, but President Roosevelt was wholly caught up in the spirit and enthusiasm of the movement; and from that time to this a new realization has existed in America of the value of our natural resources and of what the engineer is doing. Our whole civilization is an engineering exhibit, but conservation remains abortive; and it is amazing that after these many years, since the historical conservation conference at the White House, Congress is still allowing the water-powers of the country, then emphasized so strongly, to linger in wasteful neglect.

As one who frequently differed from his policies and practices, but who found him ever sympathetic to all the larger ideas of life and an intense admirer of the genius of our great inventors and engineers, I trust I am not exceeding the bounds of propriety in adding this little tribute to the memory of one of our noblest Americans.

THOMAS COMMERFORD MARTIN,
Secretary, National Electric Light Association.

New York City.

The Durham Land Colony

Sir—The article in *Engineering News-Record* of Dec. 5, 1918, describing the land colony at Durham, Cal., treats of an interesting and valuable experiment in land colonization. There are, however, a few points to which additional attention should be directed.

First, the real estate "shark" and his commissions were *not* eliminated. This fact was not known to the general public at the time when the land was originally sold nor, probably, was it known to the Land Settlement Board. Since that time, however, the two men who engineered the deal got into a dispute over the division of profits. In the suit that followed it was disclosed that their admitted profits on their options were considerably larger than the usual real estate agent's commission on sales of that size.

Second, the article makes a comparison between the overhead expense of $5918, for the first year of the project, and an assumed cost of selling alone, under private development, of $75,000. No analysis of the latter estimate is possible, but it might be stated that the amount is much greater than the selling costs per acre on several private projects of a similar character. With regard to the former sum, a simple mental operation shows that it amounts to a little less than $500 per month. A study of the statement of the amount of work performed during that time would indicate that some over-enthusiastic adherents of the plan of colonization have fallen, perhaps unwittingly, into the old error of public-ownership bookkeeping, and have made no proper distribution of the salaries and other expenses of state officials who devoted part of their time to the project. There is much to be said in favor of the proposition that the taxpayers of the state as a whole should help support the project, since its success will benefit the state as a whole, but the taxpayers should be apprised that they are doing so.

These notes have been written not with the intention of belittling the importance of the Durham experiment,

which I consider a step in the right direction, but rather because too fulsome praise of many a good plan has, in the end, militated against its success. Basing my opinion on my own experience as engineer for several colonization projects in California, I would say that the lessons so far to be learned from the Durham experiment are as follows: (1) Colonists should be carefully selected, not taking any man who happens to have the money for the first payment on the land, but rather selecting them partly for financial resources and mainly for experience in farming, for industry, and for general ability, to the end that every colonist should have a reasonable chance of success; (2) they should not be turned out on raw land to sink or swim—usually the former—but should have done for them at least part of the work of establishing an improved farm; (3) they should have the advice of experts, particularly during the first few years after settling on the land. Private colonization companies throughout the West are becoming cognizant of these facts, and many of them are acting upon this knowledge. It takes large capital, however, to do these things, which is one point where the state has an undoubted advantage over the private concerns, in the lower interest rates and better credit generally.

Disregarding the bookkeeping "camouflage" already mentioned, there is no doubt that, with the large amount of free advertising and the free administrative services of the able men on the Land Settlement Board as well, this first state colony is being handled more cheaply than would be possible on a private project. It remains to be seen, however, whether the total cost per acre of taking the raw land in large holdings and delivering improved farms to the colonist will in general be any less on a state-administered than on a private project.

A. T. PARSONS.

420 Market St., San Francisco, Cal.

[Mr. Parsons' letter was submitted to Dr. Mead, whose reply follows.—EDITOR.]

Sir—The letter of A. T. Parsons, commenting on the article on the state land settlement at Durham, printed in *Engineering News-Record* of Dec. 5, 1918, p. 1014, concedes that it puts into actual practice what he regards as the three essentials of successful settlement. The further statement might have been made that by doing this Durham has done more to improve the methods and practices of private colonization enterprises than all the legislation of the past ten years. Example is proving a better educator than precept.

The criticism that the article makes a better financial showing for Government action than the facts justify, and that the taxpayer is footing a larger part of the bill than it stated, is evidently due to a lack of knowledge of one of the most important features of this legislation. This needs to be cleared up. Mr. Parsons suggests that the real explanation is errors in public-ownership bookkeeping, and that the taxpayers of the state are paying the difference between the sum stated in the article and the actual cost. This is not the case. The amount of administrative expenses to be charged against this undertaking *was not fixed by the Land Settlement Board, but by the accountants of the State Board of Control.* If the cost had been larger that board would have said so, and, if they had fixed it at ten times the sum, this extra cost would not have fallen on the taxpayers of the state but would have been paid by the settlers *because the law requires all expenses of every kind to be so paid.* It is a self-supporting enterprise in the full sense.

The Department of Public Accounting in its report of this board's operations gives the following services as having been rendered without cost to the Land Settlement Board:

The University of California, salary of Dr. Elwood Mead and the use of an office in Agriculture Hall, Berkeley; Division of Soil Technology, University of California, soil surveys; United States Bureau of Roads and Rural Engineering, preparation of plans for irrigation and drainage works; State Department of Engineering, preparation of settlers' house plans; Attorney General, legal services; Board of Control, installation of accounting procedure. (To these might be added the services of the members of the board who have no salaries.)

It will be observed that the first three of these free services are rendered by agencies paid by the state and Federal Governments to promote the success of agriculture and to advance rural civilization. If the educational value of the work done at Durham was equal to work which might have been done elsewhere, and which would have been done elsewhere at public expense, then the Board of Control was correct in not charging this particular enterprise with any part of the salaries. All of the traveling and living expenses of officials that worked there were charged against the settlement.

The chairman of the board performed his duties in addition to his university work. The time given to constructive planning there has taught the state what successful settlement requires, more effectively than by talking about principles in a classroom. The Division of Soil Technology is making a soil survey of California as a foundation for the scientific agriculture of the future. It is a work that ought to be done, but some of the soil maps already made are now gathering dust. The soil map made for Durham was put to immediate and practical use. The settlers know why the acreage price of land was varied. Some of them speak with a sort of awe of the fact that they can trace in their crops the lines of the soil map. In other words, the science of soils has got a grip on the people of that settlement that it ought to have on the whole country, but which it is too often slow of securing. The settlers were not charged with the cost of that soil map, because the maps are everywhere made at public expense.

The Bureau of Rural Engineering has for years been giving to anyone who asked free advice about irrigation and drainage, which sometimes was labor thrown away because the advice was not followed. Here they had the inspiring opportunity of preparing a plan that they know would be carried out.

The professor of sanitary engineering was able here to create a mosquito-abatement district and thus forestall any possible malarial troubles. Usually he is not called in until illness has made remedial measures unavoidable.

The help rendered by the State Department of Engineering was given during a season of the year when

it could be done by people paid annual salaries, without any interference with other duties. It is of course admitted that there might be times when such free services could not be rendered, but if that had been the case it would have been charged and the settlers would have paid it, not the taxpayer. The services rendered by other departments were valuable, but not costly, and are rendered to all other public agencies, so that the decision of the State Accounting Board that they should not be charged here was in accordance with the general practice of the state.

The important point is not that the Durham colony was established at a small expense, but that the most efficient use of agricultural leaders was made there. This is a fact of great significance. The United States now spends more than any other two nations of the world for education in agriculture and to promote rural progress. Valuable as are the services now rendered, no one can study rural conditions without believing that, if experts were more widely used to create right conditions, as they were used at Durham, far more valuable results would be obtained. At present their work is largely corrective and not creative. They help to reform evils after becoming serious, but they allow others to arise without hindrance. At Durham the opportunity to build a rural neighborhood as it ought to be built, and in doing this to show how clearly they understood the problems of rural life, was given to the experts. Such use of them is the best use, and is destined to grow. California has not only formulated a plan which gives to poor men broader opportunities to obtain a home than they had before, but it has introduced an idea into education that is destined to have large application in the future.

No legislation can eliminate the real estate "shark," but, as the article truly said, the "shark" was eliminated in this case in selling the land to settlers. They knew what they were getting and they paid no commissions.

With regard to the saving to settlers which resulted from absence of commissions on sales, the article was conservative. The investigations of the Rural Credits and Land Settlement Commission of California, made in 1915 and 1916, showed that commissions of colonization agencies range from 10 to 30%. The State Land Settlement Board sold to settlers $744,928 worth of land. At the lowest commission this would be nearly $75,000. The average would have been more than this.

ELWOOD MEAD,
Berkeley, Cal. Chairman, Land Settlement Board.

The New York Central Train Wreck

Sir—I presume readers of *Engineering News-Record* will be interested in the wreck on the New York Central near Batavia, N. Y., on Sunday morning, Jan. 12, as observed by a passenger on Train No. 11 which crashed into No. 17. I was engaged in the rescue work for two or three hours following the crash.

The rear coach of Train No. 17, which was telescoped, is described in the Associated Press dispatches as made of steel. This may be true, but I have serious doubts. If it was a steel car it was of old design, for the exterior resembled that of a wooden car of old-fashioned type. The wreckage at the end of this car smouldered considerably but did not burn with much vigor, indicating that there must have been wood in it; furthermore, the fireman who came down from Batavia on the engine which was to assist Train No. 17 told me that the car had a wooden frame. If the roof of the telescoped car in some way had become dislodged it is conceivable that it might have been telescoped by the car ahead, but this is more or less improbable. I was on both sides of the wreck and up and down the track on both sides, and did not notice the roof of the telescoped car lying about.

It seems to me that if the rear coach of Train No. 17 had been of modern steel construction, such as the coach which telescoped it, there would have been almost no loss of life, if any at all. Unquestionably, we would all probably have been shaken up more than we were, but the loss of life was due entirely to the telescoping. Practically the entire force of the shock of the collision was taken up in the telescoped car, for not a single truck left the tracks.

If my supposition as to the use of wood in the construction of the demolished coach is correct, I believe that something should be done to make it a high crime to permit the use of even steel-lined cars on these fast trains.

HARLAND BARTHOLOMEW,
Engineer, City Plan Commission.
St. Louis, Mo.

More Comment on Engineers' Salaries

Sir—I note with interest the following advertisement in your issue of Dec. 19:

"Wanted—Transitman on stadia topography and location of property lines in Southern mountains, to live in isolated district in camp. Long job for desirable man. Salary $90 per month with maintainance in camp. In answer state age, school experience, if married and date available. Only preferred applications will be answered. ————" I omit the name of the firm, for obvious reasons.

It is possible some young engineer more anxious for a job than for what it is worth may take it at that price, but to advertise for men competent to do the work outlined and offer only $90 per month is an insult to the engineering profession. Here in Minnesota common, unskilled labor is getting more than that.

I have on my table at this minute a daily paper commenting on the fact that boys of school age had skipped school and earned $50 per week. This last item was from Philadelphia. My vocabulary is inadequate for further comment.

D. C. WASHBURN.
Elk River, Minn.

Corrects Statement of Levelman's Pay

Sir—In your issue of Jan. 9, p. 106, appears a letter signed "E. N. Gineer," which reads in part: "This is in striking contrast to $35 a month received by a leveler on a line now owned by the Baltimore and Ohio R.R., with $15 added for board."

I wish to say that this is undoubtedly a misprint, as our standard salary for a levelman is $145 per month and expenses over and above $25 when away from headquarters.

R. REIMANN,
Assistant Engineer, Baltimore & Ohio Railroad.
Baltimore, Md.

HINTS FOR THE CONTRACTOR

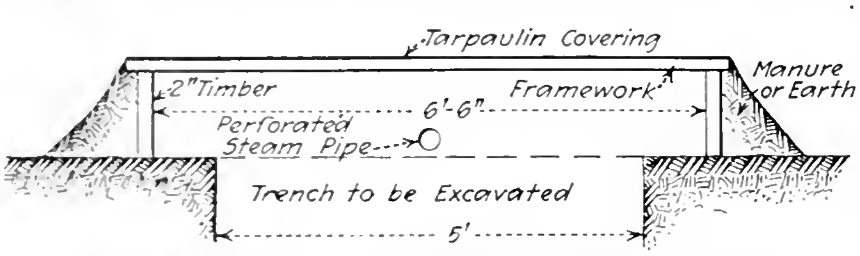
DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Steam Thawing Box Reduces Winter Cost of Trench Excavation

By L. McLaren Hunter

Engineer Main Drainage, Ottawa, Ont.

FOR thawing frozen ground over the line of trench where a large sewer was to be constructed, the method shown by the sketch was successfully used. Steam was supplied by the derrick boiler. The thawing



STEAM BOX FOR THAWING FROZEN GROUND

apparatus was placed in position in the morning for the next day's work, and the steam was kept on continuously for the 24 hours. When the box was lifted forward we were able to excavate with ease without the use of picks. This method brought the cost of the work down almost to the level of what it was in summer.

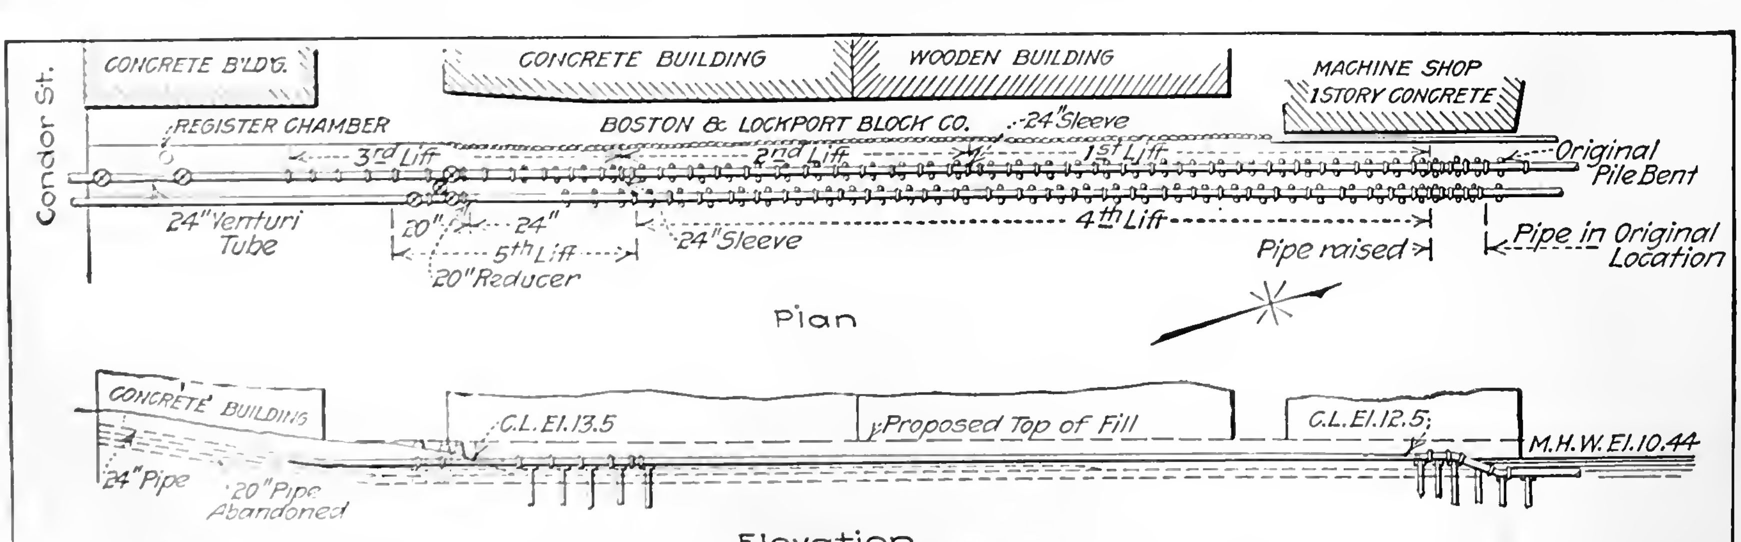
Raising Two Lines of 24-Inch Water Main Seven Feet

By Fred J. Sauer, Jr.

SCREW rods operating through timber cross-blocks supported on piles were recently used to lift to a new position two lines of 24-in. cast-iron water main at Boston. The work was done by the Boston & Lockport Block Co. in connection with an extension of its plant. Land was purchased from the City of Boston, subject to an easement for two 24-in. Class D water mains belonging partly to the City of Boston and partly to the Metropolitan Water District and connecting a tunnel under Chelsea Creek with the system supplying East Boston.

The pipes are 9 ft. c. to c. and enter the yard at an angle of about 10° with the horizontal and at an elevation considerably above high water. They originally continued at this angle for a distance of about 120 ft. From this point northerly the pipes were nearly horizontal at an elevation of from 4 to 6 ft. below mean high tide, the change in direction being made up in the joints. Approximately 700 ft. of pipe was partly exposed, being supported on piles at about the level of the flats. The remaining 250 ft. had been filled to a maximum cover of 14 ft. The grade of the Boston & Lockport Block Co.'s yard is about 11 ft. above the top of the pipes, so that in order to fill the newly acquired land to the existing grade without making the pipes inaccessible it was necessary to raise the pipes 7 feet.

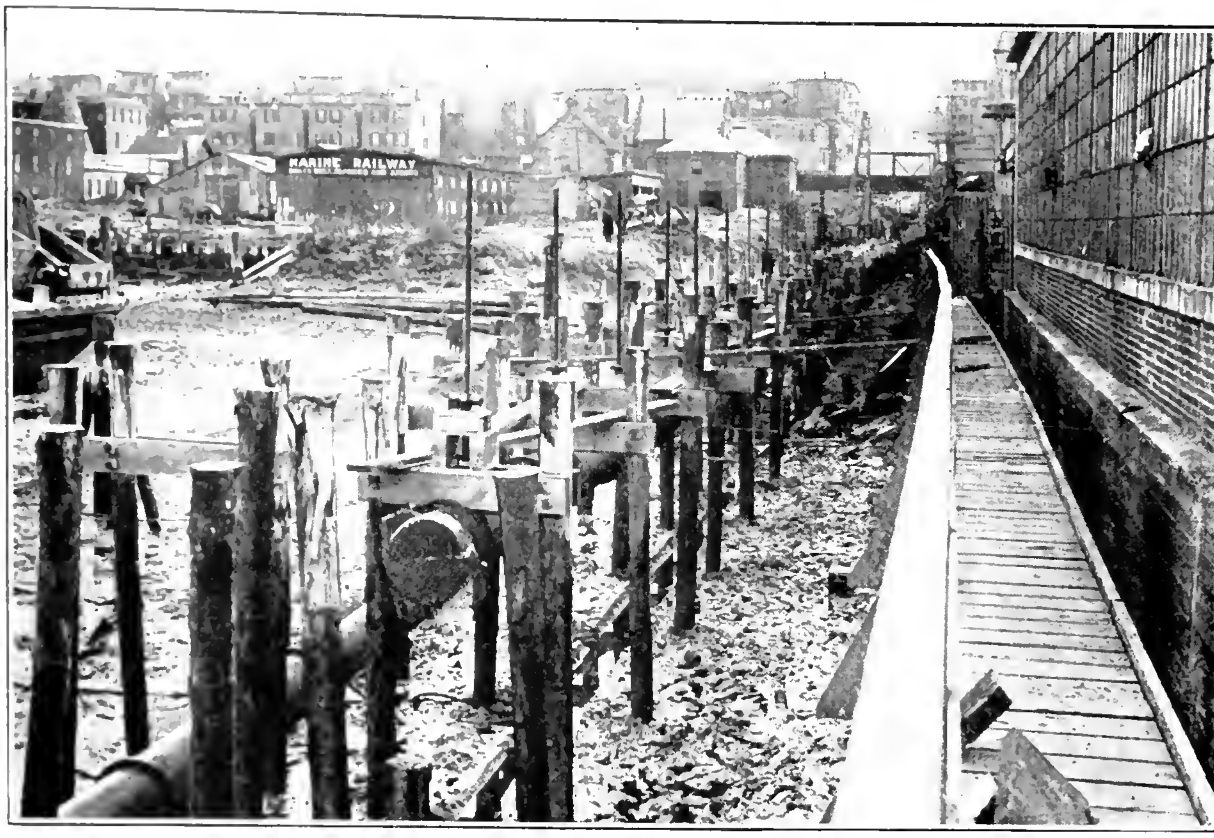
The piles and caps supporting the present pipe were in poor condition, having been exposed between the tides for nearly 50 years, and the soft mud in which the pipes were located made impracticable any system of raising from underneath. For the pipe that was exposed, or only covered to a depth of 3 to 4 ft., the method adopted consisted of driving 10-in. spruce piles on both sides of the pipe about 5 ft. c. to c. across the pipe and about 2 ft. behind each bell. The tops of the piles were left at least 10 ft. above the top of the pipe. The caps consisted of two 6 x 12-in. timbers, leaving a 6-in. tenon. These caps were used both to raise the pipe and as its final support and were designed to carry the weight of the earth fill and a heavy street load. For raising, the caps supported a 14 x 14-in. cast-iron bearing plate, through the center of which passed a screw which was raised by turning a threaded nut in a similar manner to the operation of a hand capstan. The screws were 2½ in. in diameter and lifted ½ in. for each complete revolution of the nut, the maximum lift without blocking being about 6½ ft. Wire-rope slings were used around the pipe. After the pipe



PLAN AND ELEVATION OF TWO LINES OF CAST-IRON WATER MAIN LIFTED TO HIGHER ELEVATION

The dotted lines on the elevation show the original level, and the full lines the level of the pipe as raised.

was raised to grade the caps were set under the pipe, and the piles were cut off at the top of the caps in their new position. The piles varied from 20 to 40 ft. in length, leaving from 10 to 30 ft. below the surface of the mud. No spur piles or bracing were used. The driving was done while the pipes were carrying water under 60 lb. pressure, the driving being done partly from a lighter and partly from a land machine. The lighter drew 30 in. of water and, as the pipes were only covered by from 4 to 6 ft. of water at mean high tide it was not possible to stay over the pipes for more than three hours each tide. The raising in fill was complicated by the local formation, a loose fill having been placed over the mud to a maximum depth of 14 ft., forming a very treacherous bank. The westerly pipe, which was 24 in. for its entire length, was not cut at the southerly end. The pipe was uncovered for a distance of about 24 ft. south of the point where it reached the proposed new grade, and as the pipe was raised the joints adjusted themselves to the new alignment, each joint being pulled out $\frac{1}{2}$ in. at the bottom. This straightening forced the whole section ahead 6 in., although the actual shortening of the line was only about 2 in. The raising was done in a manner similar to that described, except that no piles were driven, the bearing plates resting on long timbers that stretched across the trench to a firm bearing on either side.



ONE LINE OF PIPE HAS BEEN RAISED AND ONE IS IN ITS ORIGINAL POSITION

The easterly pipe, which at the southerly end reduces to a 20-in. line, was cut beyond the second gate. It was not considered economical to salvage the pipe beyond this point, as the city authorities were not willing to leave any of the pipe with the original cover. It was agreed that from this point to the street the easterly line should be replaced by a new pipe to be furnished and placed by the City of Boston.

At the southerly end were four gates. One of these was on a cross-over between the two mains, by means of which the flow of both lines was normally passed through a venturi meter. As it was necessary to maintain the flow through one line while the work was in progress, this gate had to be removed and reconnected after the lines had been raised.

The pipe was raised in five sections, the longest being 330 ft. It was found possible, with one man at each screw and one screw to each length of pipe, to raise at a rate of 1 ft. per hour, after the mud suction had been eliminated. With one screw for two lengths of pipe, it was necessary to provide three men at each screw, and the pipe was not so easily kept in good alignment.

The outer connections were made up of two $\frac{1}{16}$ bends and 15 ft. of straight pipe. On account of the difficulty of working in the soft mud, they were placed from a lighter, a connection being made up on the deck and hoisted into place as a unit.

The work was done in a period of 10 weeks, most of the delay being on account of the difficulty of obtaining labor. In using the figures on cost it must be borne in mind that labor conditions were acute owing to war demands as well as the influenza epidemic.

The cost of the work, excluding engineering, was about $8000, or $8.50 per linear ft., distributed approximately as shown in the following table:

	Quantity (Approximate)	Cost per Foot of Pipe Raised	Cost per Unit	Total Cost
Excavation	500 cu.yd. (200 cu.yd. wet)	$1.06	$2.00 cu.yd.	$1,000
Piles furnished and driven	142 piles, 4,700 lin.ft.	2.48	$0.50 lin.ft.	2,350
Lumber and hardware		.84	Y. P. 6x12 in. $80 per M. Hardware 7c. per lb.	800
Pipe connections		.74	Pipe specials 7c. per lb. lead 10c.	700
Gate chambers	4	.37	$87.50 ea.	350
Carpentry	144 sets of caps	1.06	6.95 per set	1,000
Backfill	500 cu.yd.	.32	.60 cu.yd.	300
All other work, including raising, setting, slings, and screws, etc., for 950 lin.ft. pipe		1.58	....	1,500

William Jackson, formerly city engineer of Boston and engineer for the Boston Water Board, in his report for 1886 describes the raising of 1870 lin.ft. of 48-in. main, the maximum distance raised being 18 ft. No costs are given. In *Engineering Record* of June 20, 1903, John L. Howard, division engineer of the Metropolitan Water-Works, describes a similar job of raising 36-in. mains, in which the cost is given as $11.03 per foot.

The piledriving and capping were done by the Aberthaw Construction Co. The jointing and connecting were done by the maintenance division of the Metropolitan Water Department, under the direction of S. E. Killam. The work was subject to the approval of the Metropolitan Water Board and the City of Boston, and was under the immediate supervision of the writer, who was advised by C. W. Sherman, of Metcalf & Eddy, consulting engineers, Boston.

NEWS OF THE WEEK

New York, January 30, 1919

Bills For Employment on Public Works

Two Measures Introduced in Congress to Promote Municipal and Governmental Projects

Two bills looking to the appropriation of money for public works construction of all kinds are now before Congress. One of them, introduced by Senator Kenyon of Iowa, was briefly described in last week's issue of *Engineering News-Record*. The other was introduced by Representative Kelly of Pennsylvania and provides for the creation of a United States Construction Service.

Under the Kenyon bill there would be established a United States Emergency Public Works Board, consisting of the Chief of Engineers of the United States Army, an officer of the Department of the Interior, an officer of the Treasury, and two citizens to be appointed by the President. The board would have direct supervision over all public works of the Federal Government in the present emergency, and for those works $100,000,000 would be provided. All agencies of the Federal Government would have to report to the board, within 30 days after the passage of the act, the construction plans they are contemplating.

In addition, the act would authorize the War Finance Corporation, for a period of one year, to make loans to the various states in order that emergency public works might be undertaken. Loans might be made by the War Finance Corporation for the work of counties and municipalities, but the Federal Government's relations would be with the state and the state would have to arrange for the advancement of the money to its local subdivisions.

In every case, whether for Federal Government or other public works, expenditures may be made only after there has been filed with the board a certificate of the Secretary of Labor stating that extraordinary unemployment exists in the particular community or vicinity in which the proposed works are located. The inspection of the work done with funds advanced by the War Finance Corporation would be made by officers of the Corps of Engineers.

Representative Kelly's bill would authorize the appointment of a National Emergency Board for Soldier Employment, consisting of the Secretaries of Labor, Agriculture and the Interior. This board would undertake the organization of a body of workers to be

(*Concluded on p.* 258)

Will Devastated France Be Rebuilt?

Credit Conditions and Other Economic Factors Will Greatly Retard Work and Be a Barrier to Aid From America

Readers of this article will find a detailed summary of the destruction in France, and of the reconstruction plans, on page 218 *of this issue.*—EDITOR.

"Why should we rebuild the ruins?" is the question in the minds of industrial and financial leaders in France. A complete change in the manufacturing layout of the country, due to the shifting and the taking root elsewhere of the industries formerly in the devastated areas, the necessity for preserving, with the limited means available, the existing industries that have expanded under war-time demands, and the financial conditions that will make the forming of commercial credits a slow process after the Governmental credits disappear with the signing of peace—all tend to delay greatly the reconstruction process and make the offering of help from the United States, either industrial or engineering, a difficult problem. This is the burden of a message brought from France to the manufacturers, engineers and contractors of this country by Pierce C. Williams, commercial attaché of the American embassy in Paris. On the other hand, he says, the large iron and steel plants in the areas occupied by the Germans where only a minimum amount of fighting was done can be put on a working basis in a comparatively short time, and the German plants in the recovered territories of Alsace and Lorraine are immediately available, so that France herself will be able to produce an amount of steel products almost, if not quite, equal to the necessities of her industries.

The rebuilding of the totally destroyed sections, if considered at all, will be subject to a number of important factors. The destruction included a large portion of the French coal industry that will, of course, have to be revived, but it also comprises several hundred miles of totally deserted farmlands so badly torn up by shell fire that it probably will never again be cultivated, but will probably be given over to pine forests. This area was dotted with towns and villages, as well as with many populous cities, some of which were considered among the most important industrial centers of France. Their industries included mines, blast furnaces, steel, textile and chemical plants and electric-power stations. But with the precedent in mind, that areas devastated in former wars were never rebuilt, and considering the fact that the inhabitants of these cities, towns and farms, are either dead or widely scattered, it is thought probable that these regions may also remain as they are.

Restoration Slow and Difficult

The sugar industry was also located in this section, the sugar beet having been raised nowhere else in France, but the mills are totally destroyed, having been, among others, a special target of German destructiveness. The beets were raised on small farms, and the buyers from the mills went among the peasants and bought up their raw material in small lots. Should these people return, the mill owner will ask, "Why build a mill when there are no beets?" and the peasant will ask, "Why raise beets if there is no mill to take them?" And, as pointed out by Mr. Williams, the synchronizing of these two branches of this industry will be a slow and difficult process.

The rebuilding of the iron and steel plants in the totally destroyed area presents another phase of the matter, with further difficulties. In the first place, the coal mines, flooded and otherwise damaged, must be restored and, second, the mills will have to be built according to local ideas and customs, since that part of the world has its own

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

Division of Engineering, United States Employment Service, 29 South La Salle St., Chicago, Ill.

Professional and Special Section, United States Employment Service; George W. Kirchwey, state director, 16 East 42nd St., New York City.

ideas to which it will be necessary to conform.

Until the final retreat of the Germans certain of the coal mines lying well within the battle lines were kept in more or less continuous operation, but just before the departure of the enemy he destroyed the hoisting apparatus and power plants and blasted out the concrete lining of the shafts as far down as possible. The top soil in this part of France consists of sandy silt very similar to the "muck" familiar to many of the tunnel builders and miners of our own country. This was held in place by concrete shaft-lining. The destruction of this not only flooded the mines with surface water, but precipitated down the shaft an avalanche of water-soaked sand and silt, together with the wreckage of the head works, thus making it impossible even to estimate the amount of damage that has been done. One representative mine in the Vimy Ridge battle ground, the location of which is now indicated only by a heap of bricks, twisted pipe and bits of machinery, was worked in five levels and had a shaft 1500 ft. deep. The owners told Mr. Williams that the water now stood within 50 ft. of the surface, and that they were unable even to predict when coal could be mined in paying quantity. Before that is possible, or even before coal-extracting machinery can be purchased, the owners point out, the coal mines must be entirely cleared of water. This, they say, will take from one to two years. The French officials and engineers responsible for organizing the work of "reconstituting" the coal mines are now assembling pumps, hoists, gas engines, and electric motors, etc., in order to begin the work as soon as possible. But not until this is well under way will there be any means of predicting when coal can once more be produced in large enough quantities to make feasible the rebuilding of the iron and steel plants, or even the mining villages and surface works. Since, as pointed out by Mr. Williams, the industrial plants depend on this supply of coal, there being no hydraulic or electric power available as a substitute in that part of France, delay is inevitable.

Outside Aid May Not Be Needed

On the other hand, outside assistance may not be needed to any great extent, because the French did not develop their iron and steel industries as completely as possible, preferring to export large amounts of the raw ore to Belgium and Germany, and they will probably export again. Furthermore, the iron and steel works in eastern France suffered only from pillaging. The steel and iron men told Mr. Williams that the warning sent out by President Wilson against wholesale destruction in their retreat was undoubtedly heeded by the Germans, and such operations were definitely checked. Of all of the iron mines only three were damaged to any

(Concluded on page 258)

Urge Passage of Bill for Hudson River Vehicular Tunnel

The Merchants' Association of New York City has asked Governor Smith to support the project for a vehicular tunnel under the Hudson River, between New York City and New Jersey, which provides that the estimated cost of $6,000,000 shall be paid equally by the States of New York and New Jersey. Bills for this purpose are now before the two state legislatures, since Congress has virtually refused Federal financial support. The association's letter to the Governor urges that an appropriation of $1,000,000 be made for immediate use.

"Careful consideration was given by our committee to the possibility that such a tunnel might have the effect of diverting to New Jersey industries which would otherwise locate or continue their location in New York. We do not believe that this would be the result, but, on the contrary, think that the benefits would be mutually reciprocal," the letter says. It states that there is a strong tendency at present to divert business from the port of New York to points where the port charges are less and that it becomes important that economies should be effected wherever possible in port charges.

Large Road Appropriation Combined With Post Office Bill

An appropriation for $200,000,000 for roads has been added to the House Post Office appropriation bill by the United States Senate Committee on Post Offices and Post Roads. The original bill as it came from the House provided for an expenditure of $357,-782,000. The amended bill provides for $50,000,000 this year and $75,-000,000 each in 1920 and 1921.

State-Insured Highway Construction Contracts Suggested

Consideration of a system whereby a state may provide its own insurance for the completion of highway contracts is suggested by Edwin Duffey, state highway commissioner, in his annual report to the New York legislature. The plan, if adopted, would eliminate the present practice of requiring contractors to furnish bond through one of the many surety companies. It has been the custom of these companies to furnish certified checks guaranteeing the execution of the contract, and bonds for the performance of the work, and this has been done for inefficient contractors, with little if any capital. This has resulted in poor performance. The undesirableness of this procedure has been emphasized by the abnormal conditions due to the war and by the refusal of the surety companies to take over and complete the contracts promptly.

In reviewing the inconvenience and loss thus produced, the report states that large amounts have been paid to the bonding companies by contractors, and, through their contracts, by the state, since the highway system was begun. In this time the companies have lost little money, but now that an emergency has arisen, the responsibilities which were assumed when the premiums were paid are disclaimed on the grounds of abnormal conditions.

The state carries its own fire insurance on state buildings and its own compensation insurance. In concluding, the report says:

"It would seem that a plan could be evolved by which the state could insure its own contracts and thus receive the protection for which payment is made; and the attention of the legislature is directed to this subject for such consideration as it deems advisable."

American Society Will Discuss Railroad Situation

Francis Lee Stuart, lately chairman of the Budget Committee of Eastern Railroads, will address the New York meeting of the American Society of Civil Engineers Feb. 5 on the national railroad situation today and a suggested basis for legislation.

Proposed New Water Law for State of Idaho

A proposed new water law for the State of Idaho was the principal engineering subject discussed at the joint conference of the Idaho Society of Engineers, the Idaho Irrigation Congress, and other associations interested in the agricultural development of the state. The conference was held at Twin Falls, Idaho, Jan. 13-17. The draft of the text, written by a committee of the Irrigation Congress appointed for that purpose, is based on the laws of Oregon and Washington, and also on the present Idaho law. A bureau of water rights is proposed, consisting of three men appointed by the Governor for terms of nine years each, one member to be appointed each third year. The members would be paid not less than $4000 and not more than $7500 a year. The bureau would take over the duties of the present state engineer as regards the distribution of water and the approval of plans for irrigation-district work; also the duties of the State Land Board in connection with its Carey act irrigation project; it would also make adjudications of water rights, subject to confirmation by the court. It is felt that the last-named change would save much of the expense and delay incident to the court's procedure as now carried out.

The act provides for changes in the methods of selecting and paying water masters on the various streams of the state, which changes, it is thought, would materially increase the efficiency of these men. In the selection of members of the proposed new board, the intent of the act drafted is to secure men of experience in the control of water resources, and to see that at least one member of the bureau is an engineer of ten years' experience.

Bills Provide Employment on Public Works

(*Concluded from page* 256)

known as the United States Construction Service, which would act under the general supervision of the Director of Soldier Employment. Employment in such service would be entirely voluntary. The works that the United States Construction Service would undertake would be the reclamation and preparation of agricultural lands, the establishment of logging operations and sawmills, the development of coal lands, and the building of roads, waterways and general public improvements that would aid or advance the projects of land settlement, forestry or mineral development which would be undertaken. All agricultural lands would be leased to settlers, not sold. The act would carry an appropriation of $500,000,000, said money to be raised for the Treasury by means of an issue of certificates of indebtedness bearing 3% interest.

Workers joining the United States Construction Service might be those who have been in civilian occupations, as well as discharged soldiers and sailors.

Provision is made for coöperative contracts with the various states for land settlement, forestry and mineral developments, the Government's contribution in such cases not to exceed 75% of the total cost of the projects.

Interstate Commission Overrules Director General's Rates

The Interstate Commerce Commission Jan. 20 in a decision written by Clyde B. Aitchison, formerly a member of the Oregon State Railroad Commission, overruled the rate on lumber products in the Pacific Lumber Co. case against the Northwestern Pacific Railroad Co. and others. It decided that the present rates charged for the transportation of lumber and other forest products from Humboldt Bay points to destinations in defined territories east of Denver, Colo., are unreasonable in that they exceed the rates contemporaneously in effect for California coast group points to the same destinations. The defendant railroads named in the case include virtually all the great lines in the Federaly-controlled systems from coast to coast, and the order issued by the commission notifies them to cease before May 15, 1919, from publishing, demanding or collecting present lumber rates, as covered by the decision, and to file new rates in accordance with the terms of that decision.

The new Director General of Railroads, Walker D. Hines, on Jan. 21 issued a formal statement in which he acknowledged the right of the Interstate Commerce Commission to review any of the rates initiated by the Director General, and denies that the latter has thought of contesting the right of the commission to make such a review of rates. He said the Federal control act places the power of review specifically in the hands of the Interstate Commerce Commission, and that at no time since the Government took possession of the railroads has there been conflict in jurisdiction between the commission and the Director General.

Form National Highway Association

Delegates from 37 highway associations, each having a trail of over 500 miles, touching at least three states, met at Kansas City, Mo., last week, and formed a permanent organization to be known as "The Associated Highways of America." Representatives from every state in the Union, except Massachusetts, were present, and 48 different organizations applied for membership. Of these, 37 were found eligible.

Nashville Engineering Association Publishes Strong Appeal

In a full-page advertisement in the Sunday *Nashville Tennessean* the Engineering Association of Nashville, Tenn., on Jan. 18 made the following strong appeal, addressed as an open letter to the members of the sixty-first General Assembly of Tennessee:

"The Federal Government realizes that this period, immediately following the close of the war, is beset with grave dangers from the social and conomic unrest, resulting from the increasing surplus of labor. The Department of Labor has created a new division, with the object of stabilizing these conditions and hastening the return of normal peace-time prosperity.

"This division has made careful investigations, and has arrived at the conclusion that the one industry which will most quickly start the wheels of progress is the building industry. Secretary Baker, realizing that private enterprises could not be expected to advance when the Government enterprises are stopped, says:

" 'We strongly urge that all public improvements be advanced to absorb labor; we ask that you use all influence with the state, county and municipal authorities to this end. Preliminary steps should be taken, in order that necessary authority may be secured in time for operation upon the opening of the construction season.'

"The Engineering Association of Nashville has already started such a campaign, and has the vigorous indorsement of the Department of Labor, and it asks you, Mr. Legislator, to take immediate steps to have all contemplated state work, such as buildings, bridges and roads, ready to start when the season opens.

"Granting that the cost may be more than at a later period—though there is little justification for such a belief—is it not better to spend this extra cost and get needed improvements than for our entire citizenship to suffer immeasurably more on account of idleness?"

Devastated France

(*Continued from p.* 256)

extent, and they not irreparably. It is evident, then, that no great amount of assistance will be needed in this industry. These mines, as well as those in German Alsace-Lorraine, will be worked to capacity to take care of the demobilized soldiers and assure a supply of raw material as soon as possible.

The coal necessary for their immediate operation, as well as the operation of other industries throughout France, that cannot be supplied by their own mines, will be drawn from other countries.

As to supplying needed material throughout the rest of France, Mr. Williams states that it is necessary that everything that can possibly be manufactured in France should be turned over to the French factories. While there has been enormous destruction of industrial capacity in the north of France, there has been in many lines a counterbalancing expansion in the center and southwest of France, particularly among factories that could produce any sort of munitions of war. These factories will be unable to guarantee jobs to demobilized French soldiers unless they are assured of orders growing out of the restoration of the devastated region. It is the task of the new Ministry of Industrial Reconstruction to see that these factories are converted into plants for peace as soon as possible; therefore it is safe to assume, says Mr. Williams, that the factories will receive every opportunity to make reconstruction goods. So pressing is this need that machinery, in the partially destroyed and other parts of France, that would be ordinarily scrapped, with the buying of complete new plants, will be repaired as quickly as possible and put into commission.

Supplies Needed by France

Hence a call will be made for such supplies as France does not produce, including machinery packing, greases, leather belting, and other things needed to put machinery into commission as soon as possible. There will also be a demand for railway supplies and specialties, small tools, some farm implements and semi-steel products. As the new Ministry of Reconstruction takes hold and starts the various factories to work there will undoubtedly be an impetus in the demand, but Mr. Williams warns against assuming that when this demand arrives the big reconstruction era, the time to rush large supplies and solicit contracts for the work, has come.

He says, furthermore, that even if, on account of the record made by the American forces in France and the large amount of construction machinery already there, the French officials might let contracts in the United States, the American contractors would experience great difficulties in carrying out their contracts. Not the least of these difficulties, says Mr. Wil-

liams, will be the small French contractor, who will demand a share of the work and, when obtained, will do it, or wish to do it, in his own way and not the ways of the American contractor.

Credit, however, says Mr. Williams, is the predominating factor of the whole situation, and many of the bankers of this country and France state that it presents the most serious problem. After the signing of peace there will be no Government credit, and the formation of commercial credit will be a slow process. As has already been pointed out, the reconstruction period will be fully two years long, and probably more. It will be impossible for the French people to pay their debts until they can produce enough goods to sell. Take, as an example, a steel man who wishes to place an order for, say, $200,000 worth of machinery or equipment. It will be impossible for him to pay for this material until his steel works are bringing in a return. This will vary from two to two and a half years, and no business house in this country will be able to assume such long-time paper. It will be necessary, then, for this steel man to offer notes that will be guaranteed by the French Government, but such long-term notes will not conform to the rules of the Federal Reserve system in this country. One of the ways, then, that might be used to finance this trade would be the formation of a syndicate in this country which would take over these notes and issue bonds of their own, meanwhile holding the French notes. On the surface, this seems to be a simple process, but the bankers point out that the social unrest and Bolshevism now threatening all the countries of Europe, and the more attractive financial possibilities elsewhere in the world, will make American financiers very slow to take up such proposals.

Must Supplement French Efforts

Concluding, Mr. Williams says: "America's part in the reconstruction of devastated France therefore will be to supplement French efforts. It will be necessary for us to supply French factories with only such raw materials as are not produced in France, and we shall doubtless be called upon to fill in certain gaps which at present exist in French industries. There are, or will be, many kinds of equipment which the French manufacturer will probably find it more economical to have made elsewhere, since it will be difficult for him to make them in his own plants, which for more than four years have specialized in the production of something very different. If American manufacturers can demonstrate to the French industrialists the advantage of having certain machines or parts of machines made in the United States, while the French concentrate on things for which their industries are especially adapted, a business alliance permanently beneficial to both nations will result. It is highly necessary, then, for the people of the United States to have great patience in the situation in France. At present, the business is not there, and until it develops the American manufacturer, engineer, and contractor must gather the facts bearing on the French problem and concentrate on the creation of an effective export, selling, or construction organization, in anticipation of the call which France may ultimately make upon our coöperation."

Engineers Decorated with Distinguished Service Cross

MAJ. GEN. WILLIAM S. SIBERT
Director of Chemical Warfare Service

MAJ. GEN. S. M. FELTON
Director General of Military Railroads

Government Will Sell Large Amount of Equipment

Ten million dollars' worth of equipment owned by the United Spruce Production Corporation is to be sold. Sealed bids will be received by the sales board appointed by Brigadier General Brice P. Disque, commanding officer.

The equipment, which consists of everything from picks and shovels to complete railroads and mills, capable of producing stock from the huge tree in the forest, to the finished product ready for shipment to the airplane factory, is in excellent condition and much of it, because of the abrupt ending of the war, was never used.

The corporation believes this to be an opportune time for the sale, on account of the reconstruction and adjustment, during which many large projects will probably be put under way very soon. This will require a large amount of machinery and equipment such as is to be sold, and will enable its absorption with the least possible disturbance of the markets and to the best advantage to the Government and the trade.

The equipment has been stored at Vancouver, Wash., where it may be inspected by interested persons, upon proper certification by the board, in the Yeon Building at Portland, Ore. Bids will be received at the same address up to and including Feb. 15.

Highway Traffic Association To Discuss Truck Regulation

A conference on regulations covering the speed, weight and dimensions of motor trucks will be held under the auspices of the National Highway Traffic Association at the Automobile Club of America, 247 West 54th St., New York City, at 8 p.m., Jan. 31. The discussion will be opened by the members of the Committee on Motor-Truck Regulations, which is composed of prominent men from all parts of the country. It is requested that highway officials, engineers, manufacturers and owners of motor trucks present their views freely, and thus aid in the solution of a problem which vitally affects the development of highways and motor transportation.

Testing Materials Society Joins Engineering Council

The American Society for Testing Materials has accepted an invitation to become a member of the Engineering Council.

All necessary formalities having been completed, this society is now in full membership, and its representative is expected to take his place at the annual meeting of the Engineering Council Feb. 20.

The present member societies of the Engineering Council are now the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Society for Testing Materials and the United Engineering Society.

Russian Railway Corps Still in Siberia

Awaiting Military Guards and Necessary Labor to Make Possible Any Progress in Work

The Russian Railway Service Corps, organized in 1917 to rehabilitate the Russian railway from Vladivostok to Petrograd, met from the outset with obstacles which prevented any headway being made in the direction intended. Upon arrival at Vladivostok the members of the corps were not permitted to land, the Bolsheviki having taken possession of the city. Some of the members went to Nagasaki, where they remained until about three months ago, at which time they managed to get into Manchuria and Siberia. There are about 200 of the corps awaiting developments there. They have been denied military guards and the labor with which to carry on the work, two conditions which make going ahead impossible.

Capt. J. D. Rogers, who returned to this country last June, stated that on the docks at Vladivostok there were about 500,000 tons of material held for months awaiting transportation facilities. He said that from Vladivostok to Petrograd the roadway, bridges and tunnels were in comparatively good condition, and that American engineers could, without difficulty, bring the railroad to a good working basis in a short time for the whole 6000 miles of track.

The corps was developed under the direction of S. M. Felton, director of military railroads, and is in charge of Col. George Harrington Emerson, former general manager of the Great Northern R.R. In an interview with the Washington representative of *Engineering News-Record* Mr. Felton said that the corps had been the victim of difficult circumstances and had therefore been unable to accomplish anything substantial, and that the length of the stay of its members in Russia is problematical. They will probably remain indefinitely. All expense of maintaining the corps is assumed by the Russian Government.

Government Will Dispose of Surplus Lumber Stocks

The second conference of the Government bureaus which have surplus building material to dispose of was called Jan. 20 by Richard L. Humphrey, director of building materials of the War Industries Board. At this meeting it was announced that all building-material industries had signified their approval of the plan of procedure that was outlined at the conference on Jan. 8, which was noted in *Engineering News-Record* of Jan. 23, p. 205. At this second conference the main subject discussed was lumber.

The Government surplus lumber stock will be purchased by various lumber interests in various parts of the United States at market prices, less a reasonable amount to pay for handling. The contract which was made will apply to lumber at any given point in amounts of 2,000,000 ft. and more. The purchase is to be completed on or before Aug. 1, 1919, with a further option to purchase lumber, as offered to the Government, in amounts less than 2,000,000 ft. at any given point on or before May 1, 1919. The conference announced that the surplus stock probably will not exceed 150,000,000 feet.

Committee Appointed To Study Automatic Train Control

The creation of the Automatic Train Control Committee of the United States Railroad Administration was announced Jan. 14 by C. R. Gray, director of the Division of Operation, as follows:

C. A. Morse, chairman; W. P. Borland, C. E. Denney, H. S. Balliett, Henry Bartlett, J. H. Gumbes, R. W. Bell.

The committee will make a study of the automatic train-control devices now undergoing test upon various lines of railroad or available for test, and report recommendations for the installation and further practical test of devices made available for that purpose, which they may consider practicable and reasonably conforming to the purposes to be accomplished. Their conclusions upon the mechanical or economic features of such of the devices as they may find available for practical use are also to be reported.

Government of Manitoba Appoints Drainage Commission

The Manitoba Government has appointed a drainage commission to investigate the problems of reclaiming by drainage large areas of land. The commission consists of J. G. Sullivan, chairman, formerly chief engineer, Canadian Pacific Ry., Harry Grills, of Sanford, and John A. Thompson, of Winnipeg.

Cornell Engineering Schools May Merge

At a dinner for the engineer graduates of Cornell University held in New York Jan. 17 announcement was made by President Schurman of the university that a committee of the board of trustees was considering a proposal to merge the College of Civil Engineering and Sibley College, in which mechanical, marine and electrical engineering is now taught. The schme—which in all likelihood will go into effect within a year, or perhaps two—contemplates one college of engineering in which all branches of engineering will be taught. President Schurman, Dean Haskell of the College of Civil Engineering, and Dean Smith of Sibley College, all enthusiastically advocated the merger.

Over 425 Cornell engineers were in attendance, the program including remarks by returned Army and Navy officers.

Under-River Water Conduit Contract To Be Relet

The contract for duplicating the Jersey City water-supply conduits where they cross under the Hackensack and Passaic Rivers was declared defaulted by the authorities of the city in December. Slightly amended specifications were adopted by the City Commission on Jan. 23, and invitation for bids was ordered. Michael I. Fagen is director of the Department of Streets and Public Improvements.

Engineering Societies

Calendar

Annual Meetings

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

AMERICAN INSTITUTE OF MINING ENGINEERS; 29 West 39th St., New York City; Feb. 17-20, New York.

The North Carolina Society of Civil Engineers will hold its first annual meeting at Raleigh Feb. 8. A prominent place in the program will be given to a discussion of the social status of the engineer and to consideration of state legislation regarding the licensing of engineers. Affiliation with national societies will also be discussed. Among the papers to be presented are "Coöperation Among Engineers," by H. W. Keuffner; "The Social Status of the Engineer and How It May Be Improved," by Dr. W. C. Riddick; "Importance of Testing Materials for Construction," by Ira B. Mullis, and "Bridge Engineering and Its Future," by W. L. Craven.

The Engineers' Club of Philadelphia will hold a regular meeting Feb. 18. Maj. Nevil Monroe Hopkins, Technical Research Branch, Ordnance Department, U. S. A., previously of George Washington University, will present a paper, illustrated with lantern slides, on "The Spirit and Outlook for Research and Invention," with reference to Germany's methods of fostering research, in the past, as compared with those of this country. A special meeting of the club will be held Feb. 15, at which H. F. Moore, professor of experimental engineering, University of Illinois, will read a paper on "The Fatigue of Metals," illustrated with lantern slides and motion pictures. At the weekly luncheon Feb. 4 the club will be addressed by William S. Twining, director of the Department of City Transit, Philadelphia, on "Financing City Improvements."

The Topeka Engineers' Club held its first meeting Jan. 25. The officers of the club are: President, J. E. Williams, county engineer, Shawnee County; secretary, L. B. Smith, chief engineer, Topeka Bridge Co., and treasurer, H. S. Putney, president of the Road Supply and Metal Company.

The New Jersey State Association of County Engineers held its annual meet-at Trenton, Jan. 21. The state-aid specifications, the result of a year's study and research by members of the association, to be recommended to the State Highway Commission, were approved. The following officers were elected for the year: President, Garwood Ferguson, Passaic County; vice-president, Thomas J. Wasser, Hudson County; secretary, Alexander H. Nelson, Atlantic County, and treasurer, Alvin B. Fox, Middlesex County.

The Kansas Engineering Society will be addressed by Lieut. K. P. Cecil on "With the Artillery at the Front," and by Capt. L. R. Tillotson, on "With the Engineers in France," at the annual meeting to be held at Topeka Jan. 30-31, noted in these columns last week. Among the other subjects to be discussed are: "New Methods in Engineering Education," "Geological Engineering in Kansas," and "Some Highway Troubles, Their Cause and Cures," by S. E. Fitch, New York State Highway Department. Papers will also be read on concrete, brick and bitumen roads.

The Illinois Association of Members of the American Society of Civil Engineers Jan 20 elected the following officers: Maj. H. J. Burt, president, and Charles B. Burdick, vice-president. A brief discussion on the work of the development committee was entered into by the 25 members present. Edgar S. Nethercut is secretary-treasurer.

The North Dakota Society of Engineers will be addressed by W. B. Stevenson of Fargo on "The Relation of the Engineer to Reconstruction Work," at the annual meeting to be held at Valley City, Jan. 30-31, mentioned in these columns last week. On the first day of the meeting a report of the committee on legislation will be presented. Other committee reports include those on roads, bridges and drainage. On the second day of the meeting inspection trips will be made to the Valley City light plant and water-works and to the Northern Pacific high bridge. The papers to be presented before the meeting include the following: "Range Spotting by Aëroplane," by L. B. Dale; "Members of the Society in the War," by E. F. Chandler.

The Montreal Branch of the Engineering Institute of Canada will hold a meeting Feb. 6 at which the following papers will be read: "Some Problems in Ocean Transportation," by A. W. Robinson, and "Manufacture of Nitro-Benzol and Aniline Oils," by G. J. Caron.

The Engineers' and Architects' Association of Southern California held a meeting Jan. 31 at which Dr. Albert L. Shiels, superintendent of the Los Angeles schools, spoke on Bolshevism. At a second session of the meeting Leroy C. Bishop gave a talk on the use of the acousticon and the dictograph.

The Albany Society of Civil Engineers held a meeting Jan. 28, and was addressed by Dr. A. T. Lincoln, professor of chemistry, Rensselaer Polytechnic Institute, on "Service of Chemistry in the War," with particular reference to explosives and gas warfare.

The Oregon Society of Engineers will hold its annual meeting at Portland, Feb. 3.

The Chicago Chapter of the American Association of Engineers elected the following officers, at the recent annual meeting: President, Paul Augustinus; vice-presidents, A. M. Van Auken, William J. Strong, Robert W. Shelmire and L. O. Wolf; secretary, Walter M. De Berard, and treasurer, L. G. Reed.

The Detroit Engineering Society was addressed Jan. 24 by Lieut.-Col. G. M. Barnes, Ordnance Department, U. S. A., who spoke on "Long-Range Artillery in War." Colonel Barnes' paper included special reference to railway artillery and was illustrated with stereopticon views.

The Rochester Engineering Society will meet Jan. 31 and will be addressed by Virgil M. Palmer and F. A. Collins, Jr., who will speak on "Fatigue Study," with reference to the factory worker.

Personal Notes

JOHN H. GREGORY, consulting engineer, New York City, has been appointed professor of sanitary engineering, Johns Hopkins University, Baltimore, succeeding Capt. Grandville R. Jones, Sanitary Corps, U. S. A., who recently died in the service. Professor Gregory has been engaged in consulting engineering practice in New York City for several years, specializing in water-supply work. After his graduation from the Massachusetts Institute of Technology in 1895 he entered the service of the Metropolitan Water Board of Boston as office assistant, engaged in the design of the Wachusett aqueduct. Later, for several years he was associated with Allen Hazen on various water-supply projects. In 1902 he became division engineer for the Jersey City Water Supply Co. on the 50,000,000-gal. daily water supply, in charge of the construction of the conduit from Boonton to Jersey City. In 1903 he became principal assistant engineer for the Commission on Additional Water Supply for New York City. In 1910 he was appointed engineer for the Metropolitan Sewerage Commission of New York. Several years later he became associated with Rudolph Hering, under the firm name of Hering & Gregory, consulting engineers, New York City, which firm was dissolved in 1917.

Readers who are returning to civil life from military, naval or other Government service are strongly urged to send in items about themselves and about their friends who are in similar situation. Items should give former position, describe character of military or other service and state the civil work to which the engineer or contractor in question is going. In the case of those with service abroad, information regarding the activities of the units to which they were assigned is especially desired.

JOHN F. STEVENS, head of the American Railway Commission to Russia, is to become chief administrator of the Transsiberian Ry., from Porgranichana to Omsk, a distance of 3000 miles, with General Horvath as co-director, according to recent dispatches from Vladivostok concerning the allied control of the Transsiberian line.

E. LOGAN HILL, secretary of the United States Shipping Board Commission on Port and Harbor Facilities, resigned recently to become associated with Heyl & Patterson, Inc., contracting engineers, Pittsburgh. Previous to his appointment to the Shipping Board Mr. Hill was assistant general manager of the Erie R. R. He will be attached to the New York office of the company, and will specialize in freight-handling problems.

MAJ. EUGENE W. STERN, Engineers, U. S. A., who was superintendent of roads in Base Section 2, with headquarters at Bordeaux, American Expeditionary Forces, has returned to the United States and has been discharged from the Army. He is at his home in New York City, where he was formerly chief of the Bureau of Highways, Borough of Manhattan. In his military service, Major Stern had charge of the construction and maintenance of roads near Bordeaux, and in that capacity built 35 miles of new road, resurfaced 45 miles, and maintained 100 miles. This work involved the handling of something like 100,000 tons of road stone, part of which was

produced under Major Stern's supervision.

A. H. KROM, director of the Division of Engineering, United States Employment Service, Chicago, has returned to the American Association of Engineers as assistant secretary. Since the division was organized in July, more than 5000 engineers have been placed in positions.

LIEUT. COL. H. W. HODGE, Engineers, U. S. A., recently returned from overseas, has received his discharge from the service and has returned to his office in New York City.

W. WALKER, acting division engineer, Grand Trunk Ry., Eastern Lines, has been appointed division engineer, succeeding Maj. F. C. L. Bond, promoted to be chief engineer of the system, with headquarters at Montreal, as noted in *Engineering News-Record* of Dec. 26, p. 1202.

LIEUT. COL. SANFORD E. THOMPSON, Ordnance Department, U. S. A., who has been in charge of the Estimates and Requirements Division of the Ordnance Department in Washington, has been discharged from the Army and has returned to Boston to resume his consulting practice.

CAPT. E. E. HOWARD, Engineers, U. S. A., who was commissioned last October, has received his discharge from the service and returned to his work with the firm of Harrington, Howard & Ash, consulting engineers, Kansas City, Mo.

WARREN WORTHINGTON, general superintendent, in charge of engineering and erection, Donner Steel Co., Buffalo, N. Y., has resigned to become special engineer in charge of steel-mill construction and equipment for the American Steel Export Co., New York City.

CAPT. WARD S. ROBINSON, recently discharged from the Personnel Branch, Office of Procurement Section, Operations Division, General Staff, formerly with the Illinois State Civil Service Commission, has been made head of the Middle West zone of the Division of Engineering, United States Employment Service.

GEORGE W. OSGOOD has been appointed engineer of the Tacoma, Wash., Port Commission, of which Frank J. Walsh has been appointed consulting engineer, as noted in these columns last week.

H. N. RODENBAUGH has been appointed engineering assistant to the Regional Director, Southern Region, United States Railroad Administration.

CAPT. H. C. MCCORMACK, Engineers, U. S. A., has received his discharge from the service and returned to the Koppers Co., Pittsburgh.

M. O. LEIGHTON, consulting engineer, Washington, D. C., who has been chosen as chairman of the newly formed National Service Committee of the Engineering Council, mentioned last week, p. 206, has made a particular study of hydro-electric development in this country. He testified before the Congressional committee on the possible commercial development of navigable rivers and streams in forest preserves, indicating also to what extent canalization of navigable streams would result in improvements to navigation as well as in water-power possibilities. He has made a study of the application of water-power to many uses, including industry, central stations, and electrochemistry and especially to railroad electrification. Mr. Leighton was born in 1874 and was graduated from the Massachusetts Institute of Technology in 1896. He engaged chiefly in hydraulic work, and in 1906 was appointed chief hydrographer of the Geological Survey. He continued in this office until 1913, when he took up consulting work. He has been a member of a number of Government commissions to study waterways.

Chairman of National Service Committee

M. O. LEIGHTON

BRIG. GEN. AMOS A. FRIES, Engineers, U. S. A., who was in charge of the Chemical Warfare Service of the American Expeditionary Forces, has returned to the United States and is now assigned to duties in Washington, D. C.

F. E. BONNER, assistant engineer, Forest Service, Washington, D. C., has been appointed acting district engineer for the Forest Service at Denver, Colo.

MAJ. WILLIAM M. ACHESON, Engineers, U. S. A., who was superintendent of roads for the American Expeditionary Forces, has returned to the United States and, since his discharge from the Army, has returned to his home in Syracuse, N. Y. He was formerly division engineer of the New York State Highway Department, at Syracuse.

D. C. NEWMAN COLLINS, engineer and architect, until recently associated with the Emergency Fleet Corporation, has returned to his office at 14 John St., New York City.

ARTHUR BONIFACE, JACOB SIEBERT and WALTER H. FEDERLEIN have become associated under the firm name of the Boniface Construction Co., engineers and contractors, with office at 52 Vanderbilt Ave., New York City.

FRANK W. WARD, formerly of Ridgville, Penn., has become city engineer of Niles, Ohio, succeeding H. W. Turner, resigned.

OBITUARY

LT. COL. HOWARD L. BODWELL, D. S. O., C. M. G., Croix de Guerre, assistant director of light railways, Canadian Military Area, France, died at St. John, N. B., a few days after his arrival from France. He was a graduate of the Royal Military College, Kingston, and had been connected with railway engineering in western Canada. He had also served two years in China on railroad work. At the outbreak of the war he went overseas as second in command of the Canadian Battalion, and subsequently won the decorations noted above.

COL. ROBERT S. LOW, of the contracting firm of Bate & McMahon, Ottawa, Ont., died Jan. 16. He had been engaged in war construction work, including the construction of Valcartier Camp and Camp Borden, and was afterward engaged in reconstruction work at Halifax.

JONAS F. YOUNG, locating engineer, Lehigh & New England R.R., died recently in Buffalo. He was born in 1847, and was graduated from Rensselaer Polytechnic Institute, Troy, N. Y., in 1868, taking the degree of C. E. in 1872. His first railroad work was for the Buffalo, Rochester & Pittsburgh. He afterwards became associated with the Lehigh Valley R.R., for which he served as division engineer for several years. Later he became division engineer, Chicago, Milwaukee & St. Paul Ry., on double-track work in Iowa.

MORLEY L. SMITH, director of engineering of the Technical School, Toronto, died Jan. 18, at the age of 37. He was graduated from Toronto University in electrical engineering in 1912.

Bridge Builders Report 27 Per Cent of Capacity Taken

The records of the Bridge Builders' and Structural Society, as collected by its secretary, show that during December, 1918, 29% of the entire capacity of the bridge and structural shops of the country was contracted for. During the entire year 1918 the new business placed amounted to 56% of capacity.

New Light-Weight Shovel That Can Be Converted Into Crane

In order to meet the wider range of usefulness that, according to manufacturers, will be demanded of construction machinery, a light portable steam shovel has been produced. It may also be converted into a crane, with a working radius of 25 ft. and able to handle a ½-yard clamshell bucket, by adding an auxiliary shaft carrying two drums, and the substitution of a longer and lighter boom.

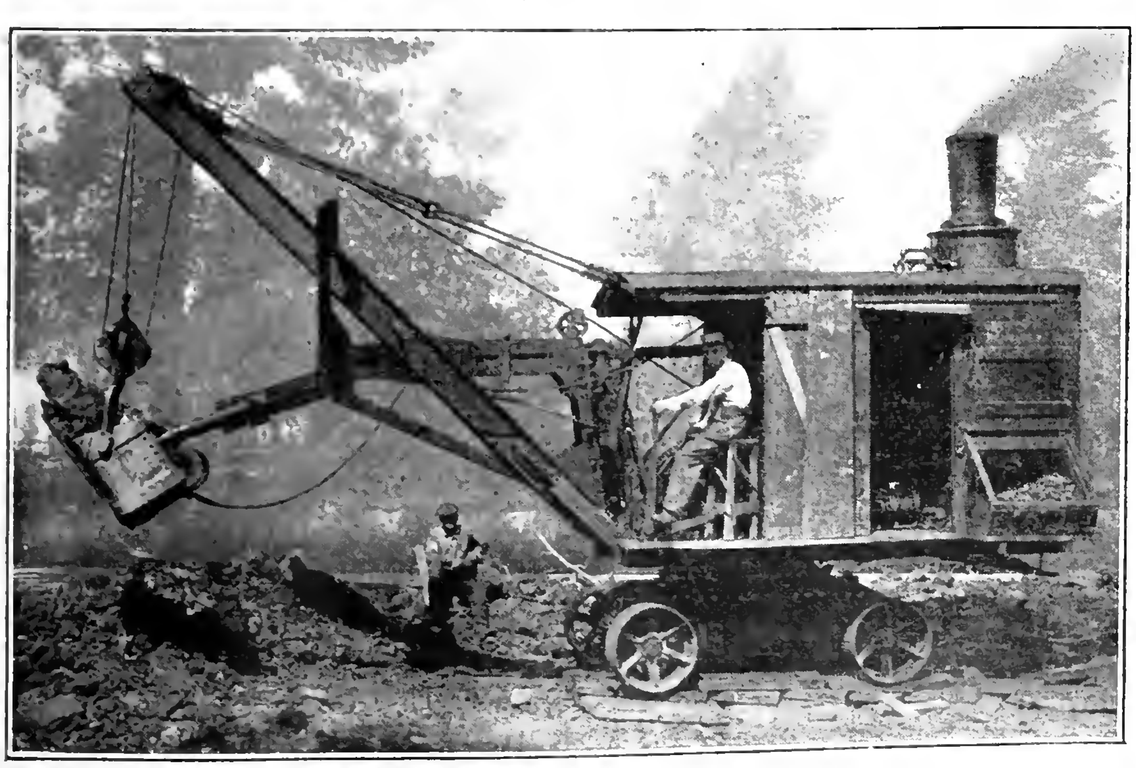
It is so designed that, with minor changes, it may be equipped for steam, electric or gasoline operation and the change from one form of power to another can readily be made in the field, at reasonable expense.

When equipped for electric or gasoline motor, this auxiliary shaft controls the dipper crowding motion, so that the only change from shovel to crane lies in the exchange of booms. All drums are power-driven, and the machine is adapted to clamshell or drag-scraper service.

Independent double reversing engines are employed for hoisting, crowding and swinging when the power is steam, and for electric and gasoline service a single motor is used, operating at constant speeds. The various motions are controlled through reversing frictions.

When equipped as a shovel the machine is regularly mounted upon a truck with wide-tired traction wheels, with both hand and power steer. It is self-propelling at speeds approximating 1½ miles per hour, and is designed primarily for the lighter classes of work to be undertaken by a shovel of this size. It weighs 14 tons and regularly uses a ½-yd. dipper. It has handled clay, earth or thoroughly blasted material at a rate of approximately 300 cu.yd. per day.

The shovel is manufactured by the Thew Automatic Shovel Co., Lorain, Ohio.



STEAM SHOVEL MAY BE FITTED GASOLINE OR ELECTRIC POWER

National Builders' Supply Association Elects Officers

At a convention held last week in Indianapolis, Ind., the National Builders' Association elected officers for the ensuing year. Arthur E. Bradshaw, of the Indianapolis Mortar and Fuel Co., was elected president; Charles M. Kelly, of Providence, R. I., vice-president, and John J. Voelkel, of New Orleans, La., treasurer. A board of directors to serve two years was also appointed.

Following the decision of the executive committee, the convention was conducted wholly as a business session, with discussions of questions of vital interest to the association. A resolution was passed and forwarded to Washington urging the Federal Government, through its proper departments, to make a speedy investigation, and an announcement, regarding the stability of the present market valuations, with the object of creating confidence in the industries represented by the association. The latter are being held back by statements regarding the possibility of an early decline in present valuations. These statements the members believe to be misleading.

Total 1918 Foreign Trade but Slightly Below That of 1917

Heavy December shipments brought the total exports for 1918 to $6,150,000,000, a decrease of but $83,000,000 from the 1917 total, according to an announcement by the Bureau of Foreign and Domestic Commerce. Imports for the year totaled $3,031,000,000. Imports for the previous year were $2,952,000,000.

Exports for December, the first full month after the signing of the armistice, reached a total of $566,000,000, a decided increase over the $522,000,000 recorded for November, although not up to the high mark of $600,000,000 for December, 1917.

Imports for December, however, at $211,000,000, were low as against $251,000,000 for November and $228,000,000 for the month of December of the previous year.

Business Notes

The Superior Portland Cement Co., Seattle, has purchased the plant of the Washington Portland Cement Co. at Concrete, Wash., adjoining the Superior plant. John C. Eden becomes president of both concerns.

Francis C. Bagby has succeeded J. F. Weiss as district manager for the Kansas City district of the Corrugated Bar Co., with offices at 1505 Waldheim Bldg. Mr. Bagby, who is a member of the American Society of Civil Engineers, was formerly manager of the St. Louis and Detroit offices of his company.

W. W. Cochrane, formerly in the purchasing department of the Chain Belt Co., Milwaukee, Wis., has been appointed manager of excavator sales by the Pawling & Harnischfeger Co., Milwaukee, Wis.

Trade Publications

"The Road to Peace" is the title of a recent 42-p. 11 x 14 book, in pamphlet form, showing in full-page half tones, pictures of war work in which the products of the Lakewood Engineering Co., Cleveland, Ohio, were used.

The McKenna Co., 1851 E. 38th St., Cleveland, Ohio, has issued Catalogue A, describing its bar-bending machines. It illustrates and describes five types of power bending machines, one hand bending machine, stirrup formers and steel shears, all of which are used in the handling of reinforced-concrete steel.

Drill sharpeners and stationary and portable air compressors of various types are the subject of four bulletins, 6 x 9 in., issued by the Sullivan Machinery Co., Chicago, as follows: Drill sharpeners, 24 pp.; simple straight-line compressor, 12 pp.; simple compressor with two-stage air cylinders, 12 pp.; small belt-driven compressors, 12 pp.; portable mine-car compressors and "rotator" hammer drills, eight pages.

Taking the Gamble Out of Garbage Disposal Contracts

BALTIMORE is not only to become the largest American city to have its garbage disposed of by feeding to hogs, but it has also made a step forward in taking the gamble out of garbage-disposal contracts. In the first place, the contract is for disposal only, thus eliminating the manifold collection risks. Then, and of great significance, the price which the contractor pays the city for the garbage is based on the selling price of live hogs in Chicago—and it is into live hogs that the contractor is to turn the garbage. This is a long step in advance.

No Engineer in Evidence

BUSINESS stands excused in large measure for subordinating the engineer, because of the engineer's own indifference to business affairs which affect his interests. Over 400 business men and public officials met last week in Chicago to combat a proposal by the Railroad Administration to increase freight rates on sand, gravel, crushed stone, and slag. This proposed increase in freight charges, as is pointed out on p. 306 and as was discussed editorially in *Engineering News-Record* of Jan. 30, p. 213, means a material curtailment of public work and an enormous additional burden of expense for work which must be carried through. State legislatures sent delegates to protest against the proposed action; public-works officials, commercial and industrial organizations an individual manufacturers came forward with statistics and argument to demonstrate that the action was unwise. There was not a speaker who represented the engineering profession, nor one who represented the contracting business.

Direct Locations for Trunk Highways

FEDERAL and state highway officials are already studying proper locations for through highway routes, and more of them will be doing so if the expected boom in highway building materializes. Heretofore it has been the custom to select a route with the idea of touching all the principal centers of population along the line, often at considerable increase in distance. With the increasing evidence that these routes will become parts of a connected freight-transportation system, it is a question whether one of the controlling economic factors will not be the shortest distance between the most important centers of population, as suggested by our correspondent on p. 299. No doubt, selection on this principle would, in the initial stages, cause a great amount of complaint from those not living on the main route, and from politicians who wished to use the roads as political capital to influence the voters in their districts. But such opposition subsides when the cities off the direct route realize the advantage of having the wear and congestion of through traffic removed from their streets. The State of Delaware has adopted this principle of location with excellent results, and with satisfaction to the public. We are on the eve of a tremendous development of the highways for freight transportation. Broad vision divorced from property and political interests will be necessary if these highways are to be located to the best advantage.

A Treaty to Develop the Port of New York

A TREATY between the States of New York and New Jersey is to be introduced in the legislatures of both states and, if adopted, will establish a "port authority" which will have jurisdiction over the entire port district at New York City included within the two states. The treaty has been framed by the New York-New Jersey Port and Harbor Development Commission, an interstate body created by the legislatures of the two states two years ago with authority to study the needs of the entire port and prepare plans for its further development. The commission has found what has been evident to many engineers and others who have studied the needs for transportation, sanitation and other necessities of this great center of population at the mouth of the Hudson, that the first essential for successfully treating these problems is that the needs of the district shall be considered as a whole without regard to the state boundary which bisects it. Few outside the engineering profession realize how frequently the development of great public works is hampered by the conflicting jurisdiction on different sides of state boundaries. But the Palisades Interstate Park Commission of New York and New Jersey has acquired and developed lands representing a value of some $9,000,000. If these two states can now establish a single authority for the entire port of New York, they will provide a further precedent of great value in encouraging similar joint state action by other commonwealths.

British National Aid To Highway Building

NATIONAL aid in road-building to the extent of £10,000,000 has been granted for 1919-20 through the Road Board to local authorities in England. This means the resumption of the help which was given annually for some years prior to the war. The action was

taken on account of "the desirability of stimulating employment on useful work at the present time," which is one of the leading arguments for an immediate increase in Federal-aid road work in the United States. Highway officials here who have watched their roads go to pieces under war-time trucking will find some comfort in the fact that the British national aid is to be used, so far as possible, on the important roads and bridges where heavy trucking is probable or has taken place during the war. This aid will not be granted to a local authority unless it agrees to carry on as extensive a road program as was finished in the year immediately preceding the war. The significant thing about this action, to American engineers, is the official recognition given in the first post-war road announcement to the fact that roads must be built for the traffic, and traffic should not be regulated to fit antiquated roads. Of course, it is ridiculous to allow one or two heavy vehicles to ruin a road fit for all other travel which uses it; but where motor trucks are useful it is sound economy to build roads for them and not force the people to pay needlessly high transportation charges, by severely restrictive traffic regulations. The war has brought motor trucking to the front, and with it the same sort of new problems which arose when motor cars came into use. The British authorities, conservative as they were in changing their road methods to fit the automobile, have shown no sign of conservatism in the new situation that faces them. But what are we doing?

Judgment and Calculation in Fixing Working Stresses

WORKING stresses for use in the design of engineering structures require to be fixed by means of technical judgment of remarkably high type. Many factors are involved, relating to present and future service as well as to quality of material; and few of them are amenable to calculation. It is therefore not possible to apply precise methods to the determination of these stress values; judgment must be the chief reliance in evaluating the factors of influence. Yet attempts are frequently made to fix working stresses by a process of calculation. Several such attempts are engaging attention just now, and it is of value to consider them, as an understanding of their nature will tend to prevent misconceptions of the meaning of their results.

Three different methods of calculation have come to light as having been used in arriving at allowable working loads on steel columns. Their results, curiously enough, are identical, though the starting points and the methods of procedure employed differed considerably.

According to the report of the American Society of Civil Engineers' Committee on Steel Columns and Struts, now discharged, the committee fixed the loading which it recommended as the limit of safety by comparison with tensile-stress practice. It considered that both in tension and in compression 50% of the elastic-failure load might be used as working load with safety, this view agreeing with ordinary practice as to tension members. The committee then reported that its tests showed the elastic limit (or "useful limit") of columns to be 24,000 lb. This value of 24,000 was reached by a unique process; it is the average value determined from a large number of tests, in turn averaged with the lowest single value of all those obtained. Evidently the committee believed that the figure of 24,000 lb. per square inch thus found represents a strength that may with reasonable certainty be counted on under all conditions. The manifold influences that separately affect column resistance were not considered in detail, but these effects were pooled in the committee's judgment as described, and the line of safety was, so to say, put at the edge of the middle third.

A different explanation of the 12,000-lb. column-load limitation has been given by an engineer of note who formerly belonged to the committee. His view is that 40,000 lb. may be accepted as the ultimate limit of tensile value, characterized by elastic failure of the steel; and that 30,000 lb. is to be taken as the limit of column strength, a value maintained with fair reliability throughout a large range of conditions. The same proportion of both, then, should be taken as safe working load. Since the commonly used tensile stress of 16,000 lb. is 40% of the tensile value, the limit of column load is to be fixed at 40% of 30,000, or 12,000 lb. per sq.in.

Rather higher factors of safety were adopted by a committee of Canadian engineers in devising a new column formula, embodied in recently published bridge specifications of the Engineering Institute of Canada. This committee determined one-third the average strengths of various groups of test columns, using the same tests studied by the American committee. This value of one-third was taken to be coördinate with a stress of one-third the ultimate strength for riveted tension members. Again the basal figure for column loading was found to be 12,000.

It is hardly possible to contemplate these different procedures, all yielding the same result, and feel any great confidence in the merit of the calculations. In fact, the conclusion cannot be escaped that the three calculations are nothing other than methods of judgment, whose thin veneer of figures has little meaning. Whatever virtue resides in the recommended working stresses, then, is due to the excellence of judgment of the men who offer them, and not to the excellence of the analysis presented.

The use of calculation in fixing stress limits, where the real decision is made by judgment, is harmless when the true state of affairs is appreciated. It may easily have a misleading effect, on the other hand, when the calculation is regarded as producing exact results.

There is a tendency, moreover, to regard working stresses, and, for that matter, specifications, as laying down boundary lines between safety and danger. This is apt to prove a particularly harmful view when working stresses backed apparently by mathematical deduction are expressly stated to be limits of safe loading. The fact is, of course, that no stress limits afford complete protection againt unsafe design; yet this truth is often forgotten when the question of working stresses is approached from the standpoint of safety. The controlling consideration with regard to all broad rules of design practice is the proper utilization of the material,

a matter demanding quite as much care to avoid waste of material as to avoid overstress. This is preëminently a field for the exercise of judgment, and the appearance of calculation applied to the subject tends to interfere with successful use of judgment rather than to promote it.

Are You Doing Your Share To Start Construction?

CALAMITY howlers are never popular. The world loves a cheerful optimist. But there are times when a considered pessimism is necessary, because it demands a looking forward and a seeking for remedies which never enter into the program of those who hold that everything is well in this best of all possible worlds. Today construction work is in so low a state as to demand an active pessimism that can be translated into the kind of results which optimism only passively hopes for.

Six months or a year ahead of us lies a period of unprecedented industrial activity. This must be so. A world starved for four years of everything but bare necessities must be fed, clothed and amused by producers made measurably fewer by the ravages of war. Plants and utilities and structures left for years to take care of themselves must be restored to an economical working basis. Normal increase in producing capacity must be regained. Construction, next to agriculture the basic industry, will absorb growing numbers of men and quantities of material and vitalize all industrial life.

Meanwhile, there is today a dearth of construction work. In spite of certain widely circulated reports of unprecedented activity in all kinds of building—reports based on a kind of whistling courage—every contractor and engineer knows that never before in the memory of the present generation has a February come with so little actual business in prospect or on the books. In consequence this reservoir to provide against unemployment and to restore confidence—for agriculture will not begin to absorb labor for some months—is empty and shows no signs of immediate filling. And soldiers and munition workers are coming back toward industry by the millions.

Why is construction holding off? Because it costs so much? No; because it is hoped that six months from now it will be cheaper. Because no man wants to spend $2 today for that which he expects to be able to buy for $1 tomorrow. Millions of dollars of work would start immediately if there were assurance that the cost of such work would be the same next year or even next summer. We are in a condition where individual timidity is outweighing mass confidence. Every prospective builder, be he the president or director of a railway, the mayor of a city or the owner of an industrial plant, is drawing into his own shell of self-protection and betting on his own personal preservation in the general cataclysm of panic which is bound to follow continued inactivity. Everyone is counting on not being the hindmost in the devil's drive which he hopes against his better judgment will not come.

One of the most misunderstood laws in the world is that of supply and demand. How often is it quoted as inevitable! How often is it forgotten that the essence of inevitability is time! Demand controls supply—but not immediately, and in the intervening days, or months, or years can happen all sorts of things that confuse the law and serve to destroy or impair its natural results. Everyone is sitting back and waiting for the obvious demand of the world's needs to adjust the elements of his part of its supply to his liking or to his expectancy.

What is going to be done about it? The necessity in the case of public works is obvious. In spite of costs or prices, it is the solemn duty of every public agency to start immediately all of the necessary construction activities which have been delayed for the past year or two. What if the cost is greater; charge it up to insurance. Unless economics and common sense and statistics are all equally wrong, we are fast approaching a period of unemployment with accompanying social distress far more expensive to the body politic than any possible increase in cost of construction due to present conditions. Let those bright optimists of the do-nothing type take what comfort they can from their self-satisfaction. The world is in ferment. He who runs may read.

The obligation is just as great on all of the private interests that go to make up a piece of finished construction. Personal selfishness must be forgotten now just as it was in the nineteen months of war. Every element—the owner, the contractor, the material man and the laborer—must be prepared to give up something. As it stands today, no one will concede anything. The material man wants his full price, labor wants its wartime wage, capital must be assured of its full investment profit.

Cannot a scientific method of preparing for the emergency be devised? Cannot an agreement be reached between the various parties to a construction operation whereby future adjustments in prices will be cared for? The fear of a lowering of prices after the work is started and paid for is holding up more construction than fear of the high prices themselves. Why cannot every new construction contract be written on a delivery basis? It would be merely a modification of the Construction Division's form of contract, by virtue of which the owner would pick a responsible contractor at a graduated but limited fee and then pay for his labor and material at the price they commanded when used. The contractor wants work to keep his organization intact; he should be willing to make some sacrifice in his normal profit. The material man must dispose of his stock if he expects to keep in business; cannot he contribute something in the way of reduced prices? Labor must live; may its contribution not be an efficient performance which all employers say will alone make possible the high wages demanded to meet increased living costs? The owner gets an approximation of full future value in the adjusted costs, and the difference is what he pays toward the common good.

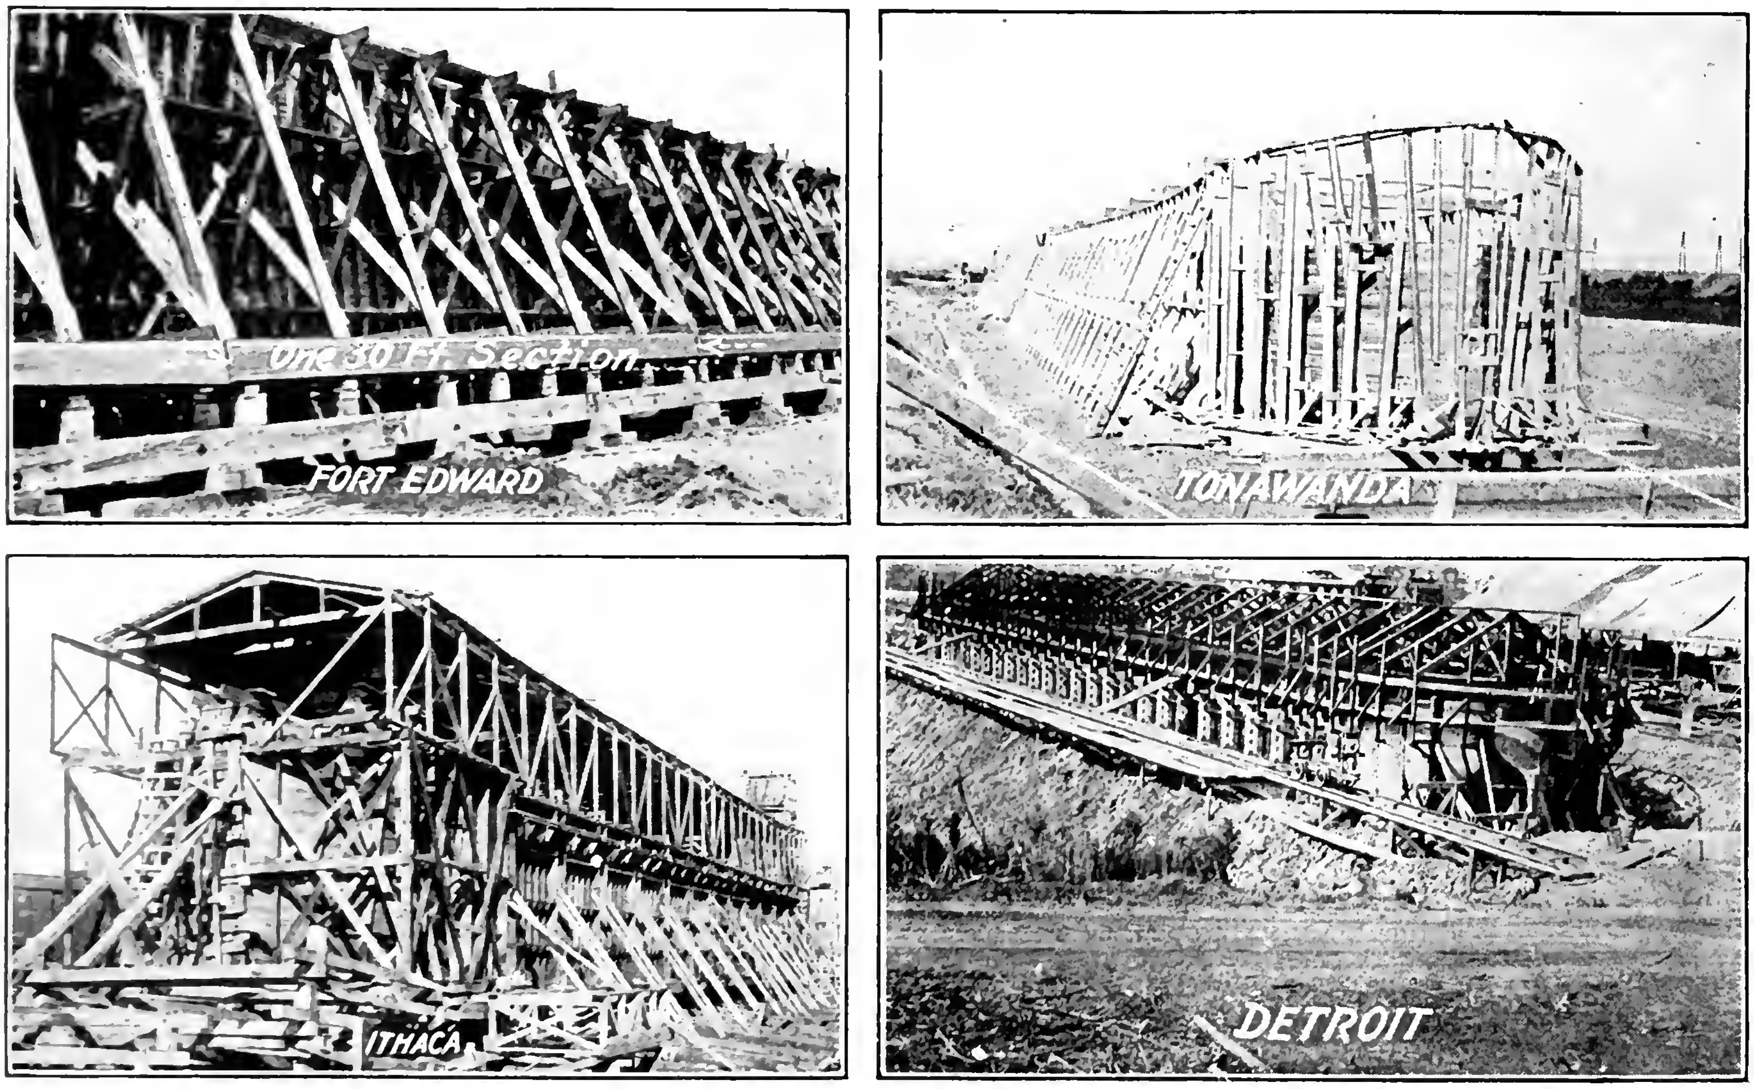
This is a time for coöperation based on a lively sense of impending common danger. Optimism for the future is justified to the extent that prompt present action is taken. Ahead of us lies a wonderful and growing prosperity. Must we pass through a slough of depression for lack of united action and individual sacrifice? Did patriotism go out of business on Nov. 11?

How the New York Canal Concrete Barge Is Being Built

In Four Yards Independently at Work on Same Type of Boat Differences May Be noted in Yard Layout, Launching Schemes, Form Construction and Steel Placing

EXCEPTIONAL opportunity to study methods of concrete-boat construction is afforded by the simultaneous building in four different yards of the 500-ton barge designed by the Emergency Fleet Corporation for the Railroad Administration, and to be used on the New York State Barge Canal. While the general operation in building these barges is supervised by the engineers of the Concrete Ship Section of the Fleet Corporation a free hand in plant layout and construction details is allowed the contractor. It happens that site conditions and individual initiative are so various in the four locations that many contrasting solutions of problems that are essentially the same are available.

The design of the New York State canal barge was described in *Engineering News-Record* of Aug. 8, 1918, p. 271. The boat is 150 ft. long, of 21-ft. beam, and 12 ft. deep. It is of the simplest open-box type, with frames 5 ft. on centers, a 3-in. shell, cantilevered side decks and an open hatchway crossed with deck beams every 15 ft. The bottom is flat except for a 2-ft. quadrant curve at the bilge. Contracts were let for 21 of these barges last summer, it being provided in the advertisement for bids that the barges be built at such locations that they could be towed to the New York canal system. Accordingly, the contracts were let to the Holler-Davis-Flood Co., for eight to be built at Fort Edward, N. Y., which is on the Hudson River some 60 miles north of Albany; to the Caldwell-Marshall Co., for four to be built alongside of the Ellicott Creek canal at Tonawanda, N. Y.; to the Cummings Structural Concrete Co., for four to be built on the inlet which makes in from the south end of Cayuga Lake at Ithaca, N. Y., and to Thomas E. Currie (the Grayhaven Shipbuilding Co.), for five to be built on the Detroit River, Detroit, Mich. Several boats have been completed at each of these yards, and all will be delivered to the Railroad Administration in time for the opening of navigation on the canal next spring.

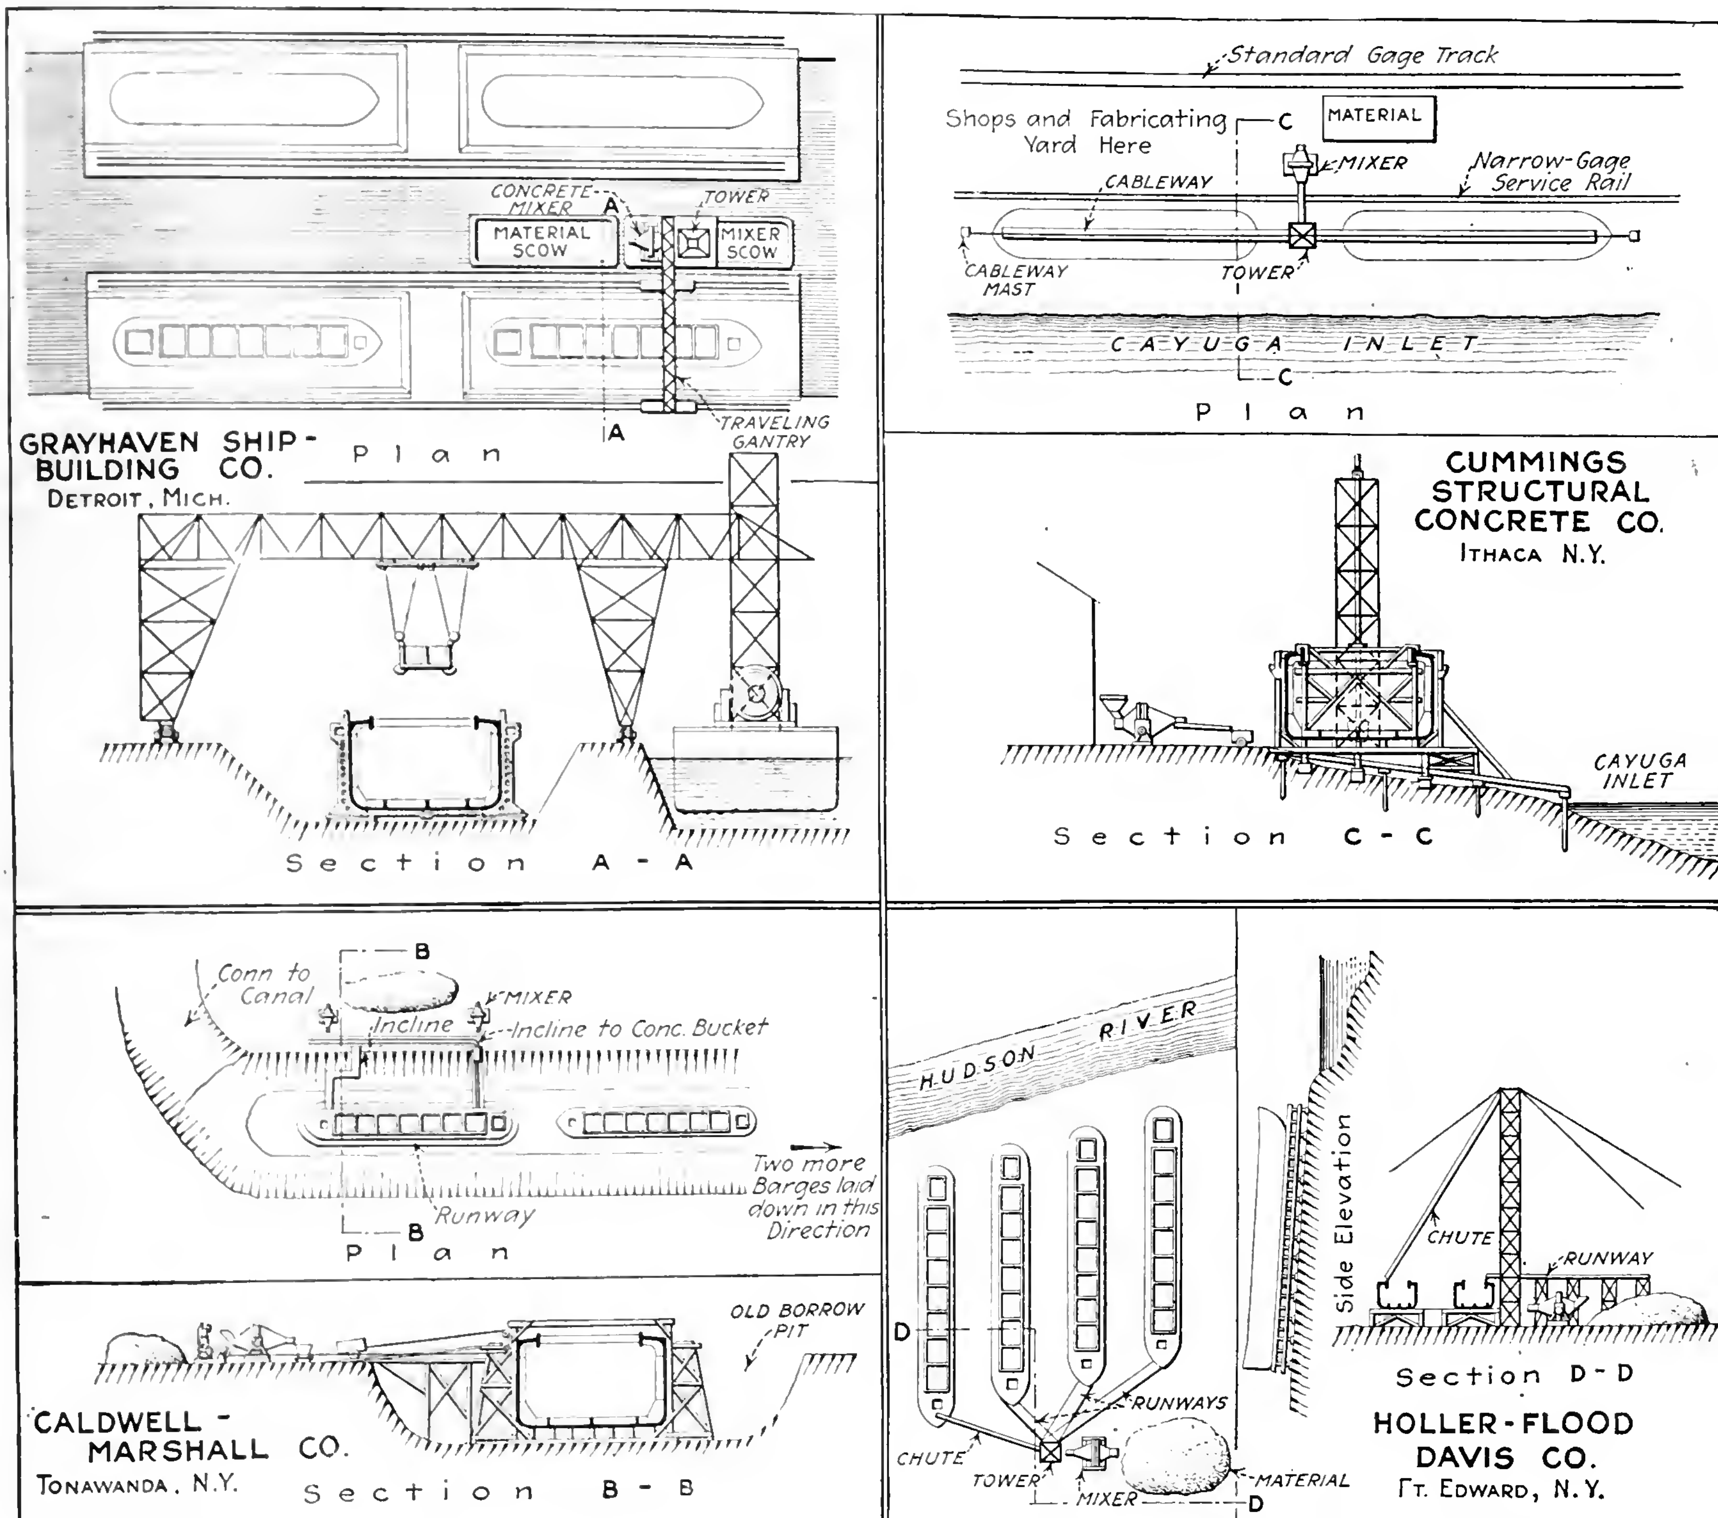


NEW YORK STATE CANAL CONCRETE BARGES UNDER CONSTRUCTION AT FOUR DIFFERENT YARDS

A primary difference is seen in the adoption by each of the four yards of a different system of launching, which reflects in the layout of the yard. A sketch of each of the four layouts is shown. At Detroit there is the remarkable dry-dock arrangement described in *Engineering News-Record* of Jan. 2, 1919, p. 21. In brief, this consists of four concrete-floored docks, two on each side of a lagoon leading into the Detroit River. The boats are built directly on these concrete floors in the dry; when they are completed the gates of the dock are opened, water is allowed to flow into the dock, and the boats are lifted from the base by hydraulic pumps and floated out into the lagoon. At Tonawanda advantage has been taken of a long borrow pit left in adjacent railroad construction. This pit is immediately alongside of the Ellicott Creek canal and separated therefrom by a narrow dike of earth. Each of the four barges contracted for here is provided with its own supports,

ranged in line along the borrow pit, as shown in the sketch, and launching is taken care of by a lock with about 4-ft. drop which lowers the barges into Ellicott Creek, a branch of the New York State Barge Canal, after they have been floated in the borrow pit. Provision is made for intermediate cross dikes so that the first barge completed, the one nearest the creek, can be floated out before the others are finished.

shop in the nearby city. The Detroit yard, on the other hand, is laid out for future shipwork of various sorts, and has full shop and mill equipment. At Fort Edward the contractor is also building wood barges, and has a large yard with self-sufficient shops and mills. The Ithaca yard, too, though designed for the present work, is well provided with shops and equipment. It is so located that one of the Barge Canal terminals can be



LAYOUT OF FOUR YARDS WHERE NEW YORK STATE CANAL 500-TON CONCRETE BARGE IS BEING BUILT

At Ithaca two side-launching ways are provided, dropping the barges into the inlet. Two barges will be built on each of the two ways. At Fort Edward there are four end-launching ways leading diagonally into the Hudson River. On each of the ways there will be built two of the barges contracted for. We have, therefore, two different types of float launching, an end-launching system, and a side-launching layout.

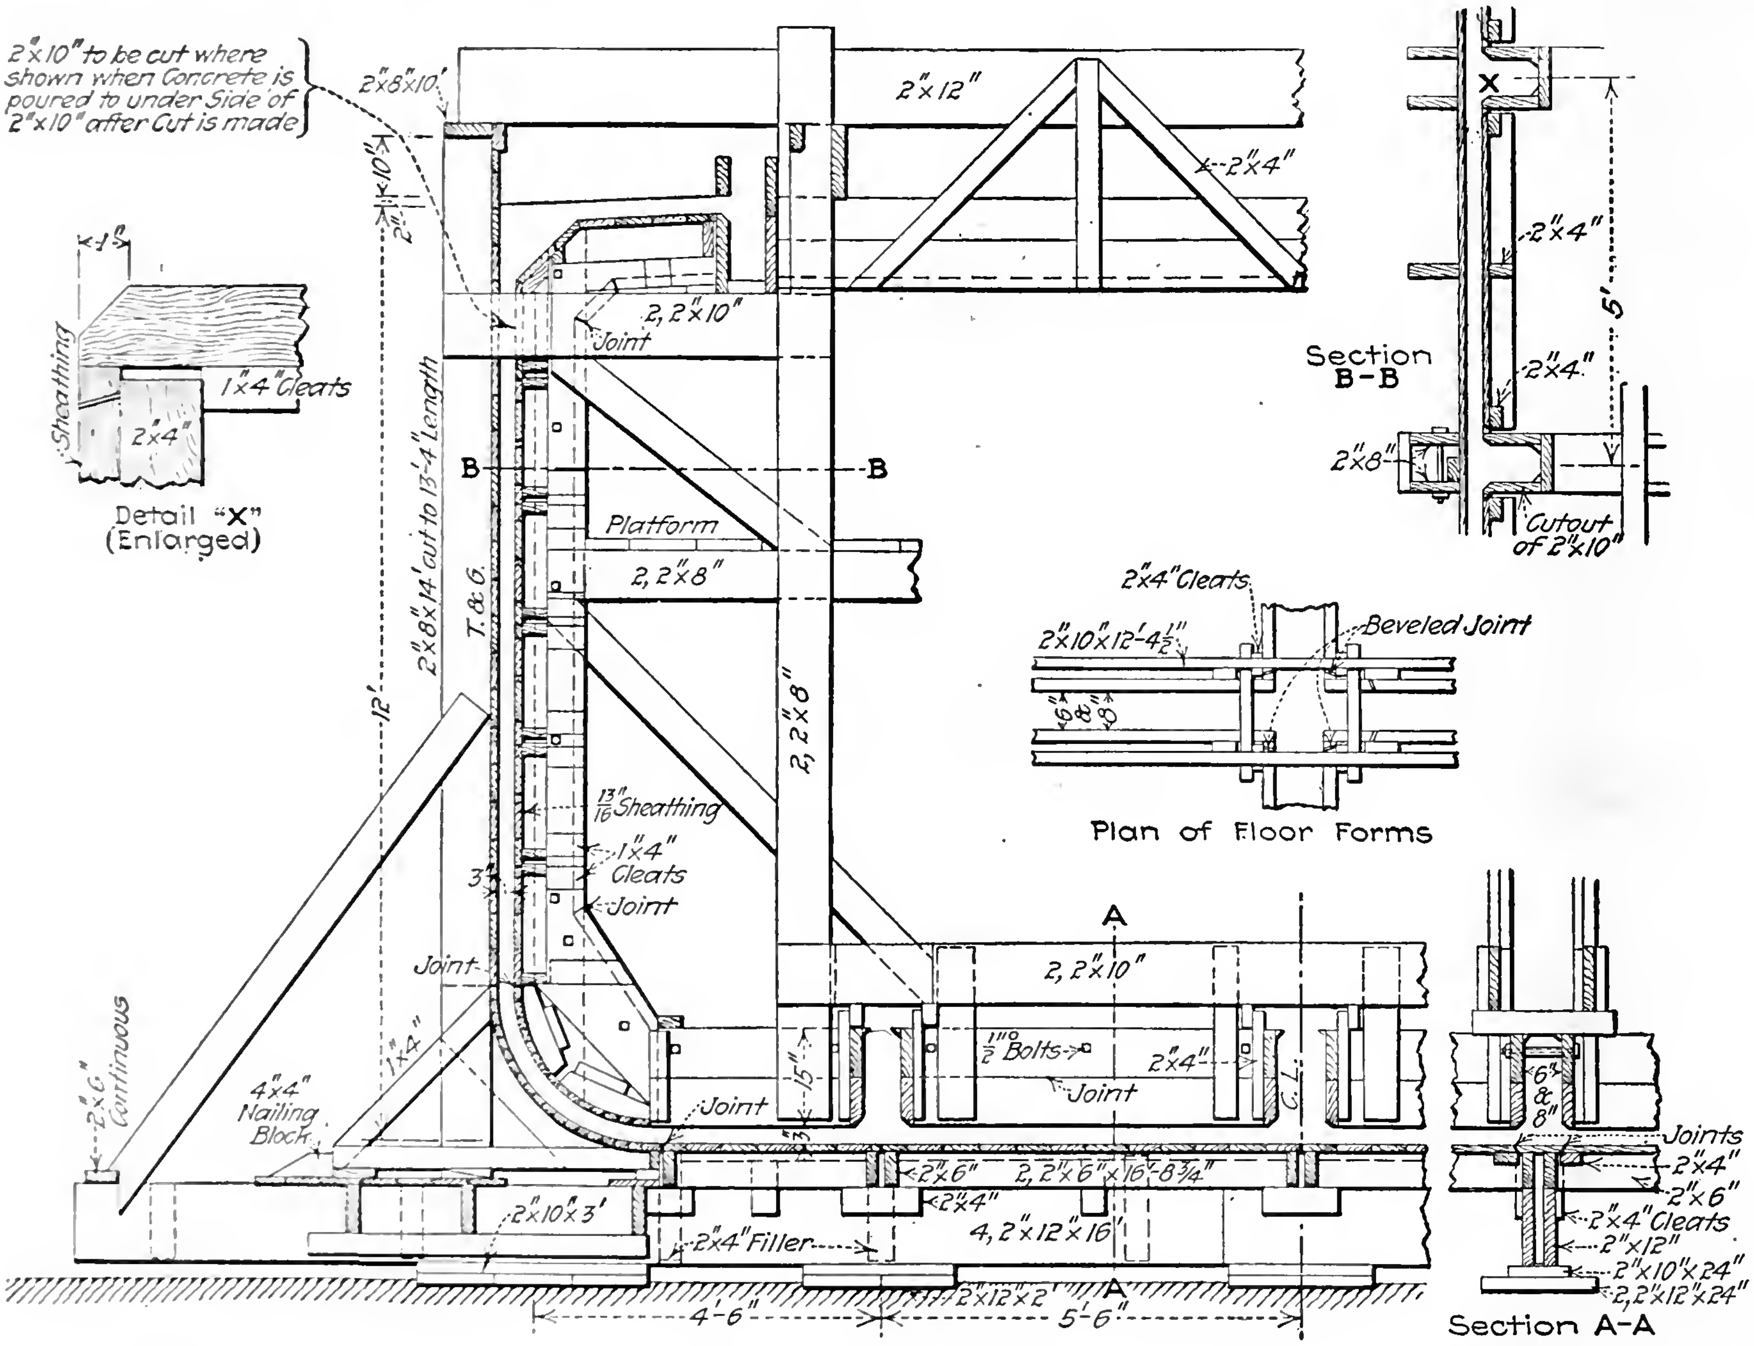
Yard equipment varies in the four yards. The Tonawanda plant is frankly temporary, laid out only for the four barges under contract. Its equipment is mobile and scanty. Carpenter work, both for forms and fitting out, is done, in so far as possible, by contract at a

utilized as a fitting-out dock, and the carpenter shop is placed alongside this dock.

The Government required that the barges be poured in one operation. This did not put any great burden on the concreting plant, because only about 120 yd. of concrete is involved, but it did make it necessary to set up a complete set of forms before any concreting was started. The yards, then, had the common problem of providing a complete form structure, comprising (1) supports or launching ways; (2) outside forms for the floor and for the shell—which latter included the warped surface forms for the bow and stern, and (3) inside forms for the frames and shell. These forms had to

be so arranged as to interfere as little as possible with the process of concreting, to be readily removable and re-usable, and to be of such design as to permit their removal clear of the barge when launched. In all cases, the barges were poured complete, the forms stripped for re-use in from one to two weeks, and the barge was launched in from two to four weeks after pouring commenced.

Supports or Launching Ways and Outside Forms—In all except the Detroit yard, where there is a concrete floor on which the barge is laid directly, the supports are timber frames on mudsills varying in design to suit the conditions of launching. In each case, the supporting frame extends far enough outside the barge itself to take the outside form posts and braces, when moved out away from the poured shell. On the supports rest the outside floor forms, so designed as to permit their ready removal.

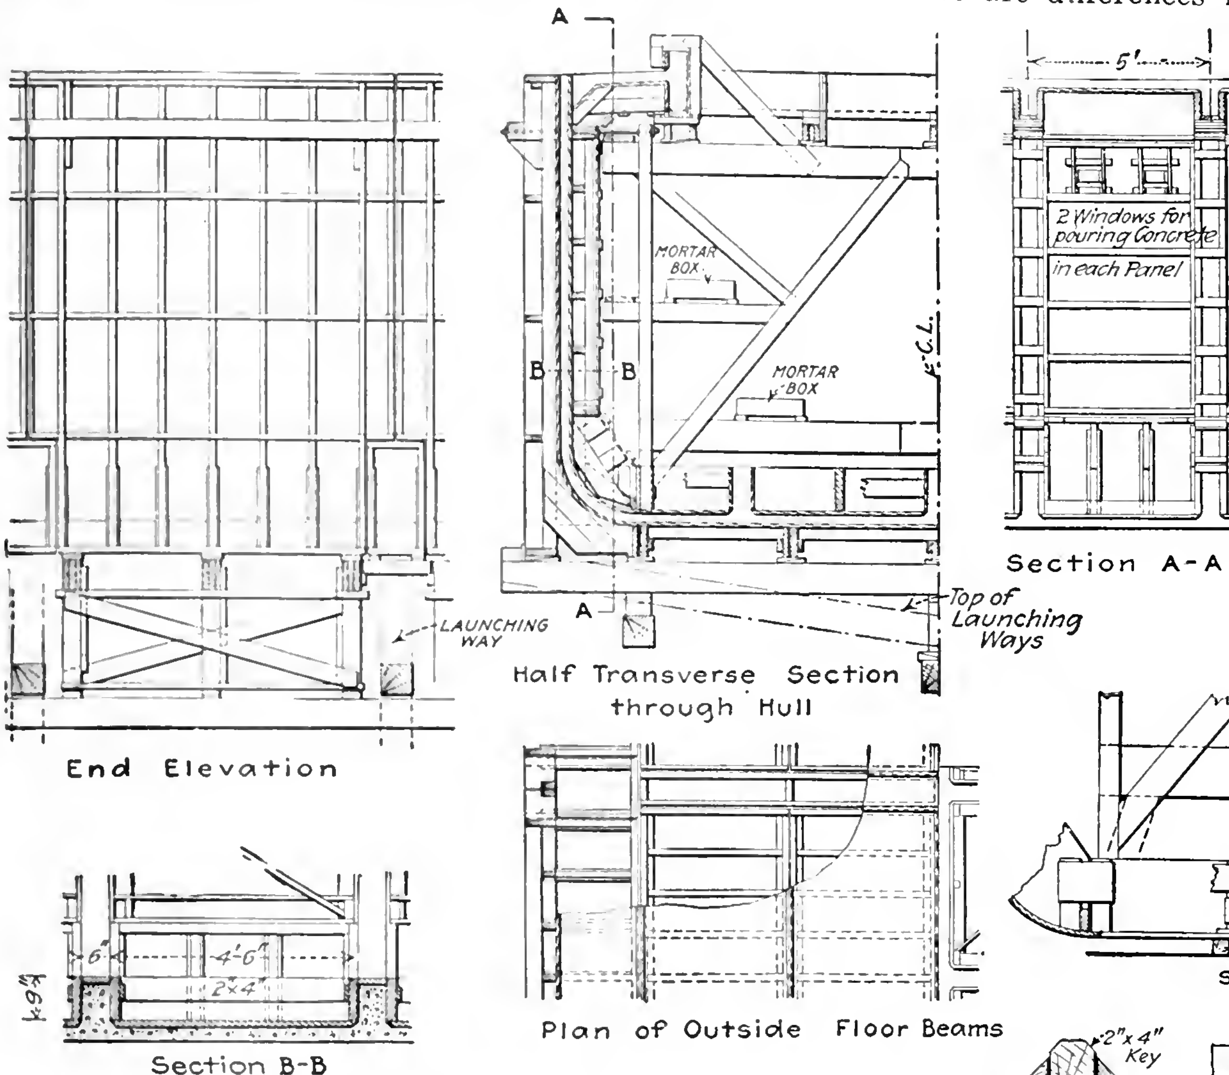


AT TONAWANDA, CALDWELL-MARSHALL CO. IS BUILDING CONCRETE BARGES ON STATIONARY SUPPORTS IN OLD BORROW PIT

In the Tonawanda yard, as shown in one of the drawings, longitudinal wooden sill footings reinforced with cross-beams on the ground carry transverse 2 x 12-in. planks under each of the frames extending to the floor. The bottom floor forms are in panels between the keelsons and the floor frames, and are held in place by cleats nailed to the transverse 2 x 12's. After the barge is complete these cleats are knocked out, and the bottom floor panels are dropped down and pulled out from under the boat, leaving 2 x 12's with the small piece under the frame. These latter are taken out piece by piece, and the boat is strutted up to the ground. The outside forms in the Tonawanda yard are in one piece, extending the whole straight length of the barge—that is, about 120 ft.; the tongue-and-groove lagging is carried on frames 5 ft. apart, as shown, which rest on wedges propped up from the ground. In stripping the forms these wedges are knocked out, thus dropping the whole outside form on its outward face and pulling it away from the concrete about 7 in. at the top. It can then be lifted out before launching by flotation takes place.

At Fort Edward an end-launching system is used, and longitudinal ways carry the whole boat during construction. The floor is supported, as shown in the drawing, on transverse 2 x 10's which are cantilevered out from the outside jack frames to meet at longitudinal stringers under the center keelson. There is one of these jack frames every 5 ft., and they are tied together in panels of 30 ft. The cantilevered floor-beams are bolted together when they meet at the center, to hold the whole floor in place during construction. The side frames which carry the lagging for the outside forms of the shell are propped up on wedges from above a transverse roller skid. When the boat is to be stripped the wedges are dropped from under the frames and floor, and

the whole frame in 30-ft. panels, with its cantilevered floor, is slid outward a sufficient distance to clear the outside launching way. The cradles are placed in this 30-ft. length, and the barge is supported on them. The process is continued along the whole length of the boat before it is ready for launching. The barge is built normal to the ways.

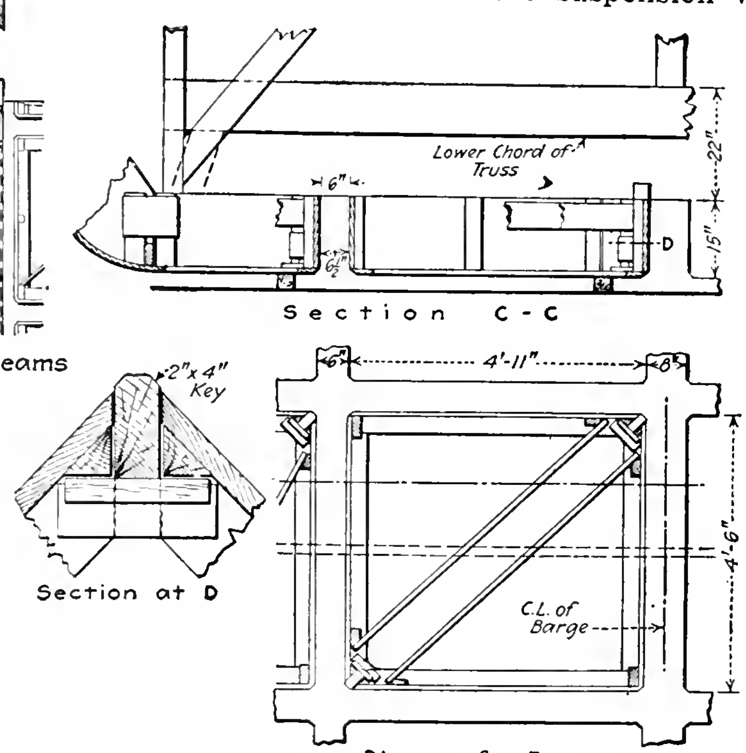


SIDE-LAUNCHING WAYS AT ITHACA

In the Ithaca yard the level floor of the main supports is strutted up from the sloping side-launching ways, and carries the bottom floor forms in panels of simple design. A separate drawing shows these forms in detail The panels are boxes with longitudinal stringers resting on wedges on the supports and carrying closely spaced transverse stringers on cleats. To dismantle, the wedges are drawn and the box is dropped. Outside shell forms are of different types for the shore and the water side. Because they have to be moved entirely out of the way before the barge is launched, the waterside outside forms were made in easily handled 10-ft. sections, with special panels at the bilge curve to permit the introduction of the launching cradles. In the first barge a similar design was used for the shore outside forms, because it was expected that the launching ways would extend shoreward of the forms, and provision was made to permit their placing. It was later decided that the ways need not extend so far, and the second set of shoreward forms was made in one piece for the whole straight length of the barge and was moved out bodily. The shore forms built for the first barge were used for waterside forms on the other way, and two sets of complete-length outside forms were made so that there were two full sets of forms available for the four barges.

In Detroit, as described in the previous article, the whole outside straight shell form is one piece backed against concrete frames, and is dropped by wedges and moved out bodily.

Inside Forms—There is a similarity in the design of the inside form framing in all of the yards, although there are differences in the method of taking care of the inside shell panels. In all the designs the inside forms are one structure, built up in its entirety before any concrete pouring is started. They consist of transverse timbers or trussed frames, every 5 ft. resting in the outside frames or studs and carrying by a dependent framework the floor-frame, side-frame and cantilever deck forms. Some of the designs intended that these forms should be at all times suspended from the upper truss work, but in construction the suspension was used merely as a stiffener, and the load of the forms was transferred by means of interposed concrete blocks, small pieces of stone, etc., to the floor steelwork, which in its turn was held a proper distance away from the bottom floor forms by similar pieces. The short cantilever deck was held everywhere by cross-frames extending out from the suspension structure and fastened also to the vertical frame forms, but at Fort Edward deck forms as well as the steel reinforcement were held in place by wires from the beams across the boat.



INSIDE FLOOR FORMS AT CUMMINGS YARD

According to specifications, each yard had some overhead framework on which tarpaulins or planks, for cover in inclement weather, could be placed. At Ithaca the whole framework is enclosed and steam pipes within keep the temperature fit for concreting even when the outside temperature is very low.

The inside floor panels vary somewhat in detail, though in each design there is used a form box between the keelsons and the frame. At Detroit this box is built up with wood screws and in the stripping

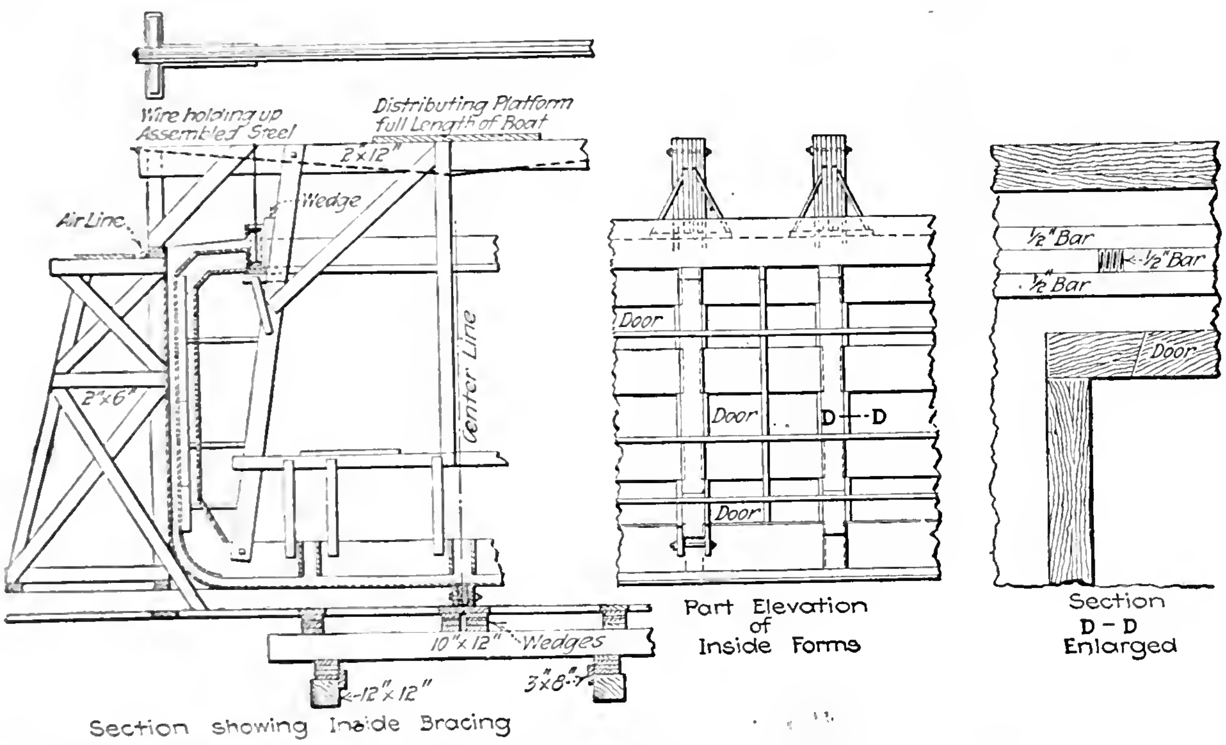
it is taken apart by unscrewing the fastening. At Tonawanda the four corners of the boxes are cut on a beveled joint, and the box is held to the true square by overhead 2 x 4's used as spacers. In stripping, the 2 x 4's are knocked out and the boxes knocked apart on their beveled joints. At Ithaca the boxes have a special corner key, shown in one of the drawings. This is knocked out, and the form falls apart. The Fort Edward yard uses a hooked system of box forms in all of the demountable panels. In the floors, for instance, the four sides are connected with ordinary door hooks at the corners and are demounted by the knocking out of the hooks.

Inside Shell Forms—Shell frame forms in all cases are of heavy planks held in place by braces from the inside form framing and serving as guides for the shell forms. In Detroit part of the side planks were left permanently in place as the nailing strips for the barge lining. In these yards the face form of these frames was continuous, but at Fort Edward there were windows left in the form for the concrete, on account of the method of pouring.

The inside shell forms have to be designed so as to permit openings up the side of the shell as the concrete is poured. It is manifestly impracticable to pour the 3-in. shell from the top, with assurance at the same time that the forms will be filled clear around the bottom of the bilge curve. In all cases, the bilge curve outer form is a part of the outside forms—a solid section tacked to curved studs attached to the jack frames—and the inner form is made up of lagging attached to a segmental form hung from the inner frame. This lagging is of narrow slats laid longitudinally.

In two of the yards, at Detroit and Tonawanda, the inside shell forms are in panels 2 ft. deep extending between the frame forms, and sliding against the bearing of these forms, as shown in the drawings. There is one less panel in the section between frames than is required to fill the full height, and in the beginning of the pouring the opening 2 ft. wide is left just above the top of the bilge curve. When the concrete reaches the top of the bilge curve the panel next above is dropped down flush with the top of the bilge curve, leaving the 2-ft. opening then in the next panel above. The process is continued until the entire shell is poured. The two drop-panel systems differ somewhat in detail, as shown in the drawings.

In the Ithaca yard the inside shell form is built in an integral panel extending the whole depth of the boat and the distance between frames. Small windows are then cut in the form at regular intervals, with an inside bevel on the joint. The wood window is then removed while the concrete is being poured, and as soon as the pouring reaches the bottom of the opening the gate is put back and buttoned tight against the standing part of the form. The sides of these forms are beveled, to permit their removal, but it proved to be difficult to take them out, even with this provision. At Fort Edward panels 2 ft. in depth and frame spacing in width are provided for the whole depth of the shell. These are buttoned on against one another, to resist the movement toward the outside of the boat, and held with door hooks to the studs, to resist an opposite movement. Panels are taken out one at a time as the concrete pouring rises in the shell.



AT FORT EDWARD, N. Y., HOLLER-DAVIS-FLOOD CO. BUILDS CONCRETE BARGES ON END-LAUNCHING WAYS

Outside and inside shell forms are all tongue-and-groove material, but matched lumber is used for the inside for the warped surfaces.

Four different systems of outside end forms are used. Both bow and stern of the canal barge are curved, the stern having a warped curve for its full height, and the bow being warped only up to the top of the bilge line, above which the only curve is the one in the horizontal plane. Complications of these curves, however, forbid the continuation of the regular system of forms. In Detroit, mortar molds are used for both ends of the boat. These molds, as described in the previous article, are divided into three parts, and are slid out on the jack frames to be used over again in other boats. At Fort Edward an attempt was made to cover the curve studding with surfaced lagging and a tin form. This did not prove entirely satisfactory, because the tin was wrinkled by hickeys while placing steel and left a wrinkled surface on the concrete simulating too vividly the mold from which it was formed. At Ithaca narrow lagging was bent around the templet-formed studs, the slats being made of quarter-sawed cypress. Similar bending of slats was used at Tonawanda, but oiled elm was used for the lagging. In both these cases the fitting of the studs to the proper curve and the bending of the lagging made a nice piece of carpentry. Inside end forms in all cases were small boxes cut to the varying curves of the ship and fitted in between the frames.

Placing Steel—In all the boats, the floor steel was laid first and the side shell steel tacked into place on

the outside form, wired together, and then braced out from the outside form with small concrete spacers. At Ithaca, however, in the later boats, special clipped spacers with protruding hooks at proper locations for the longitudinal steel were attached against the side of the boat, and the longitudinal steel was dropped into these clips. The clips were allowed to remain in place. The strips against which they were nailed were removed when the forms were taken down, and the opening was plastered up. In some of the boats, longitudinal rods were welded by spot welding. In others, they were overlapped and wired. In three of the boats, the steel frames were prefabricated, and lifted or carried into place in the boat. At Fort Edward the stirrups on the frames were electrically welded, but in the other yards they were wired. In the Tonawanda yard all the frame steel was erected and fabricated in place in the boat.

A—Oiled Elm Bent Around Frames at Tonawanda

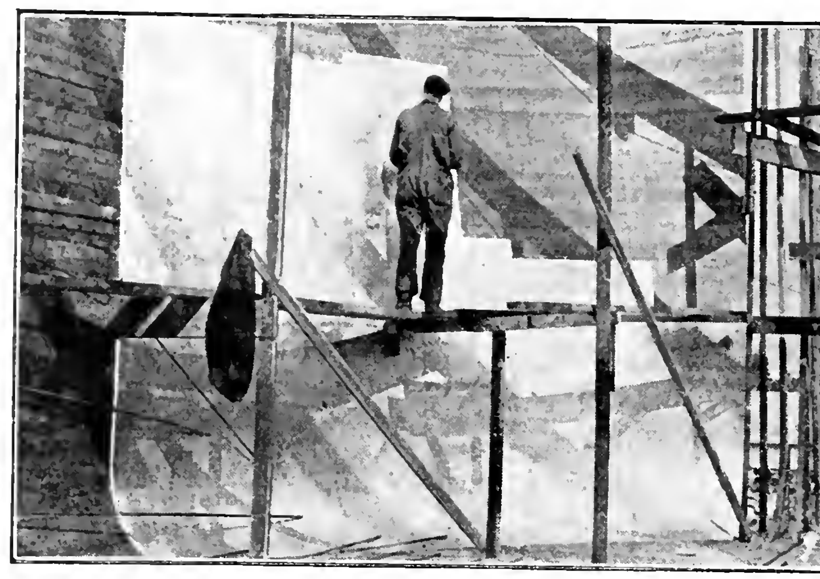
END FORMS DIFFERENT IN THREE YARDS

Concreting Plant—The problem in concreting one of these barges was not in producing the concrete, nor even in getting it to the boat. Both of these processes will, in general, be held up by the difficulty in placing concrete in the narrow forms, congested as they are with steel and difficult of approach through the forest of supporting framework. As described in the previous article, the Detroit yard has a special gantry crane, traveling over the boat, which drops the concrete, where required, from a bucket. All the other yards use a buggy wheeling system to get the concrete to the place of deposition, although in the first boat poured at Fort Edward a chuting system, shown in one of the sketches, was used. This did not prove satisfactory, and for further boats there were built from the concrete mixer trestles over which the buggies were wheeled to the boats themselves. At Ithaca the concrete mixer is located immediately alongside of the material pile between and just off line of the two ways. The material enters the yard by rail, is dumped alongside the mixer, feeds through the mixer into a car, which is pushed under the tower and elevated to runways extending out along the center line of the barge from the upper deck level to the tower.

At Tonawanda an extremely simple plant is used. Two concrete mixers under a canvas cover are moved along the bank of the borrow pit as required, the materials being dumped alongside of them as they move from boat to boat. The timber runway runs alongside the dump end of each mixer to an incline up to the platform along one side of the barges. The concrete is dumped into an ordinary concrete barrow and pulled up the incline with a line leading through a spool on the barge back to the mixer.

In every yard but Ithaca, where a center runway was used, there was a runway at deck level around the outside of the boat. All the boats had runways on the top of the floor frames, but in Detroit these were used only for the men themselves to work on, the concrete being chuted to the bottom from a runway half way up the frame, on which runway were mortar boxes receiving concrete direct from the gantry bucket. In the other boats, however, the buggies or boxes—and at Tonawanda mortar boxes on small industrial dollies—were kept on the bottom runway and were filled from chutes from the upper runway. The men then shoveled from the boxes into the floor and lower side forms. In all cases, as the shell concrete rose, the midway runway was used. These midway runways were all supported from the inside frames, except in the case of Fort Edward, where the midway platform was hung by bent reinforcing rods, improvised for the occasion, to the trusses across the boat. In all cases, one form or another of portable hopper, made up either of straight pieces of wood or of bent galvanized iron, was used to facilitate the pouring of the concrete into the side forms.

C—Quarter-Sawed Cypress Matched on Frames at Ithaca



B—Tin Tacked on Lagging at Fort Edward

In general, the order of pouring was as follows: Bilge curve, floor frames, keelsons, floors, side shell and deck. The principle followed was to lead the concrete into the open, getting the benefit of the course of air flowing ahead of the concrete. Pouring began at the top of the bilge curve, and when the concrete began to tail out on the floor, it was reasonably certain that the curve was filled. Likewise, when the floor frames were poured, concrete tailed out onto the floor.

Following the general practice on the Emergency Fleet concrete ships, mechanical hammers were used to vibrate the sides of the forms and agitate the concrete so that it would run around the curves of the bilge and into the frames. At Detroit and Tonawanda electric hammers were used. In these cases, the whole inside framework of the boat was wired with plug outlets into which either hammer connections or electric-light connections could be placed. At Ithaca and Fort Edward compressed air was available, and air hammers were used. No difference in the effect of the two types has been noticeable.

At Fort Edward the keelsons and floor frames were

BENDING STEEL WITH BULLDOZER AT FORT EDWARD

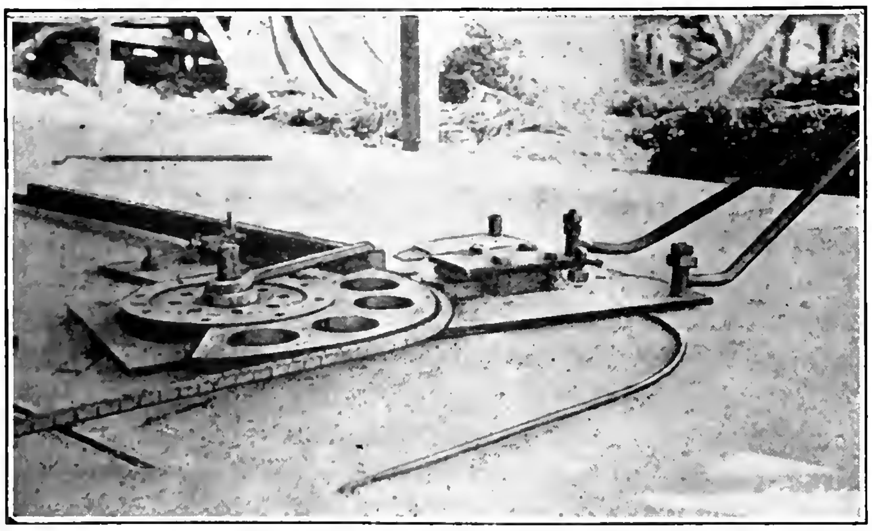
first poured, then the bilge curve, and then the side frames through the windows noted above. The contractor here felt that he could not be sure that the vertical side frames would be completely filled by pouring in the shell forms, as at the other yards.

Hand work predominates in handling the materials in all of the yards. At Detroit the transverse moving gantry is available, and floating derricks alongside can be used for heavy material, and are used in the placing of the transverse steel frames. At Ithaca two hand-operated cableways have been installed. These cableways operate between the central tower where the concrete mixer is, and two gin poles are set up at either end of the adjacent boats. The cable is continuous around the large spool at the base of the tower, up to the top of the tower, across over the boat, down to the bottom of the pole and under the boat and back to the spool. It is controlled by hand movement on the spool, and it carries an ordinary triplex block, also hand-operated. In the other two yards there is only gin-pole control of the heavy material. All of the boats are left open at the end as long as possible, so as to permit the ready horizontal transference of material into the boat during construction.

In all the yards aggregate of the same size—under ¼ in.—is used in a mixture which becomes 1:2 mortar. At Detroit a Detroit River gravel is brought in by a barge. At Ithaca a Ludlowville gravel is brought down via the lake. Niagara grit is used at Tonawanda, and at Fort Edward iron-ore tailings brought from the mines at Port Henry. The latter are somewhat dark in color, but make a concrete which tests very high in strength.

Bending and placing is the most laborious operation in the barge-construction steel. Small pieces are bent by hickeys either on the field or on the boat, but for the 1-in. steel bending different devices have been developed. At Detroit the bender with its main reaction against a cast-iron segment of the proper curve has been set down into a concrete floor. At Fort Edward bulldozers are used which crimp the steel around the curve

RADIAL FRAME AT ITHACA MARKS LIMIT OF BENDING



AT DETROIT, BENDER FOR LARGE BARS IS SET IN CONCRETE FLOOR

step by step. The work is very slow and not particularly satisfactory. At Ithaca a crimp bender is also used, but a chord system of bending has been developed which makes the work quite rapid. On the outlying radius, beyond the bender, there has been set up a light frame on which are marked the steps of bending for every inch on the rod at the crimp. One man stands at the bender, moving it along inch by inch, while the other man pulls the end of the rod around to its proper mark on the circumferential frame. At Tonawanda a heavy cast-iron grating made up of 2-in. pieces with 2-in. openings has been set tight into a bending table. On this grating is marked the proper curve, and the bending is done by hand by dropping dogs into the openings in the grating as the bend proceeds. This simple device works admirably.

What Shall Be Done About The Railroad Question?

Francis Lee Stuart Reviews the National Railroad Situation and Proposes Return to Private Ownership

After reviewing the facts which led up to Federal control of the railroads, Francis Lee Stuart, lately chairman of the Budget Committee of Eastern Railroads, proposed before the New York members of the American Society of Civil Engineers, Feb. 5, the return of the roads to private ownership as soon as enabling legislation can be passed. In reply to the question, "What shall the Government do with the railroads—Government ownership, or Government control for five years, or return to private ownership as soon as possible?"—he made the following statements:

Politics has no conscience, business morals or responsibility, and the danger to our methods of government from the political control of the railroad employees, possible and probable, under Government ownership prohibit its serious consideration.

From an engineer's standpoint, this country is young, and its natural resources have hardly been scratched, and an experiment in Government ownership would be extravagant, unfortunate, and undesirable on any basis, but primarily because it destroys the reward for initiative and sound judgment in the greatest field necessary for the proper development of our country and our national prosperity.

From the public's point of view, Government ownership throttles competition, which is a necessary incentive for proper service to the people in every part of the country and every city in the land.

On Control for Five Years

Some of the things which were ordered with propriety during the war, which should be undone at once and not five years hence, are:

The traffic departments of the various railroads, which were dispersed, should in great part be reassembled and rehabilitated at once.

An immediate abandonment as a national effort of an attempt at standardization of all manner of railroad necessities and methods. Such standardization, while it has a certain apparent first-cost economy when applied to quantity productions in the scheme of things in this country, tends to inefficiency, and should be a local question only in a limited locality. Our tools and methods are so crude that the national efforts should be to improve, not to standardize.

The horizontal raise in railroad wages of the entire country in one order which was necessary during the war is a pernicious destroyer of individual discipline, and debauches and atrophies the ambition of the men receiving such increase, and should be abolished in time of peace for responsible bargaining between employers and their own employees, as soon as possible.

The discomfort of the public, some of which was necessary during the war, should give way to even better facilities than offered before the war, the direct tax of an increase of passenger rates should be reduced to a minimum, even if an indirect tax of increased freight rates is necessary to pay the bills. The movement of the people freely around and about our country should be encouraged as increasing happiness and social-well-being, and tending to a unity of spirit which is good for the body politic.

The terminal problem, which was made so acute by lack of ships and storage facilities, is largely one of changing our commercial methods, pooling facilities, and providing for the prompt unloading of cars. Belt railroads are needed and should be built in many places, but the matter is a local one peculiar to each community, and best handled as a financial policy of such community and not by the Federal Government.

We have great national efforts to make in world affairs, and the sooner we put the vim of an owner's interest back of the largest business interest in the country the better.

Return to Private Ownership

This country is so young and undeveloped that the railroad should exist and be encouraged primarily for the development of our material welfare—and, for the good of all, the railroads should be returned to their owners as soon as possible, so that their growth will naturally follow the normal business needs of the country, tested by business standards, and not directed into any predetermined course which would be determined by a centralized Governmental agency.

Returning the roads to their owners under old conditions would mean financial chaos in the country, and some legislation, with certain Governmental controls, is absolutely necessary.

The normal growth of our country requires that the railroads spend in the next five years at least $4,000,000,000 for improvements, betterments, and normal growth of our transportation service, and a continuing and enlarging amount thereafter to meet our growing needs. While the Government finds it necessary to put out varying issues of Liberty Bonds, it seems best that they buy the securities of the railroad as needed until the public regains confidence enough to take the investment out of their hands. This will require a possible advance of from $1,500,000,000 to $2,500,000,000, for which the railroads could be charged a high enough annual interest charge, over and above the cost of the money to the Government itself, to pay off the debt within 20 or 25 years.

The principle of a fixed financial policy and the control by the Government necessary to carry out such policy under all ordinary business cycles should be made a law by Congress. The control should be of an enabling nature and not more restrictive than is necessary, and might at the present time well consist of:

1. A control of rates initiated by the carrier. The rate question is largely an artificial issue and little understood by the public. The shippers of the country are chiefly interested in rate relationships, and the ultimate consumer in the amount of the rate, as he really pays the bill. We hear of the shippers through their lawyers, but the ultimate consumer is rarely heard, because his indirect tax due to the rate alone is so very small. There are possibilities in a more logical rate structure for settlement of most of the misunderstanding between the public and the shipper, and between the shippers themselves, for which the railroads usually

"hold the bag." In connection with the control of rates, the Government should have an unbiased economic study made for a more logical application of rates than at present.

2. The wage question of the railroad employee, like other inflations of the war, will be settled sensibly by public opinion. It does not seem a proper Governmental function to settle wage scales, and it is for the best continuing interest of labor itself that such questions should be returned as soon as practicable to be settled between employers and employees. It is necessary, however, that the Government take cognizance of such matters in the control of rates.

3. A control of unproductive expenditures required by the public, and particularly as to the grade-crossing elimination question, which threatens to be of serious financial importance in the near future, so that due cognizance may be taken of such expenditures.

4. A control of issue of securities for improvements and consolidations, and of the necessary railroad accounts. Generally, the weak lines should be consolidated with the strong, and the large lines prevented from becoming so large that they eliminate competition from any section of the country.

5. A control in safety matters.

6. A recognition that for the continuing solvency of the properties the voice of the general public, whose welfare is at stake, and the voice of the owners of the properties, should be heard with that of the shippers and representatives of the employees.

Principles for Legislation

In my opinion, the proper principles for legislation for a fixed financial policy should be based on an average railroad efficiently operated, receiving, as a minimum, a fair profit for the transportation it has to sell, and that fair profit must include: (1) An adequate going return on the investment over the cost of proper service to the public; (2) a return for such money as is borrowed for improvements required by the growth of the country, which will include the cost of the money plus an added equity to the corporation in compensation for extending their credit and brains as collateral for such money; (3) the further right to build up such surplus as this class of business, wisely conducted, should have in reserve for emergency.

With the principles of a policy fixed, and controls whereby it may be made effective, the means for carrying out the purpose could be more flexible and could consist of a number of commissions with some coördinating force, all safeguarded in certain cases by right of appeal to proper courts.

The entire matter is of such importance to the whole country that, if this session of Congress cannot settle the question, then an extra session should at once be called for this purpose.

Courses in Industrial Hygiene and Medicine

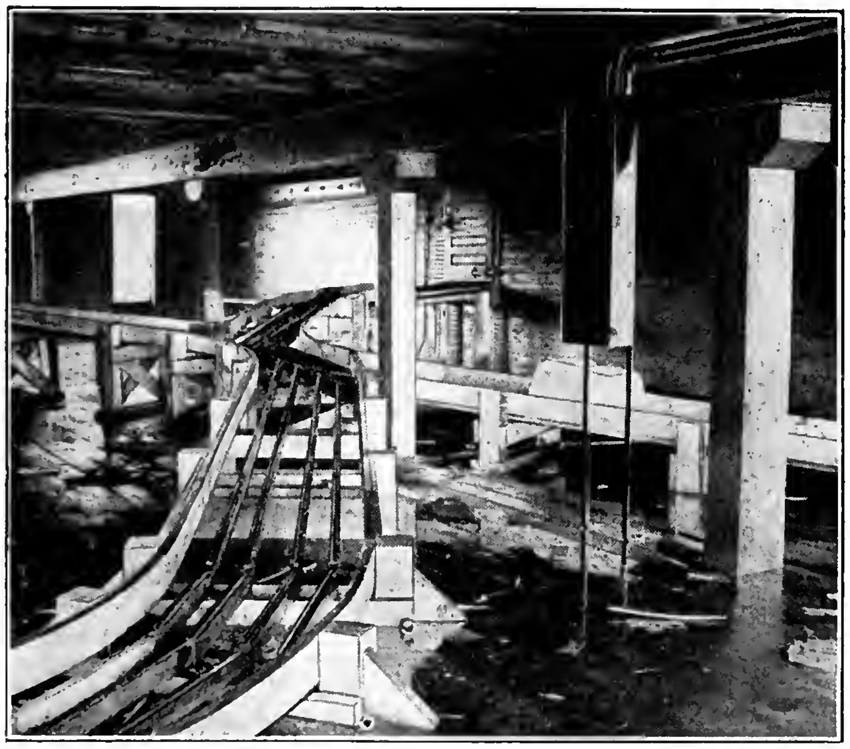
A course in industrial hygiene and medicine was recently given at Yale University under Prof. C.-E. A. Winslow, and a similar course is to be given at Ohio University, according to a statement issued by the Working Conditions Service, Department of Labor.

New Car-Icing Plant Accommodates Twenty-Eight Cars

Modern Ice-Handling Machinery Operated by Electric Motors—Three-Deck Platform Is More Than 1000 Ft. Long, With Conveyor Service

By E. F. Ackerman
Assistant Engineer, Illinois Central Railroad, Chicago

At Waterloo, Iowa, the Illinois Central has replaced its old car-icing plant, erected 32 years ago, by the largest plant now operated by that company. Modern ice-handling machinery inside the building, gravity conveyors, and three-deck platforms over 1000 ft. long, make the new plant far superior to the one it replaces, as 28 cars can be spotted and iced in one and one-half hours without moving the train, whereas only nine cars could be supplied by the old plant, and it required four hours to ice a train. Instead of hand labor, the new plant uses electric motors for mechanical handling; loss from melting in the new plant is practically nil, because it is built like a refrigerator with insulated walls and air-tight openings. The plant is located on the main line between Omaha and Chicago, for the purpose of re-icing the refrigerator cars loaded with fruit and meat on their way to Eastern markets.



INCLINES TRANSFER CAKE ICE TO OUTSIDE PLATFORM

The new plant consists of three separate units, combined in one large building which has a ground area of 59 x 282 ft. At either end of this building is a storage room 55 x 124 ft. and 35 ft. high in the clear, each with a capacity of 5000 tons of ice. Between the storage rooms is a three-story building 30 x 55 ft., known as the ice-handling room. The first floor is the receiving room, the second floor is used in taking cake ice from the storage room, the third floor is the crusher room and salt-storage room.

Along the side of the building is a three-deck platform which extends beyond each end, to a total length of 1008 ft. The first deck is the receiving deck, and is built on an incline, so that ice taken from the cars slides down onto two conveyors, each 123 ft. long and with a capacity of 24 full cakes per minute. These con-

ICING STATION WITH OUTSIDE PLATFORMS 1008 FT. LONG FOR ICING 28 REFRIGERATOR CARS

veyors push the ice to the receiving room, in which slides are built which convey the ice by gravity to the combined elevating and lowering machines, of which there is one for each storage room. These elevating and lowering machines have a capacity of 16 full cakes per minute, and are arranged so that ice can be taken from the receiving room and elevated to any level in the storage room. They can also be reversed, to take ice from the storage rooms at any level and convey it to the different floors of the ice-handling room. Each of these machines has two motors; one operates the hoist and the other operates the brake, which is so connected that when the power is cut off from the hoist motor the power of the brake motor is automatically turned on, and this in turn applies the brake.

Conveyors Can Be Reversed

On the second floor of the ice-handling room slides are built which take the ice from the elevating machines and deliver it by gravity to two conveyors, which run to each end of the second deck of the platform and are 484 ft. long. Ice can be taken from these conveyors at any point along the platform. They have a capacity of 18 full cakes per minute, and can be reversed so that the ice not used is run back into the storage room.

On the third floor, or crusher room, ice is taken from the elevating machines and by gravity runs down inclined slides into two Creasey ice crushers. These crushers have a capacity of 60 tons of ice per hour, and are located on an elevated platform so that the crushed ice can be dumped into carts which are then hauled by men onto platforms and dumped into a movable chute; this runs on rails along the entire length of the third deck, and conveys ice into the hatches on top of the refrigerator cars.

In the ceiling of this crusher room is built a large hopper-shaped salt bin of 30 tons capacity, with a gate in the bottom to deliver the salt into cars which are hauled on the top deck of the platform to hoppers placed at every third post. Under the receiving platform is a concrete hopper with a concrete chute, into which salt is dumped from cars and run by gravity into buckets bolted on an endless belt. This conveys the salt into salt bins in the roof of the crusher room.

The entire building is built as a refrigerator room, the walls being double and consisting of two thicknesses of ⅞-in. sheathing nailed on 3 x 10-in. studding, with heavy roofing paper between on the inside, and one thickness of ⅞-in. sheathing and 6-in. No. 115 lap siding with heavy roofing paper between, nailed on the outside between the sheathing and the studs. Granulated cork is packed to a height of 10 ft., and above that fine shavings are used to the under side of the rafters.

The roof is double, the under side of the rafters being sheathed tight with ⅞-in. sheathing, and the top of the rafters is sheathed with 1⅛-in. sheathing open at the eaves, where a small monitor is built at the peak of the roof the whole length of the building. This forms an air passage between rafters and keeps the under side of the roof cool.

The wall and floor foundations are of concrete, the floor being built of 4 x 4-in. cypress sleepers, upon which 2 x 6-in. rough cypress planking is placed 1 in. apart, to form an air passage and allow drippings to run off into the sewer. All the doors to the storage room and crusher room are double refrigerator doors.

Construction Under Severe Conditions

The erection of this plant was accomplished in one of the most severe winters ever known, work being carried on in temperatures as low as 12 deg. below zero, and material being shipped from the East in the worst snowstorm. The cars with machinery were stalled in the snow for months, and the first ice had to be stored with the aid of a steam engine and an inclined conveyor.

The work required a total of 2616 cu.yd. of excavation, 640 cu.yd. of concrete, and 320,000 ft. bm. of lumber. The plant was planned and designed in the office of F. R. Judd, engineer of buildings, Illinois Central R.R., and the writer was locally in charge for the railway company. The construction work was done under contract by the J. W. Zitterell Co., of Webster City, Iowa, with H. Bearman as superintendent.

Surveyed 38,136 Square Miles Last Year

Detailed soil surveys covering 38,136 square miles were made during the fiscal year 1918 by the Bureau of Soils of the United States Department of Agriculture. Prior surveys of 445,825 square miles make the total 483,961 square miles. Twenty-two states and four bureaus of the Federal Government are now actively coöperating in this soil-survey work.

Operating an Employment Bureau for Civil Engineers

How a Technical Society Conducts a Registration Office—Tries Also to Place Employed, But Not Satisfied Men

BY C. S. RINDSFOOS
Chairman, Registration Bureau, Cornell Society of Civil Engineers, 30 E. 42nd St., New York

UNEMPLOYMENT in the engineering profession threatens to become serious in the near future, so that greater interest than ever before is being displayed by the various Governmental and society employment bureaus which have operated, until recently, in a most perfunctory manner. How the Registration Bureau of the Cornell Society of Civil Engineers is now being conducted may therefore prove of interest to many other similar societies that have such work under way or in contemplation.

The writer believes that—important as is the question of assisting the unemployed, in which class discharged soldiers and sailors would fall—there is one possibility of service, on the part of such bureaus, of much greater and abiding importance; namely, the shifting of the man who is doing unprofitable, uncongenial or unsatisfactory work into work that he can do to better advantage—in short, in helping the "misfits." Nothing is more sad than to see a man doing work for which he is not fitted. Many a man starts on the wrong path or becomes sidetracked and, being burdened with a family or other private responsibilities, lacks the time, capital, ability or nerve to change to that position where his native talents have a chance to display themselves. At this juncture a helping hand, pointing the way to greater opportunities, is a fine thing not only for the man but for his profession and society in general, tending to efficiency and greater productiveness.

EVERY MAN CATALOGED

Keeping this in mind, the bureau took the first step in its plan by cataloging every man who had ever attended the college, whether he was satisfactorily employed or not; whether he was a beginner or a man of high attainments. A questionnaire with inquiries of every sort necessary to a knowledge of a man's capabilities was sent to every Cornell civil engineer, some 2000 in number. The idea in cataloging all the men was, first, that in no other way could it be determined how many were desirous of a change; second, that any man at any time might become a candidate for a new position; third, that every man, practically speaking, will consider a change if offered sufficient inducement either in salary, responsibility, or chance for service, and fourth, that the sympathy and help of the satisfied men was necessary to the bureau and that they would support a bureau more readily if they were a part of it and received the notices sent out from time to time.

These questionnaires are four-page, letter-size, and are filed by number (without reference to the alphabet). All correspondence with reference to a man's record received subsequently is filed with the questionnaire, so that the questionnaire becomes a folder with complete data, up to date, and immediately available. Follow-up cards are sent from time to time to keep the records up to date, and these also go into the questionnaire folder.

A card index (size 3 x 5 in.) is maintained to go with the questionnaires, arranged alphabetically, each card containing the name of the man and his number—nothing more. By means of this index, given a man's name, his number can be immediately determined and from the number his questionnaire is located.

Another card index (size 3 x 5 in.) is maintained and arranged by classes. This index is divided into two main groups, labeled "satisfied" and "not satisfied." Unemployed men are filed in the latter group until employed, when their cards are transferred to the "satisfied" group. Should a man become dissatisfied with his employment, his card is transferred from one group to the other, without disarranging the regular files.

Each of the two main groups is subdivided by salaries. For example, cards of all men who place a value on their services of, say, $250 per month are placed between the tabs 200 and 300. Men who value their services at, say, $350 have their cards placed between the tabs 300 and 400, and so on. Should a man's value increase so that his subsequent reports show that, whereas at one time he would consider a $250 position and his card was so filed, he now would consider nothing less than $350 his card is simply transferred, without deranging the regular files.

Each salary group is further subdivided by symbols which indicate whether a man is a candidate for an "executive," "administrative," "engineering," "sales," "clerical," "commercial," etc., position. The card is so ruled that the symbol and salary may be changed from time to time, so that a clerk, without even knowing what the symbols mean, can place the card in the right slot with a maximum of speed and accuracy. For example, if the last symbol on a card is 1-450-NS his card belongs in the "Not satisfied" group, subdivision 400-500 (salary) sub-subdivision 1 (executive).

Suppose an employer calls for a man to fill the following position: (1) Superintendent of construction; (2) salary, $450 per month; (3) age wanted, 30-40; (4) type of work, factory building, reinforced-concrete, pile foundation. It requires a moment to pick the group of cards classified "administrative—400-500." The corresponding questionnaires are then taken from the questionnaire file and those selected which represent men of about the age and professional attainments required. Any special requirement such as "married man preferred," "man capable to design as well as construct wanted," etc., can be determined from the questionnaire. An exact copy of each questionnaire of each logical candidate is then sent to the employer, and the original is returned to the file. A metal signal is then placed on the card of each man recommended, for purposes of follow-up. A notice is also sent to each man, telling him he has been recommended for the position.

It will be seen that every effort is made to serve the employer by only sending "logical" candidates. If no man seems available, the inquiry is referred to one of the other college bureaus, which reciprocate in like manner.

Many other forms and devices for follow-up purposes, for obtaining inquiries from employers, and to save dic-

tation in correspondence, are used, but it is thought the part here explained gives the gist of such features as are novel. The plan was evolved after a careful study of many other systems, and it is believed that by combining desirable points from several with ideas of our own a good workable system has resulted.

Loss of Head in Sewage Sludge Pipe at Toronto, Ontario

Experiments Made on 12-Inch Cast-Iron Sludge Main After Five Years of Use Give Value of n = 0.0168 to 0.0181

By T. H. Nevitt

Superintendent of Sewage Works, Toronto, Ont.

Owing to the necessity of obtaining some data as to the loss of head due to pumping sludge through pipes, an experiment was made at the main sewage-disposal works, Toronto, on the 12-in. cast-iron sludge discharge main. The data were required for use in a report on sewage disposal.

The sludge experimented with was obtained from the sedimentation tanks, and was not more than 10 days old. This sludge was released from a tank through four 8-in. valves situated at the apex of the bottom hoppers, and flowed through a 10-in. cast-iron pipe, on a 2% grade, to a sludge well in the pumping station. Here it flowed into an 8-in. centrifugal pump and was raised about 35 ft. and discharged through 400 ft. of 12-in. cast-iron pipe and some 200 ft. of 10-in. spiral-riveted pipe to the sludge lagoon.

After leaving the pumping station, the pipe is supported on posts at a distance from 10 to 6 ft. above the ground, and turns down just below surface level in the lagoon, where it discharges. The pipe was laid some five years ago, on a grade of 1 in 80, which it still retains, although, through the action of frost on the supporting posts, the alignment is not so good. Pump tests show that this grade is sufficient to carry the sludge away by gravity.

As the pipe ordinarily does not flow full, it was necessary to cause it to do so, and this was done by making a siphon at the discharge end, the height of which was a little greater than the loss of elevation due to the grade of the pipe.

For the purpose of the experiment, a length of 12-in. pipe south of the station was selected which was unaffected by either valves or bends. In fact, no obstruction to the flow occurred within 12 ft. of either end of this test length, which was 240.5 ft. long.

To measure the loss of head, two ¼-in. holes were drilled through the cast-iron pipe on its horizontal diameter, one at each end of the section selected, and, to insure the entrance being square and sharp, these holes were cut with a sharp drill running at high speed. The pipe was then counterbored half way through its wall and tapped to take a ¼-in. water pipe. At the north end, the ¼-in. pipe was turned down and then run horizontally to a point 6 in. north of the middle of the test length, while at the south end the pipe turned north and ran horizontally to 6 in. south of the middle. At this point, a mercury U-tube was inserted and connected to the ¼-in. pipe by rubber tubing. Quarter-inch gate valves controlled the pipe at the north and south ends

and ¼-in. pet-cocks at the center. The scales on the U-tube could be read to ⅛ in. and estimated to $\frac{1}{16}$ inch.

The volume of sludge was measured by a 12 x 6-in. venturi meter and register indicator recorder of the latest type. The indicator has a uniformly divided scale which can be read very accurately.

Before the experiment was started, the ¼-in. piping was carefully filled with clean water and all air was expelled; the watches of the two observers and the recorder clock were regulated as to time. Readings were taken at 5-min. intervals. At the end of an hour the observers changed places, and the experiments were continued for another hour. Some difficulty was experienced in reading the U-tube on account of the continual fluctuation of the mercury column, but the reading at the 5-min. interval was that recorded. The fluctuation was fairly uniform until a discharge of 4½ sec.-ft. was reached, below which it became very erratic. In consequence, these results were neglected. This was for two reasons: (1) On account of the small differential an error of ⅛ in. in the reading made a large percentage error, and (2) the flow had become turbulent due to choking in the sludge pump from heavy sludge and also the low discharge.

The value of n was determined by substituting in Kutter's formula for C and solving for n in each case. The results show a variation from 0.0168 to 0.0181, which is probably accounted for by variations in the density of the sludge. For comparison, the value of C in Hazen and Williams' formula was worked out on the slide rule. The results show that for Toronto conditions the addition of two years to the age of the pipe permits the Hazen and Williams' tables for water to be applied very closely.

Pint samples of sludge were taken every 10 min. at the discharge end of the pipe, and collected in a pail. At the end of the experiment, these were stirred thoroughly and a sample was taken for analysis.

The sludge analyzed as follows: Specific gravity, 1.01; moisture, 95.9%; solids, 4.1; percentage of dry solids which are volatile, 50.5; ash, 49.5%. The temperature of the sludge was 54° Fahrenheit.

The experiment was carried out under the general supervision of R. C. Harris, commissioner of works for the City of Toronto, G. G. Powell, deputy city engineer, and W. R. Worthington, assistant engineer in charge of sewers, and under the writer's immediate direction.

Structure and Strength of Overheated Rivet Steel

Failure of Long-Grip Rivets Led to Study of Overheating, Annealing and Forging—Microscopic Grain Structure and Strength Properties Investigated—Embrittling Effect of Overheating Made Clear

By S. H. Graf

Professor of Experimental Engineering, Oregon State Agricultural College, Corvallis

RECENTLY, in the construction of a steel building in Portland, Ore., it was necessary to rivet together a number of plates such that the thickness of the member thus built up was about 5 in., the rivets being thus rather long. The heads of some fifty of these rivets snapped off after cooling. It seemed that the manipulation had been little if any different from the usual practice, and the cause of this failure was therefore somewhat of a mystery. It was thought by some that the cause lay in inferior or defective material. A microscopic examination of the body as well as the field head of one of the failed rivets was made, and revealed in the body of the rivet the peculiar broken structure shown in Fig. 1. The head showed a very different structure, as shown by Fig. 2. Those familiar with work of this nature would recognize the structure in Fig. 1 to be that characteristic of badly overheated steel, while that in Fig. 2 more nearly represents the normal structure.

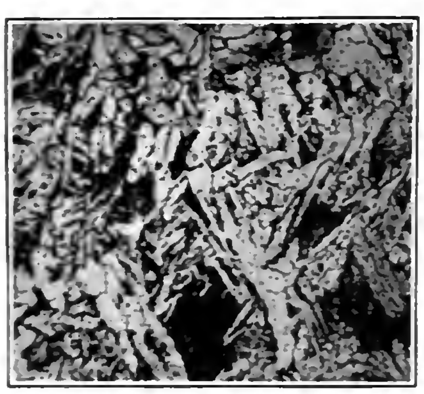

Fig. 1. Body rivet (x200)

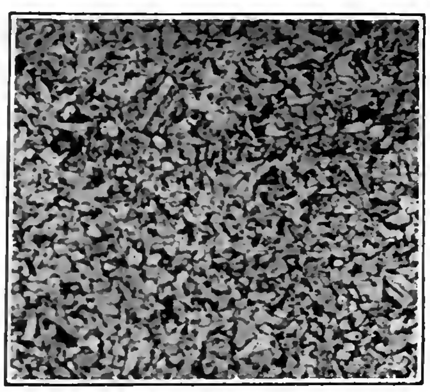

Fig. 2. Field head (x200)

STEEL STRUCTURE IN ONE OF THE RIVETS THAT FAILED

It is quite generally known that the overheating of steel causes a coarsening of its structure and a deterioration of its qualities. However, cases where this is of practical importance are uncommon enough to be interesting whenever they do occur.

To make conclusive the evidence of overheating as the cause of failure of the rivets in question, it was decided to conduct a little laboratory research, imitating conditions which might under different circumstances obtain in practice, and then to make studies of the steel structures and physical properties resulting from these various treatments. It was further desired in this study to determine, if possible, why, under most conditions, apparently no damage is done by a given treatment, while in other cases failure results from what is apparently the same mode of manipulation.

Rivet steels may contain from 0.05 to 0.25% carbon, according to the strength required. Ordinarily, the carbon content is in the neighborhood of 0.12%. For the purpose of the proposed microscopic tests, two ½-in. round bars were selected, differing in grade of steel, one containing 0.11 and the other 0.23% carbon. The first of these is similar in grade to the rivets which failed in the instance referred to, while the other represents rivets of the highest carbon content customarily used. Fig. 3 shows the normal structure of the first of these, and Fig. 8 that of the second.

Pieces of both of the test bars were subjected to the following manipulations:

(a) Held at 2100° F. for 10 min. and air-cooled.

(b) Heated in the forge until sparks began to be thrown off, and held at this temperature for two minutes.

(c) After treatment b (same specimens), refined by heating to the upper limit of the critical range plus 100° F. for 15 min. and air-cooled (1700° Fahrenheit).

(d) Using a fresh piece of the bar 2 in. long, treatment b, followed by upsetting the piece to one-half of its original length and forging out to about ¼ in. square.

Micrographs are shown in Figs. 4—7 and 9—13 of the results of these various treatments. All of these are to a magnification of 400 diameters, with the exception of Fig. 11, which is to only 100 diameters, the structure in Fig. 10 being so coarse that the entire photograph does not show one whole grain. The following table shows the grain size (in grains per square millimeter) resulting from the various treatments. The counts are necessarily only approximate in some cases, owing to the broken structure.

CHANGES IN GRAIN SIZE OF STEEL PRODUCED BY HEATING AND FORGING CONDITION AND TREATMENT OF STEEL

Carbon Content	Normal	(a)	(b)	(c)	(d)
0.11%	15,500	4,100	680	10,900	6,800
0.23%	7,100	3,200	168	17,500	12,400

These figures indicate quite startling changes. The soaking for ten minutes at 2100° F. has, in both cases, increased the grain size quite materially, and even the short heating at a sparkling temperature (about 2500° F.) has increased the grain size enormously, and in addition to this has considerably altered the character of the structure itself. Treatment c has resulted in a wonderful refining of the grain. In the case of the higher carbon content the grain is even finer than it was in the original steel. The forging treatment (see Figs. 7 and 13) has resulted in a very material grain refining, especially in the case

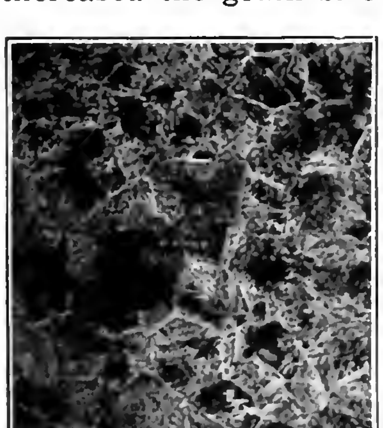

FIG. 11. STRUCTURE OF OVERHEATED STEEL OF 0.23% CARBON

Magnified 100 diameters (same as Fig. 10) but lower magnification used because structure is so coarse that Fig. 10 does not show an entire grain.

of the higher carbon content, where the grain has been rendered somewhat finer than it was originally.

Contrasting Figs. 5 and 10 with 7 and 13 shows why the structure in the head of a rivet may be normally fine, while that in the body (especially in a long rivet) may be extremely coarse. The head has been forged and thus refined. The body has simply cooled from a very high temperature, just as was the case here in treatment b. A thermal refining of the grain, as accomplished by treatment c, is of course not possible with rivets, but is practicable in the case of forgings, and is always applied to high-grade steel castings.

The micrographs already referred to show beautifully the changes in structure resulting from the different in structure far beyond the point reached by the specimens in these experiments, so that the ductility may be reduced to almost nothing. In the case of such long soaking, there may also be an absorption of carbon from the fuel in the forge, such as takes place in casehardening. This effect was looked for in the present study, but was very slight, if not entirely absent.

It is often thought—and the statement is sometimes made in case of a failure exhibiting a coarse crystalline structure—that the material has "crystallized" in service. The latest research has shown—at least in the case of ordinary low-carbon steels—that there is no such change of grain size, and that the coarse structure was there originally in the fabricated article, caused by some

EFFECT OF HEATING AND FORGING ON THE PHYSICAL PROPERTIES OF STEEL

TABLE I—REPEATED-STRESS TESTS

Condition	Alternations of Stress 1	2	Ave.
Normal bar	350	379	364
Overheated bar (treatment B)	183	61	122
Overheated and heat-treated bar (treatment C)	283	316	300
Overheated and forged bar (treatment D)	244	255	249

TABLE II—TENSILE TESTS

Condition	Yield Point Lb. per Sq.In.	Ult. Strength Lb. per Sq.In.	Ductility, %	Reduction of Area, %	Character of Fracture
Normal bar	45,600	65,100	31.5	72.2	Very fine silky
Overheated bar (treatment B)	70,700	71,400	4.0	10.8	Coarse crystalline
Overheated and heat-treated bar (treatment C)	47,800	66,200	17.5	55.8	Fine silky

treatments, but the question arises, Just what physical properties correspond to these different structures? In order to answer this question, repeated-stress tests were made on samples of $\frac{3}{8}$-in. rivet steel, in carbon content lying between the two steels which were studied microscopically. The tests were made by means of a Landgraf-Turner alternating impact testing machine; the results are given in Table I.

The alternating-impact test is quite a severe one, and yields comparative results which measure primarily the toughness of the material. An inspection of the results shows that the structure represented by treatment b and Figs. 5 and 10 is very brittle and unreliable. Either heat-treating or forging very largely restores the original qualities of the material so far as toughness is concerned.

Tensile tests were made in a 50,000-lb. Riehlé testing machine on the same material as used for the repeated-stress tests. The results were as given in Table II.

These tests show quite conclusively what happens. In the overheated specimen the yield-point is raised so high that it closely approaches the ultimate strength. The ductility and reduction of area are reduced to a small fraction of what they are normally. The coarse crystalline nature of the structure is also in evidence. The heat-treating greatly improves the material, bringing it back nearly to its original good quality. The very low ductility in the case of the overheated specimen shows why rivet heads may snap off when such material cools from a high heat to atmospheric temperature. The contraction on cooling under these conditions, especially with long rivets, is sufficient to stress the rivets beyond the elastic limit of the material, so that if the ductility of the metal is much reduced the rivets will actually be pulled in two by the contraction.

It must be understood, too, that rivets allowed to soak in a forge for a considerable time may be coarsened error or accident in manipulation either in the production of the steel or in its subsequent treatment.

In conclusion, it may be said that this study of rivet steels shows clearly the danger of overheating rivets (and steel generally), either by holding at a very high temperature for a short time or by long soaking even at temperatures ordinarily considered safe.

Shipbuilders Encouraged to Think at McDougall-Duluth Yard

Two new features have been introduced in the McDougall-Duluth Co.'s shipyard, Duluth, Minn., to increase coöperation between the men and the management. Most novel of the two is an Invention Division, which the yard monthly, the *Riverside Review*, says has just been established by the company to give legal and technical assistance to any employee of the company who may have an idea worth patenting. S. G. Stevens, patent attorney of Duluth, has been retained to give advice.

Any employee can obtain Mr. Stevens' assistance through the industrial department of the shipyard. The service is intended to assist in (1) developing an idea to the form of a patentable invention; (2) comparing it with prior patents that conflict or that may be helpful, and (3) bringing out its commercial possibilities. A plan for financial assistance in developing and patenting inventions for its employees is under consideration by the company.

Revival of the suggestion box is another means by which the company aims to enlist the coöperation of the yard workers. The box was established more than a year ago, in the early days of the yard, but during the building and great expansion of the new plant it ceased to exist. Now A. Miller McDougall, general manager, has reëstablished the suggestion box and will take personal supervision of it.

Keeping Economy of Operation Paramount in a Shipyard Layout

Despite Cramped Quarters Moore Plant on San Francisco Bay Adhered to Standards for "After-the-War" Basis—Ways Served by Derrick Towers—Transportation on Zone System—Ordering Methods

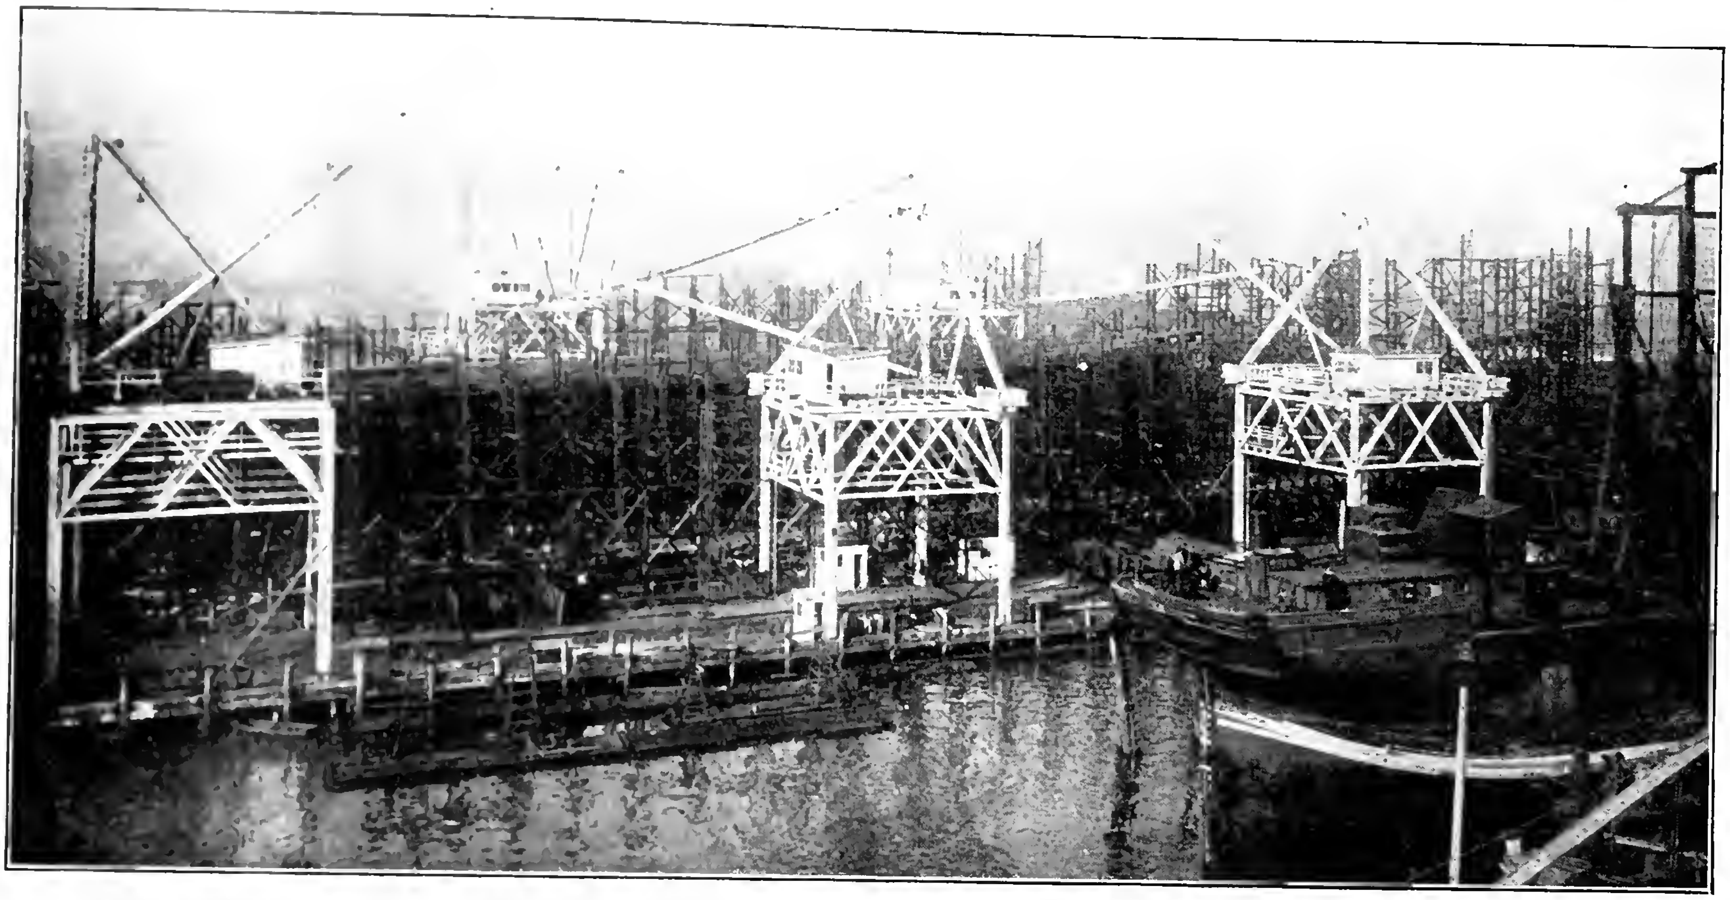

FIG. 1. MOORE SHIPYARD USED DERRICK TOWERS INSTEAD OF TRAVELING CRANES FOR BERTH SERVICE
Material is delivered to wide storage spaces alongside the ways by locomotive cranes. The latest derrick towers are 70 feet high.

LIMITATION of yard space at the Moore shipyard on San Francisco Bay called for careful attention to layout, in order that material could be handled economically. Studies of the material-handling methods were continued while the yard was in operation, and as it expanded improvements in the system continued to be made. By the time the plant had grown from two ways to ten, there had been developed the slogan of "economy of operation on after-the-war basis," and efforts were consistently directed toward adhering to that standard. Expansion on both sides of the original plant and the fortunate selection of main building sites for the early development are factors without which this would have been impossible.

Important steps in attaining the desired economy of operation are the zoning of locomotive-crane travel and the card-index and requisition systems used for recording and ordering out plates and shapes. There has been constant effort to avoid interference in delivery and fabrication and to find storage space, particularly along the ways, where material ready for the boat could be located most conveniently. Elbow room in the fabrication yard has been insisted upon, and continual attention is given to plate-shop organization.

It is also notable that because of the delays and difficulty attendant upon getting delivery from Eastern factories some of the shop equipment and several cranes were designed and built in San Francisco.

The machines in the angle yard are set up under "umbrellas" consisting of four piles supporting a central roof and four radial jib cranes. The booms of these cranes are I-beams hinged to the four corner piles; they constitute an important feature in time-saving in the angle yard. The booms carry differential chain blocks and a workman can swing the boom by one hand with the same movement that draws the block along to the desired point. These "umbrellas," developed in the San Francisco Bay region, illustrate the simplicity of device and economy of construction notable in many of the Western yards. Their open construction indicates how the climatic advantage favors this region as a shipyard location. In winter or summer the slight shelter afforded by the umbrella is sufficient protection for the workmen

Raw Steel Card-Indexed—The angle yard is laid out to handle steel shapes up to 80 ft. long, weighing 20 lb. per foot. Here, as well as in the plate yard, materials are classified for storage according to size; there is no attempt to segregate material for any particular hull. Coupled with this plan is a card-index system whereby each piece of steel, as it is received from the mill, is recorded on a card. The card (Fig. 4) has a space for the mark by which the piece has been ordered, the number of the hull for which it is intended, the size and thickness of the piece, the date received into the yard and the number of the order under which it goes out of the yard to the shipfitters. There is also a space for entering the sheet number in the list of material which is kept separately for each hull. By the use of this system it is possible to draw material for any hull

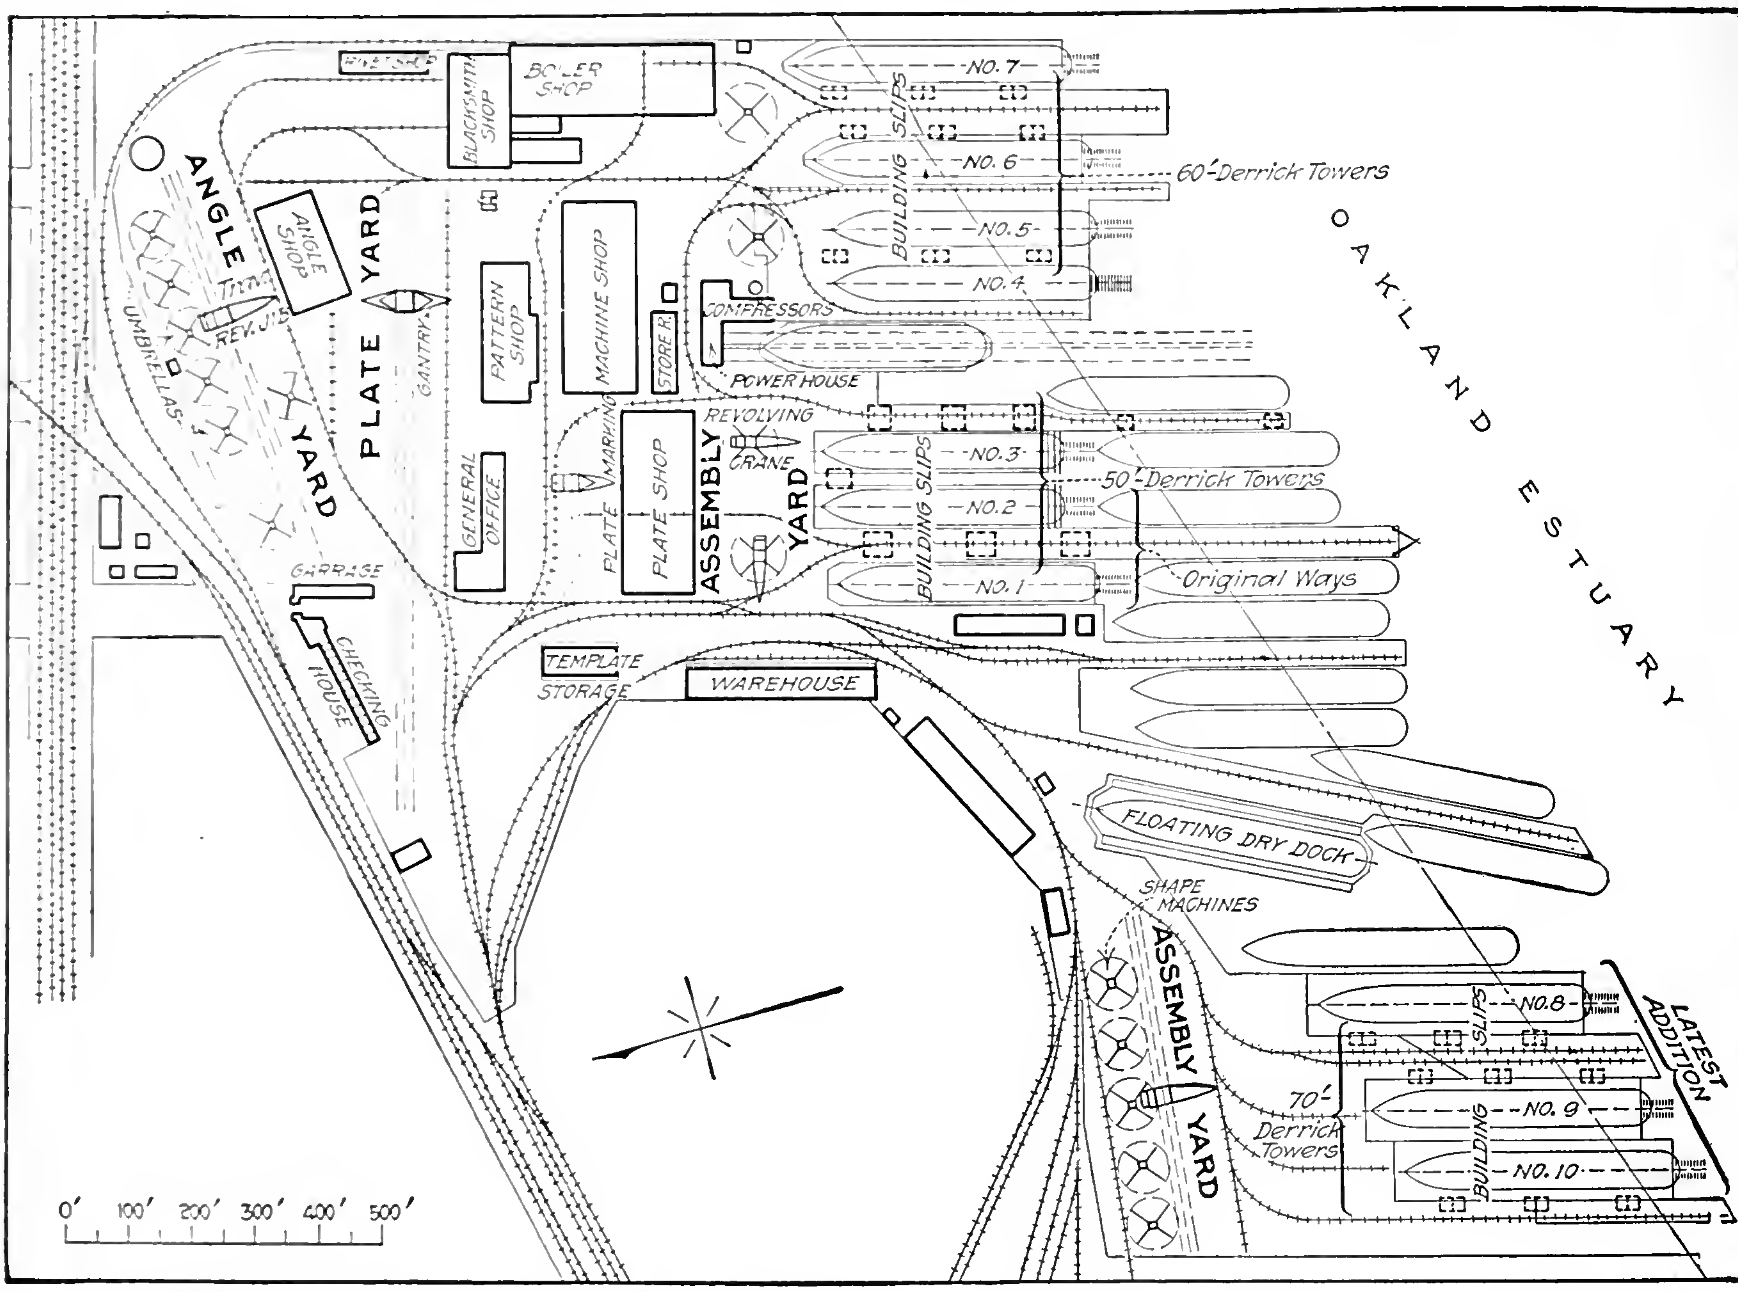

FIG. 2. SPACE LIMITATIONS RESPONSIBLE FOR IRREGULAR PLAN OF SHIPBUILDING AND DOCK COMPANY'S YARD

from the general stock supply without complicating the records, and yet there is convenient record of how such material was used.

The angle shop has equipment for cold and hot bending of angles and shapes, including two 9-burner 50-ft. oil furnaces for heating the longer pieces. Realizing that bent shapes are the greatest source of trouble in the erection of vessels, particular attention was devoted to the equipment of the angle shop, and careful study has been given to its arrangement and method of operation.

Yard Crane Equipment—Cranes for service over the material yards were not to be had in time from Eastern plants; therefore, three traveling cranes with revolving booms and two stationary revolving cranes were built to special design, and a cantilever gantry (Fig. 3) for the plate-storage yard was rebuilt from material already on hand in the old yard. Each of the revolving cranes has a 90-ft. counterbalanced boom, and as auxiliaries four jib cranes, one on each corner of the main tower. The jib cranes, hinged to swing through an angle of about 150 deg., are found exceedingly useful, particularly on the stationary cranes in the fabrication yard. (See view, Fig. 7.) Eight locomotive cranes are used at the Moore plant, seven 15-ton and one of smaller capacity. Because of the long haul from end to end of the trackage, it has been found economical to limit the travel of cranes to certain zones; that is, to each crane is assigned a section of the trackage beyond which it does not operate except under special orders. Under this plan loss of time in rehandling from crane to crane is actually very little, cer-

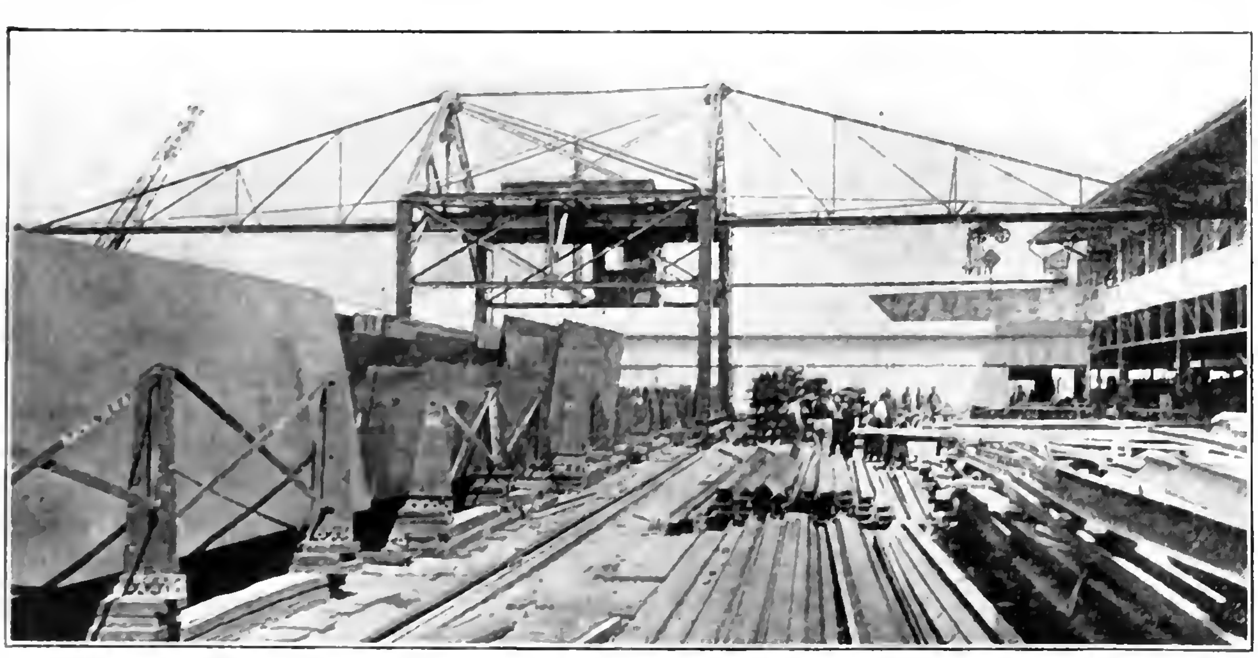

FIG. 3 CANTILEVER GANTRY IN PLATE YARD WAS BUILT FROM MATERIAL ON HAND

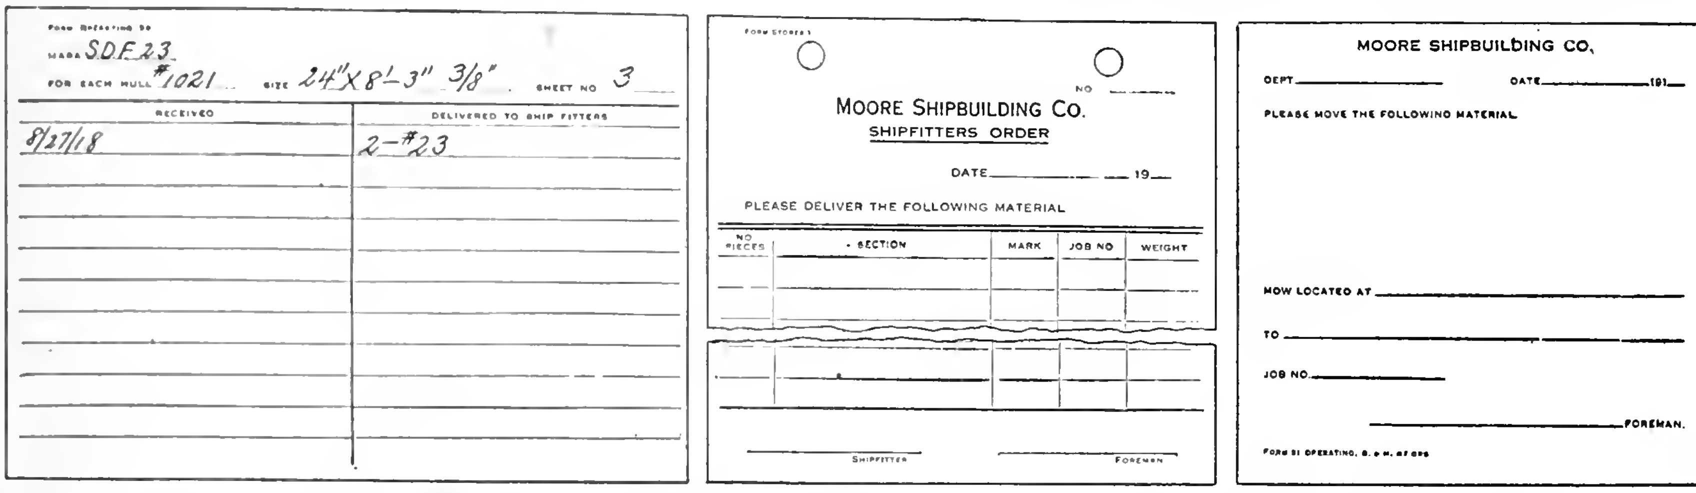
tainly much less than that resulting from waiting for right-of-way past a crane in another zone. The plan has been made most effective by endeavoring to select as far as possible zones which are between natural terminals—as from plate storage to assembly yard, or between any other two points where rehandling would ordinarily be required. The time of the locomotive cranes has been still further conserved by the use of eight one-ton Ford tractors which reach all parts of the yard and the storage along the ways. These handle all small material and relieve the locomotive crane of many minor errands.

Ordering Material and Transportation—Material is taken from the storage yards on a "shipfitters' order," signed by the shipfitter and the foreman, Fig. 5. This order indicates the number of pieces and the exact kind of material required, and gives the number of the hull on which it is to go. The locomotive-crane foremen turn these slips in daily to the material superintendent's office. From them, together with the checked invoices on incoming freight, the stock records are kept up to date. Shapes and plates are recorded in separate card indexes, the cards being filed alphabetically by "mark," which is the designation by letter and number on each material shipment received.

A very simple plan which has saved much time and confusion in this yard is the scheme of using a foreman's requisition for ordering material moved for a special purpose. Formerly, it was necessary to find the superintendent of the material-handling department or one of his assistants and get permission to have a locomotive crane do the special moving job. This is now unnecessary; all foremen are authorized to fill out and sign a special form, about 4 in. square, which, when presented to the nearest craneman, authorizes him to move the specified material as requested. On this form, Fig. 6, there are filled in the date, the description, the present location and the destination of the material, and the number of the hull for which it is needed. These slips, turned in daily by the locomotive-crane men, give a check on the time and the hull number to which the special service should be charged.

Derricks Serve Ways—The ways are served by derricks on stationary wood towers. On the first ways these were made 50 ft. high, on later ways a 60-ft. height became standard and finally, in order that troop ships could be served easily, new ways were equipped with 70-ft. derrick towers. By using stationary derricks with long booms the maximum of undisturbed storage was made available in the limited space between ways. The ways in the original plant had two derricks per tower with three towers between ways. In later additions the plan has been changed to single-derrick stationary towers, three to each way. The towers are of wood. The booms are 105 ft. long and can place 12½ tons at a 65-ft. radius, which is enough to reach beyond the center of the ship.

An assembly or fabrication yard at the head of the slips is used for building up heavy work such as transverse units, pillars, hatch girders, etc. This yard, shown by the view, Fig. 7, is served by two 3-ton revolving cranes which deliver to the derricks at the forward ends of the ways or to flat-cars for the derricks farther down the ways. Near the three new ways in the far end of the yard a storage space is provided for finished shapes and plates. From this storage a traveling crane with a revolving boom will deliver the material to flat-cars, from which it will go to the storage alongside the way. The policy is to keep the storage along the ways always as near capacity as possible. As soon as the final plates for the ship have been taken from one section of the pier storage, material for the next boat is assigned to that space. As the first boat nears completion as much material as possible is stored on the pier for the one that is to follow.



FIGS. 4, 5 and 6. MATERIAL INDEX CARD, WAY ORDER, AND TRANSPORTATION ORDER FORMS

Fig. 4. Each piece of steel received is recorded on a card like this, the cards being filed according to the piece mark. Fig. 5. This form with two signatures is needed to authorize delivery of material from storage yard. Fig. 6. Foremen get locomotive crane service with this order; the order slip system avoids verbal requests and allocates charges for crane time.

In the plate shop, as in those of other Pacific Coast yards, there is a notable absence of multiple punches or other heavy equipment which could have come only from Eastern factories. Nevertheless, material is put through at high speed. The plate shop and the angle shop in this yard, with a total area of about 50,000 sq.ft., average almost 12,000 tons of finished metal per month.

The Moore plant has installed its own rivet shop, so as to have an independent rivet supply. The bars for making the rivets are always available from the coast mills. Much of the steel for this yard comes from the Gary plant of the Illinois Steel Co., although shapes and bars are frequently allotted from the San Francisco and Seattle mills of the Pacific Coast Steel Company.

The cost-plus contract under which this yard operated at first has been revoked to put the yard on a lump-sum basis. The latter, with provision for protecting the yard on advances in materials or labor cost, is con-

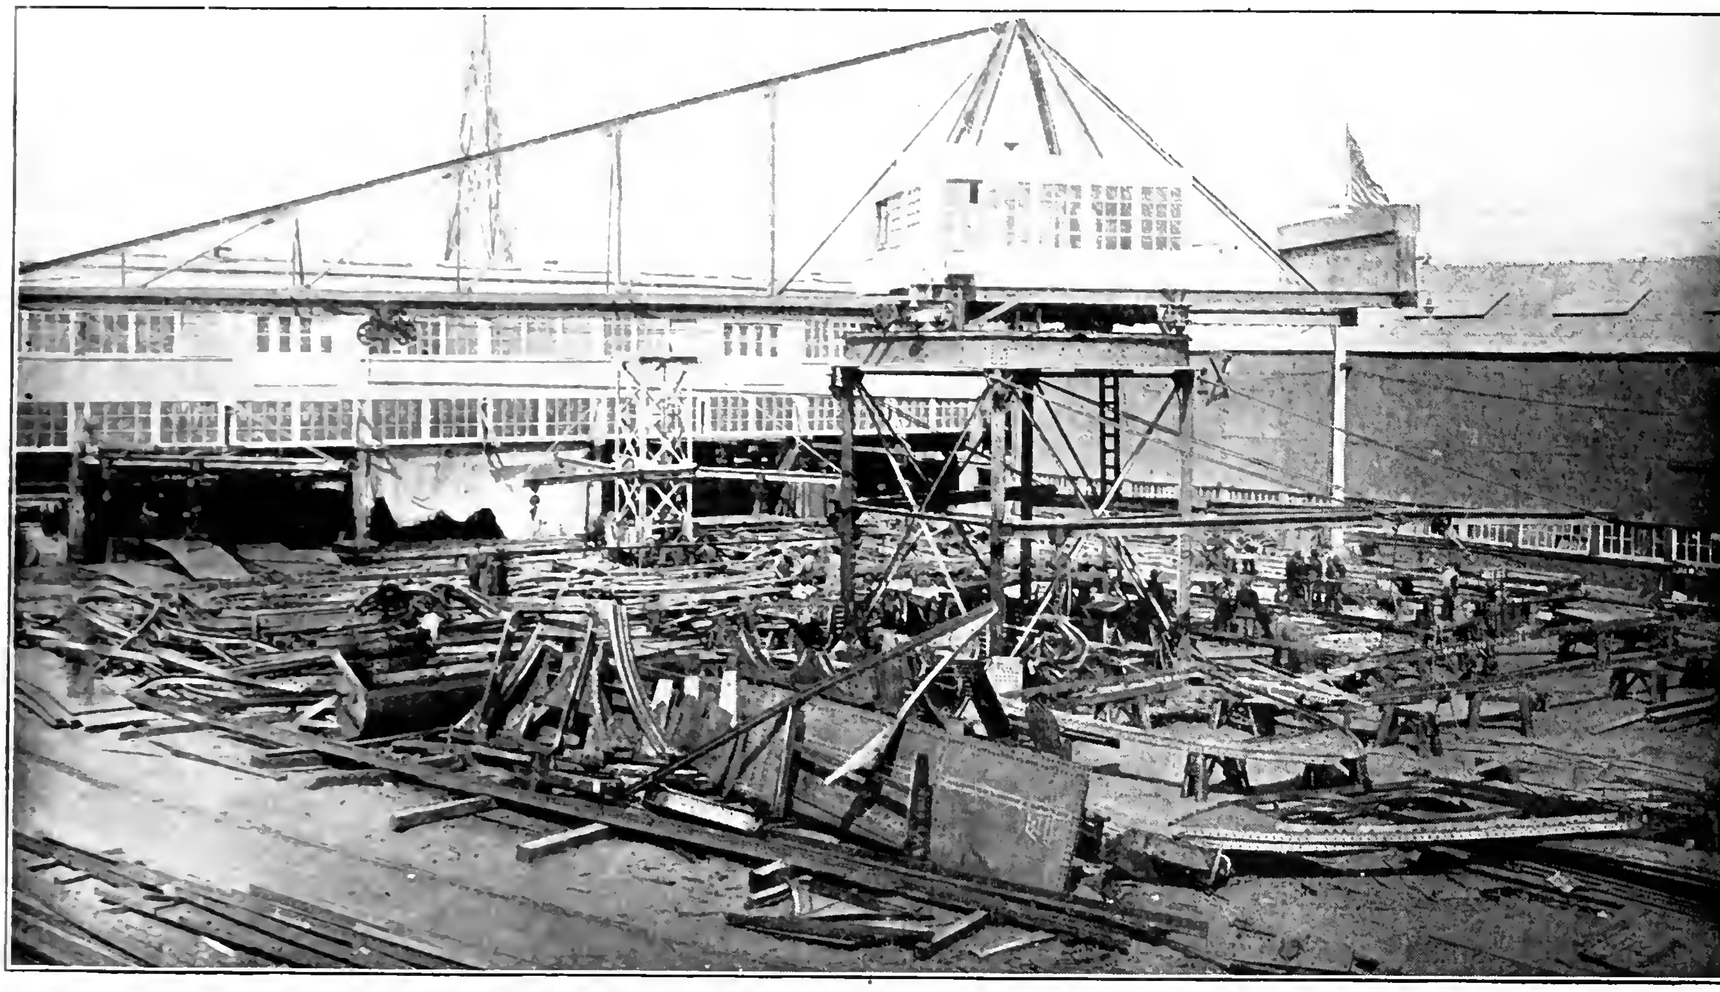


FIG. 7. ASSEMBLY YARD AT HEAD OF WAYS, LOOKING TOWARD PLATE SHOP
The crane is one of the home-made revolving cranes which do much of the yard service at the Moore plant

sidered much more satisfactory. At present the yard is working on 9400-ton refrigerator boats; after their completion twelve 10,000-ton tankers are to be built. The plant employs about 8000 men in all three shifts.

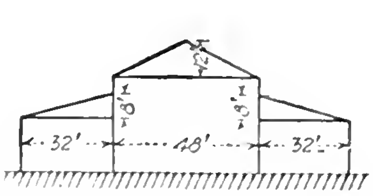
George A. Armes is president and general manager of the Moore Shipbuilding Co., Andrew Moore is first vice-president, and J. A. Moore is second vice-president and general superintendent. Leland S. Rosener, consulting engineer, has laid out the extensions and has designed cranes and other equipment that were built locally.

How Define the Pitch of a Roof?

By R. Fleming
American Bridge Co., New York

The pitch of a roof is defined, in many a dictionary, handbook and textbook, as the proportion obtained by dividing the height by the span. In most dictionaries of the English language the term is classified as architectural, and the definition is often followed by an explanatory note such as, "If the rafters exceed in length the width of the building the roof is said to be of the Elizabethan or knife-edge pitch; if they are equal to the width the pitch is Gothic; or if two-thirds the width the roof is said to be of a true pitch, or of the Roman pitch; a roof still flatter than this is the Grecian pitch."

The definition is at once seen to be ambiguous in the case of a lean-to or shed roof. If the pitch of the roof over the center aisle is $\frac{1}{4}$, what is the pitch of the roofs over the side aisles, in the accompanying diagram? The inclination of the rafter with the horizontal is sometimes expressed in degrees. But for ordinary slopes this method is cumbersome—a rise of 6 in. to the foot indicates an angle of 26° 33′ 54″. Again, the pitch has been interpreted as the quotient of the rise divided by one-half the span. This is at variance with the commonly accepted definition, but has the same ambiguity. The writer is of the opinion that the term "slope" should be adopted in structural engineering, and suggests the following definition: The slope of a roof is the natural tangent of the inclination with the horizontal, and is best expressed in inches of rise to one horizontal foot. There is no ambiguity in the definition, and the slope is easy to lay out. The mental gymnastics necessary to interpret such sentences as, "the pitch for tar and gravel roofs shall preferably be from $\frac{1}{32}$ to $\frac{1}{24}$," would be avoided. A specified slope of $\frac{3}{4}$ in. to 1 in. per foot would convey at once a picture of what was intended.



TYPICAL ROOF OUTLINE WITH DIMENSIONS

Suggestions and Complaints in Railroad Operation

According to the annual report of Director General W. G. McAdoo, the Bureau of Suggestions and Complaints of the Railroad Administration, established Sept. 3, 1918, received in all 10,424 "initiatory letters" containing 11,666 suggestions, complaints, and commendations. Those commending employees for courtesy and loyalty exceeded the complaints of discourtesy by nearly two to one. In all, some 1328 communications were received, as against 714 letters complaining of individual discourtesy or incompetence. The commendations received have been noted upon the records of the employees and will receive due consideration. In addition, 128 communications commended the railway service rendered by particular lines.

Baltimore Garbage Will Be Made Into Pork

Contractor Will Pay City Three and a Half Times as Much Per Ton as Chicago Top Price for Market Hogs, Thus Eliminating Gambling Risk to Both Parties—Change from Disposal by Reduction

BY WALTER E. LEE
Water Engineer of Baltimore, Md.

A FEEDING contract for the disposal of garbage was awarded by the City of Baltimore on Dec. 21, 1918, for a period commencing May 1, 1919, and ending Dec. 31, 1923. Under it the contractor will pay the city an annual estimated sum of $31,500. Barging and towing costs will reduce this by $15,000, leaving an annual net return of $16,500.

The writer, in a report of Jan. 28, 1918, to Mayor James H. Preston, recommended that garbage be disposed of by reduction in one central plant; ashes by filling ravines, low marshes and swampy ground along the water front for reclamation of land; and rubbish by incineration of the combustible portions, except the recoverable merchantable articles, in three municipal incinerators. (See *Engineering News-Record* of Mar. 14, 1918, p. 522.)

The history of garbage disposal in Baltimore has been, successively, dumping on the ground, reduction and, finally, feeding. From 1882 until 1901 the garbage was barged to a point six miles below the city by a contractor and there spread over the ground as a farm fertilizer.

A contract for 10 years was awarded, commencing Oct. 20, 1902, at an annual payment to the contractor of $147,300, for the collection, removal and disposal of garbage. An Arnold-Edgerton reduction plant was erected in the heart of the city near the water front, to which the collection carts of the contractor made a direct haul. Complaints of the noncollection of refuse became so numerous, and objections to the odors from the reduction plant were so strong, that the city terminated the contract on Jan. 1, 1908, purchased the collection equipment and reduction plant from the contractor for $372,888, and placed directly under the Commissioner of Street Cleaning the collection and removal of garbage from residences.

A second reduction contract was awarded in 1908 for 10 years, terminating Dec. 31, 1917, at an annual payment to the contractor of approximately $75,000. A new company was organized, and the reduction machinery was leased from the city at an annual rental of $10,000. At the expiration of this contract it was extended for a period of one year, until Dec. 31, 1918, at the request of the city. Under this extension no rental was paid for the use of the city's machinery, so that the cost of disposal amounted in effect to $85,000.

FIRST OF THREE CALLS FOR BIDS IN 1918

The first specifications for disposal by reduction, in furtherance of the recommendation of Jan. 28, were advertised in March, and bids were opened Apr. 17, 1918. Proposals were asked on the basis of a lump sum yearly payment to the city under an 11-year contract, the city to deliver to the contractor all garbage produced within the city.

The specifications defined garbage as being every accumulation of animal, fruit or vegetable food waste, containing not more than 5% by weight of other refuse, generated by or resulting from the decay, deterioration, storage, preparation or handling of animal or vegetable matter in any place or at any point where food is prepared for human consumption, including all kitchen and dining-room refuse.

The contractor was required to receive the garbage at the water-front dumping stations provided by the city, and convey it on his own scows and by his own power to the site of the reduction plant.

The specifications provided that the garbage should be handled and disposed of under a "closed" system of reduction, so as to prevent the emission of offensive odors of any kind while being handled, treated or reduced, and that the process, machinery and apparatus be thoroughly sanitary in effect and the plant so conducted as not to cause conditions which would be detrimental to the public health or comfort, or in any way constitute a public nuisance. All gases carrying odors which were produced or resulted from the operation of the process, machinery or equipment used were to be confined and, before being liberated to the atmosphere, were to be thoroughly deodorized. All water flowing from the plant was to be inoffensive, free from nuisance or any matter dangerous to the public health or to the oyster beds in Chesapeake Bay or its tributaries. It was further specified that the city should have the option of purchasing the plant and equipment from the contractor at the expiration of the contract, and that the reduction site should contain not less than five acres, situated on at least one railroad or above high tide on a navigable waterway.

Under this specification a flat offer of 35c. per ton was received from a bidder who proposed to employ the Cobwell process of reduction, but the city failed to secure the approval of the Capital Issues Committee for the necessary stock issue for the erection of a plant of a capacity of 350 tons per day, and the bid was subsequently released.

A second specification was advertised on Oct. 2, with bids to be opened Oct. 16, 1918, under which the city obligated itself to do the same things as in the previous specifications and asked for alternate proposals on disposal by reduction or by feeding. The reduction contract proposed was for 16 years and offered to the prospective bidders, without charge, the use of machinery which the city owned in the existing plant, for reërection and operation in a temporary plant until the end of the war, after which a permanent plant was to be erected. The contract for feeding was for five years. No bids were received under either plan.

A third specification was advertised on Dec. 6, and bids were opened Dec. 18, 1918. Under this specification the city undertook the delivery of garbage from the water-front stations to the contractor's disposal

site, as the city realized that the collection and removal of garbage from its water-front dumping stations was simply an extension of the collection and removal from the residences, and a matter in which the contractor has no primary interest. The towing of garbage was a proper function for the city to undertake, for when any contractor is required to undertake it the public at large is not always satisfied with the way in which the work is done; but when it is done by the city the public always has the proper remedy for getting a quick and adequate response to its complaints of the accumulation and nonremoval of garbage from the water-front stations.

An act of the Maryland legislature prohibits the erection of a garbage-reduction plant within a nine-mile radius of Lazaretto Light, a shore light in Baltimore harbor, and consequently any possible site for such a plant would involve a barging distance of 16 miles from the water-front dumping station in the city and four hours of towing either way.

Alternate proposals were again asked on disposal by reduction or by feeding. The term for reduction was 16 years, and a flat price per ton was requested—with an adjustment, to be stated by the bidder, in cents per ton for every upward or downward fluctuation in the market value of grease from a basic price of 8c. per pound, as the city felt that it should share this risk with the contractor so that all elements of gambling in making a bid should be entirely removed. The term for feeding was five years, commencing May 1, 1919, and bids were requested on an annual flat payment to the city for each ton of garbage delivered to the feeding site.

No bids were received for reduction, and only one bid for feeding. The contractor operating the present reduction plant made no formal offer.

A contract was awarded Dec. 21, 1918, for disposal by feeding. The price to be paid to the city for each ton of garbage delivered is 3½ times the price per pound of live killing hogs on the Chicago market, as determined by averaging the top prices for each month. The scales for weighing the garbage are located at the feeding site, and all garbage is drained before weighing.

Until May 1, 1919, at which time the piggery shall take the full quantity of garbage produced, the city with its own forces will temporarily dispose of its garbage by burying it in shallow trenches 18 in. deep and 5 ft. wide, in which the garbage is placed 12 in. thick and covered with 6 in. of sandy soil. There will be 17,000 lin.ft. required to accommodate this temporary disposal of garbage. The cost of the temporary disposal is 85c. per ton against a former cost of $1.06 per ton under reduction, the towing cost being included in both figures.

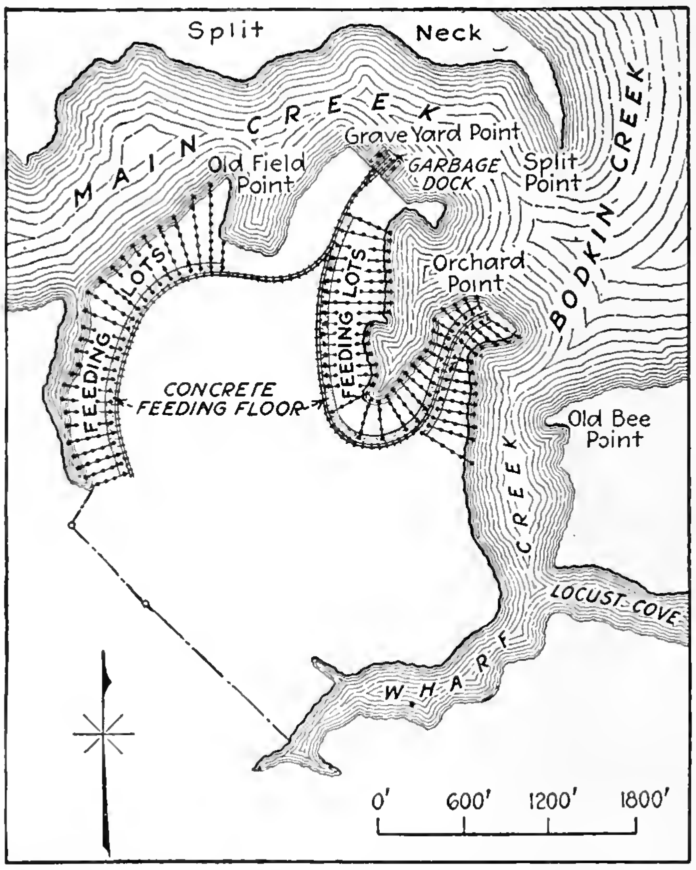
City Delivers Garbage to Feeding Plant

The contractor pays for all household garbage delivered and for those portions of market refuse derived from an animal source, but not for that from a vegetable source or for any packing-house refuse.

The city obligates itself to enforce good primary separation and to deliver the garbage in as fresh a condition as possible to the feeding site, with not less than four deliveries per week in summer and three deliveries per week in winter.

The contractor is given the privilege of using the empty city scows, without charge, on their return trip to the city, for the transportation of the products of the piggery.

The 160-acre farm on which the feeding operations will be conducted is almost level and has sandy soil, insuring good drainage with considerable water through an extensive shore line. Scrub-pine, chestnut and oak timber affords protection from the summer heat. The farm is owned by the city and was purchased at an average price of $140 per acre. It is situated on a point on the opposite side of the tributary of the Chesapeake Bay on which the existing garbage-reduction plant is



FROM SCOWS GARBAGE WILL BE DELIVERED BY SHORT RAILWAY TO CONCRETE FEEDING FLOOR

situated, and this proximity to a plant which has been operating 11 years without any formal complaint or restraint will insure a like freedom for the piggery.

The specifications require that the piggery shall be operated subject to the general and local public laws and under the supervision of such veterinarian and sanitary officers of the county and state as have proper jurisdiction. The city will also employ a veterinarian who will have continual supervision and inspection over the work of the piggery. The garbage which is unfit for feeding or not consumed shall be removed from the feeding platforms, which shall be cleaned at least once a day, and shall be disposed of by the contractor through sale or by plowing under the soil.

The area of Baltimore is 80.5 square miles and the estimated population, with the recently annexed territory, is 720,000. The quantity of garbage produced and the seasonal fluctuation are shown in the accompanying tables. (See the following page.)

It is estimated that 15,000 hogs will be required to consume the maximum amount of garbage that is produced during the summer peak; this will probably rep-

TABLE I.—YEARLY COLLECTION OF GARBAGE AND DEAD ANIMALS, IN TONS, AT BALTIMORE, MD., 1908 TO 1918

Year	Garbage Production, Tons	Number of Dead Animals	Estimated Population

*Estimated from eleven months' collection.

resent the largest piggery in the world, and Baltimore will be the largest city of the United States which has adopted this method for its disposal of garbage. Young shoats, vaccinated with cholera serum, will be purchased in the open market and shipped to the feeding station, where approximately 100 animals will be placed in feeding lots 70 x 250 ft. in area.

Garbage will be unloaded from the city's scows at the feeding site by the contractor, by the use of a locomotive crane with a 1-yd. grab bucket. The garbage will be dropped into steel rocker double-side dump cars of 10-yd. capacity, each on an adjacent track, and hauled by an oil-burning locomotive directly down a lane between the feeding lots, as shown by the accompanying map.

The end of the feeding lots adjacent to the railroad will have a monolithic concrete feeding floor, from which the animals will be excluded by wide gates when the garbage is being dumped from the rocker side-dump cars.

When the train has traveled to the full length of its trip, the garbage will be spread on the return trip to the wharf by a spreader from the rear end of the train, after which the gates will be opened and each lot of hogs allowed to enter on the concrete feeding floors.

Disposal of garbage by feeding involves a relatively small capital investment, which can be quickly and almost wholly liquidated at the expiration of the contract, and in this respect differs from all other garbage reduction plants, in which the machinery is of little use for any other purpose and possesses only a scrap value.

Feeding is a reliable method, and one which offers the highest financial returns to a municipality. It is absolutely essential, however, that the responsibility of the bidder be determined beyond the shadow of a doubt, which condition is usually met when there is sufficient training in animal husbandry and practical experience by the bidder in piggeries that have previously been managed successfully.

Road Building Materials Supply Solved by System

Wisconsin County Eliminates Delays and Demurrage—Contractors Selected for Past Record—Cost-Plus-Profit Contract

By Walter J. Driscoll
Assistant Commissioner of Highways, Outagamie County, Wisconsin

Sand, stone and cement are delivered f.o.b. cars at the nearest railway station to all contractors for concrete road work in Outagamie County, Wisconsin. This system has helped greatly in expediting the work, but, to make sure of efficient handling of the contracts, the county highway commission selects the contractors only after careful consideration of their past performances, instead of accepting the lowest bid. Coupled with a special contract insuring a definite profit to the contractors, this arrangement has simplified the war-time difficulties of road construction and assured steady progress in the county's road-construction program. In fact, since the plan has been in operation there has not been a single delay of moment due to nondelivery of materials, and the season's output of finished road has been increased one-half.

Present Outagamie County road practice has developed by steps. The first was education of the citizens to the need of spending money for improved roads. Then, a season's work was undertaken under the old-style itemized-bid contract awarded to the lowest bidder, and the operation of the plan was studied. Revision of the plan to that outlined above was the outcome of this study. Trial of the new plan proved satisfactory, and

IMPORTANT NOTICE. MAKE GOOD CLEAR FIGURES. Foreman should fill out this card very accurately and carefully and nightly must put all cards of the cars unloaded this day in envelopes and nightly mail to the office of the County Highway Commissioner, Court House, Appleton Wis. Failure to properly send in records of each and every car unloaded daily, will result in a Penalty of $1.00 assessed against the man neglecting to render such report

DEALER'S SHIPPING AND FOREMAN'S UNLOADING REPORT CARDS

its details were improved until the practice described hereinafter was adopted.

Outagamie County is the first in the State of Wisconsin in which a proposition to issue bonds for road construction has been carried by popular vote. Ordinarily, the bond issues throughout the state have been small and have been made by action of the county boards. The electors of Outagamie County in the spring of 1916 approved a bond issue of $700,000 for the construction of a county system of concrete highways. More than 60 miles of these roads have been completed at the present time, and so pleased are the people with the results that in the autumn of 1917 an additional bond issue of $272,000 was voted further to extend and complete the system.

During the first season, little actual construction was accomplished. Contracts were let to the lowest bidder, the only requirement being that the contractor must be able to obtain a sufficient and approved bond. By this contract, also, the contractors themselves furnished all construction materials. Actual construction was begun about July 1, and the next thing realized was that it was Oct. 1 and little of the road had been completed. A few of the contractors had done fairly well while some had failed miserably. The result was that some of the main trunk highways were blocked during the winter, and the people began to evince dissatisfaction.

Partial failure of the first season's program prompted reflection, and the winter of 1916-17 was devoted to study of possible reforms. One conclusion appeared inevitable—a radical departure in plan from the usual methods of road construction in Wisconsin was necessary. It was decided that the county must and would exercise a more rigid choice in the selection of contractors who were to carry on future road work, and would also abolish the practice whereby the low bid was the sole basis on which contracts were awarded. Nothing promotes general satisfaction with and creates a favorable sentiment toward road improvement like the execution of a contract in a minimum length of time. Nothing arouses greater dissatisfaction than to have one of the main roads of a community closed to travel for a long period. Consequently, it was decided to confine future business to contractors who had demonstrated their ability to execute their contracts systematically, and who were equipped to execute their work successfully and in the shortest practicable time. The execution of this plan called for a new form of contract.

Contractor Assured of Reasonable Profit

Assurance to the contractor of a reasonable profit was the basis of the contract adopted. All equipment is provided by the contractor, and he gives the work his personal direction for a fixed sum per mile. Labor is hired and paid directly by the contractor, who is reimbursed twice a month by the county. Time is kept by the county inspector. Also, the county commissioner has power to set the maximum wages and to discharge unfit or incompetent workmen.

Attached to and forming a part of the contract is a preliminary estimate by the county commissioner of the labor cost. If the contractor keeps the actual cost below the estimated cost he receives a percentage of the saving. Also, if he permits the actual cost to exceed the estimated cost he pays a percentage of the excess. Both bonus credits and penalty charges are on a sliding scale, so fixed that the contractor's bonus or penalty increases as the saving or the loss increases. The contract for a county road known as the Seymour South highway illustrates the sliding-scale arrangement. Labor cost per mile was estimated at $4298. Below this sum, to $3998 per mile, the contractor's bonus was 20% of the decrease; below $3998 to $3700 it was 40%, and below, $3700 it was 50%. If the cost increased over $4298, the contractor paid 20% of the increase to $4598; 40% of the increase from $4598 to $4896, and 50% of all increase above $4896.

Besides paying all labor costs, the county purchases and delivers all construction materials to the nearest railway station. Experience with the first season's contracts indicated that delay in the supply of materials had been a prime cause of hindrance. All materials had to be shipped in by railway from plants and quarries situated from 50 to 100 miles from the work. Certain contractors seemed able to obtain materials—at times even more than they required to meet current consumption—and would accumulate stocks, while other important jobs would be shut down for lack of one kind or all kinds of materials. For example, important jobs on the outskirts of the City of Appleton, which is the county seat, were tied up for lack of material, while less essential roads, from the standpoint of service to the whole county, were receiving more material than was needed to maintain progress. Coördination of materials supply, considering the road work as a whole, was lacking. Obviously, the remedy was to be found in selecting a single head who would direct and control the supply and distribution of materials for all the road work of the county. Naturally, the most appropriate head was the county road commissioner.

OUTAGAMIE COUNTY HIGHWAY COMMISSION

CEMENT CARS RECORD

Name of Road ____________ Date ____________

Contractor ____________

We hereby report that this day we have received and unloaded the following cars of cement, consigned to Outagamie County.

Car No.	Initial	No. of Bbls.

Signed ____________

IMPORTANT NOTE. Contractors must mail in these cards **nightly** of the day cars are unloaded. Failure to receive these cards promptly results in the loss to the County of discount for prompt payment from the Cement Companies, so therefore discount losses to the County, through Contractors failure to nightly fill in and return the correct car records, will be charged against said contractor or dealer and deducted from his contract.

CONTRACTOR USES THIS POSTAL-CARD REPORT FOR CEMENT UNLOADED

System Eliminates Delays

For two years the county has furnished contractors with all cement, sand and gravel f.o.b. cars at the nearest railway station. The contractor hauls the material to the work and includes this expense in the labor cost. This plan has its disadvantages, but its success, on the whole, has been great. During the period in which the plan has been in operation, there has not been a single delay of moment in the supply of material,

and the season's work has been increased 50%. Contractors were at first a little skeptical, perhaps, of the innovation, but today it is doubtful that a single contractor would vote to return to the old plan.

Success in supplying and distributing materials by the county has been the result of the system. Each company from which material is bought sends to the county commissioner daily a notification card for each car shipped. This card is of a form devised and furnished by the county, so that there may be uniformity of reports. When the notification card is received it is placed in the live-card file. The card bears the car initials and numbers, kind of materials, weight, destination of car, etc., and is filed under the name of the road on which the materials are to be used and the name of the station to which the car is shipped. For each car an unloading report card is made out and sent to county headquarters by the foreman at the point of unloading. This card differs in color from the notification card and bears car initials and number, weight, date received, date spotted and date unloaded. The form of these cards is shown in an illustration. When the latter card is received from the foreman, it is checked with the corresponding notification card and inserted behind it in the live-card file. When the freight bill is received it is checked with the cards on file, and then the three are indexed and filed in the permanent file under the job name. This gives for quick reference a history of every car of materials. A special postal-card report form is provided, as shown in another illustration, for the contractor to use in reporting cement unloaded.

Report Cards Alone Not Enough

Report cards, however well devised, are alone not sufficient to control shipments. Regularity in making out and forwarding the cards must be assured. To make certain that the unloading foremen do not fail to make reports promptly and regularly, they are first supplied with stamped and addressed envelopes. Whether they have to report one car or a dozen, they must mail the report the night when cars are received, and, if they do not, a penalty is imposed. Once a foreman thus learns that his instructions mean what they say, little trouble is experienced in getting prompt reports—and promptness is essential if materials are to be routed and distributed accurately.

Each morning, at a certain time, the agent of each station at which shipments arrive is called by telephone, and from him is obtained a list of the loaded cars on track at his station. Having these lists and the card reports previously mentioned, and having also the report of the inspector on each job for the previous day, as to how much material was received and how much was used, the companies supplying materials are called by telephone, and orders are given for destination and routing of the day's shipments. Also, means can be taken if necessary to divert cars in transit to new destinations. If one job happens to be shut down, the material is diverted to that other job where it is most needed. If trucks break down or cars pile up, or for any reason it is apparent that material cannot be handled at one point, it is diverted to another point where it can be handled.

Recapitulated, the force employed comprises the assistant highway commissioner, who purchases and directs distribution; the county road inspectors, who report daily the amounts of materials received and used on the jobs; the unloading foremen, who report daily on the cars received and unloaded, and one office clerk. One-half of the assistant commissioner's salary and expenses is charged to materials management, since half his time is devoted to general supervision and inspection of construction. All of the office clerk's time is charged. The county inspectors report on materials as a part of their regular duties. Since they would be employed and receive the same pay whether or not the county supplied materials, no charge is made for their services. Also, since the unloading foremen are the contractor's regular foremen and the daily report which they make is incidental to their regular work, no charge is made against materials management for their services.

Based on the past season's work, from May 1 to Sept. 1, inclusive, during which period there were used in construction 1410 carloads of sand and gravel and 210 carloads of cement, the charges for materials management were:

Assistant commissioner (one-half time)	$600.00
Office clerk (full time)	320.00
Telephone charges	94.90
Printing, stationery, postage, etc.	102.90
Total	$1117.80

These figures are the true and actual records, and may be verified by the accounts and vouchers on file in the office of the county highway commissioner. They permit the following deductions:

Number of cars handled	1620
Average cost per car, cents	69
Number of cars sand and gravel	1410
Cost per car (1410 x 69c.)	$972.90
Contents of cars, cubic yards	54,990
Cost per cubic yard, cents	1.77
Carloads cement handled	210
Cost per car (210 x 69c.)	$144.90
Barrels of cement	42,100
Cost per barrel, cents	0.344

Briefly, then, by the plan described, the county has eliminated demurrage and kept cars moving. In two years there has been no delay in construction due to lack of materials. The cost has been moderate.

Cement Production Falls Off

Statistics and estimates of the production of portland cement in 1918, compiled under the direction of Ernest F. Burchard, of the United States Geological Survey, Department of the Interior, shows a marked decrease in the total output; in fact, the output was the lowest since 1909. The estimated shipments of portland cement in 1918 amounted to 71,645,000 bbl., valued at $113,910,000, compared with 90,703,474 bbl., valued at $122,775,088, in 1917, a decrease in quantity of 21% and in value of 7.2 per cent. The estimated production in 1918 was 71,632,000 bbl., compared with 92,814,202 bbl., in 1917, a decrease of 22.8%. The stocks at the mills increased from 10,462,822 bbl. in 1917 to about 10,594,000 bbl. in 1918, or 1.3 per cent. The exports of hydraulic cement from the United States for the first 11 months of 1918 amounted to 2,025,178 bbl., valued at $5,257,285, or $2.59 per barrel. The exports for the whole year 1917 were 2,586,215 bbl., valued at $5,328,536, or $2.06 per barrel. The export trade also therefore fell short of that for 1917.

The Economic Duties of the Engineer

By W. R. Ingalls
Editor, "Engineering and Mining Journal," New York

In the presidential address before the Mining and Metallurgical Society of America, Jan. 14, 1919, W. R. Ingalls presented a discussion of the present duties of engineers in relation to the economic problems of the immediate future. The portions of this address which concern civil engineers most directly are here reproduced. After emphasizing the great fundamental economic laws, he analyzes the distribution of wealth in this country and asserts that labor gets what is left after taxes, rent, interest and profits have been paid, and that "what it gets is what it produces." Hence follow the necessity and value of greater production, especially in view of the increased alertness and intelligence being applied to methods of production in Europe. The need for promotion of human welfare by the engineer, and his obligations in this direction, are insisted upon. Of the trinity of production—labor, capital and talent—Mr. Ingalls asks who among the talented are so eminent as the engineer, and closes with an indictment of engineering societies and a strong appeal for an awakening to economic duty.—Editor.

SUPERIOR to all industrial and political principles are economic laws, for it is those laws, which are laws of nature, that create and determine principles and practices. One of the greatest of economic laws is that of the survival of the fittest, which exhibits itself in competition, and from that is derived the classic economic doctrine that labor is the residual claimant upon the produce of industry. After the shares of the state, the landlord, the capitalist, and the *entrepreneur* have been deducted, all the rest goes to labor, and here is what is mystifying to many—to wit, rent, interest, and profits are limited by competition, and of them the laborer can get neither the share of the landlord nor of the *entrepreneur* by any economic means, while, as for interest, the residual claimant is benefited by every payment on account of capital used in the production of wealth, and is better off when a high rate of interest is being paid than when a low rate is paid. We may apply the principles to the concrete case of the United States.

The wealth of the United States at the end of 1916 was estimated at about $250,000,000,000. The production of things was about $50,000,000,000. These are very rough figures, as they are bound to be. Estimates relating to this subject vary considerably. I have mentioned the highest that I have seen. There is reason to suppose that the higher figures are more nearly correct than the lower. Anyhow, I am going to use the highest only to give an approximate idea of proportions. This was before the United States entered the war, and, according to the United States Bureau of Labor, we had 40,000,000 workers. Let us assume that rent, interest, and profits averaged 4% of the wealth of the nation, which would hardly be extravagant. That would account for $10,000,000,000 out of the total product, leaving $40,000,000,000 for labor, or $1000 per worker. Two million railway workers and 250,000 iron and steel workmen received about that sum. Those figures are specific expressions of two whole industries. The workmen in some other industries earned more; in some they earned less.

That labor does not get increased wages at the expense of capital (unless capital be confiscated, in which event the increased wages will not long endure) is illustrated by the experience with the railways in Great Britain and America. The Governments guaranteed the bond and stock holders their average return for a series of pre-war years. In the United States this was $1,000,000,000 per annum, or just about 5% on the capital as reported by the Interstate Commerce Commission. The increase of $800,000,000 in wages has been paid by the public in higher freight and passenger rates. To have left the roads in private hands, compelling them to pay higher wages without permission to make higher charges, would have resulted, first, in impaired service and finally in the state having to take over the lines and supply the deficit in order to have any service at all, just as has happened with some of the street-railway lines in Massachusetts. Thus, what is virtual confiscation aids the wage earner only slightly and only temporarily.

But, apart from confiscation, the winning of increased wages by one group of labor is obtained only at the expense of other groups. The inequality in the distribution of wealth is not between the capitalist and the laborer, but rather is it among laborers themselves. There is ample ground for the surmise that the professional, clerical, shop-tending, and similar classes, and the salaried classes generally, have suffered especially at the hands of the railway operators, mechanics, artisans, builders, and miners, but the farmers and the factory folk have not been immune.

I am not going to enter upon any fine analysis of the very rough statistical data that I have given, and shall point out merely that after the state, the landlord, the capitalist and the *entrepreneur* have got their taxes, rent, interest and profits, of which the last three are severely limited by competition, labor gets all the rest, and what it gets is what it produces. The only way it can get more is to produce more.

It is unfortunate that the only way of expressing production is in terms of money. If it were possible to express it in terms of goods, there would be less misunderstanding. However, it is clear that if the total goods and the total population remained the same, it would not matter if the money value of the goods

fell from \$50,000,000,000 to \$30,000,000,000—i.e., it would not matter at all if money wages fell from \$1000 per annum to \$600, as, indeed, they would fall inevitably. On the other hand, if commodity prices remained the same, and the value of products should rise from \$30,000,000,000 to \$50,000,000,000, labor would get so much more, for it would be producing more goods. This is the only way that the war scale of wages can be maintained, and it is a problem of capital, labor and talent to coöperate in accomplishing it, for only by coöperation can it be done.

Classic Economic Doctrine

This is no preaching of capitalism as commonly understood, but is simply classic and proved economic doctrine. The workman who wastes time and material, the farmer who lets himself be led astray by foolish agrarian policies, the small miner who is similarly misled, the manufacturer and the railway company which fail to adopt efficient methods, the interests large and small which create monopolies or enter into agreements to exact noncompetitive prices—all of these are counteragents to progress in human welfare, although in varying degrees. Probably, on the whole, there is more intelligence among the great corporations than there is among the labor unions, and a better understanding of economic principles, but there are some labor unions whose leadership is bright and some corporations whose management is stupid, while of both there are many that are only mediocre. My thesis is rather that the only way whereby the condition of the mass of the people can be improved is for it to produce more, and the loss of capital and life that has been suffered during the last 4½ years makes it particularly essential now to give attention to increased production, to accomplish which we shall undoubtedly need to develop new systems and new methods. This is what I mean by the necessity for reorganization, rather than readjustment, after the war. And it is in such reorganization that the engineer must play a great part. England is already making her plans, and unless we are careful she will get the start of us. Thus, I recently noted the following paragraph in a letter from an observant American traveling abroad:

"England is knitting together for work. The directors of capital and the organizers of labor were never more together. There have been no strikes in England against capital, only against Government wages or failure of Government to equalize matters as between war bonuses and high cost of living. England is studying efficiency and is preparing for the overseas competition of the future. Forty-six English factories, without trade union or labor opposition, have adopted scientific management, but no stop-watch can be used in any factory controlled by the United States Government, nor is it allowed by the labor unions to make studies in time or motion, or to compile records to promote individual efficiency."

Now, more than ever, should labor in this country be taught that its real interest is to produce more, which is to earn more, and employers should not attempt to diminish labor's residual claim by abolishing competition among themselves or artificially enhancing profits by other means. And just as it is the interest of labor to earn the maximum, so is it the duty of the employer, which means that he should ever be alert to improve his methods of production. Wide differences of plant efficiency, administration, etc., are really the inspiration of social unrest among workers, rather than conditions that are intentionally designed to be evil. The social reformer, who does not understand production, is a far less important person in the promotion of human welfare than the engineer, who does.

America and Great Britain may be in no danger of either political or industrial socialism—the results of the recent elections in each country are reassuring as to that—but, nevertheless, some of the virus has got into us, and, anyhow, our affairs are bound to be affected by the back-wash from the revolutions in Russia and in Germany. Those adversities come on top of the direct destruction by the war in the countries that have preserved their stability. You may mark my words that the engineer is going to have from now on such obligations as he never had before. How he will live up to them remains to be seen. Certainly he will live up to them best if he knows what they be. I can do no more than state them as I see them. Perhaps I see only a few of them. Without any doubt I fail to see all of them.

Study Sound Economic Doctrine

First of all, what I see is that the engineer should saturate himself with sound economic doctrine. This is just as much the basis of his professional work as are the sciences of physics and chemistry; and the fundamental laws of economics are just as immutable as are the laws of gravitation and indestructibility of matter. The engineer-economist cannot possibly be a socialist, or a semi-socialist, nor even an industrial democrat; for it is his business to produce, and socialistic tenets do not tend toward production.

The engineer must be not only a counteragent against the destructiveness of the proletariat, but also must he direct himself against the sluggishness of tortoise-like capitalists. One of the cardinal principles of American engineering during the last 20 years has been the exchange of information and the promotion of publicity about everything—technical processes, business relations, corporate affairs. We have seen America forge ahead largely owing to the absorption of this idea, while Great Britain lagged behind and almost went asleep at the switch. She is wide awake now. Let nobody forget it. But we ourselves have got to go further in publicity than we have gone heretofore. Publicity has been a favorite word among us, especially among mining engineers, who have created more openness in the affairs of their profession and their corporations than exists anywhere else. In reading one of Hobson's treatises not long ago I found a word that struck me more emphatically than publicity. He spoke about transparency, and said that "Perfect transparency of industrial operations, perfect fluidity of labor and of wealth, would effect incalculably great economies in the production of commercial wealth." And he said further: "No fact bearing on prices, wages, profits, methods of production, etc., merely concerns a single firm or a single body of workers." The more you think about that the more will you be impressed by its truth and its merit. Further

effort toward perfecting the transparency of industry is, then, another of the economic duties of the engineer for the promotion of the production of wealth.

Must Harmonize Labor and Capital

I have just quoted from Hobson's work on the "Evolution of Modern Capitalism." In an addendum to that book, written in August, 1916, he outlined post-war economic problems in a way that was prophetic. Let me quote one paragraph: "After the war, the task of economic reconstruction will compel the adoption of bolder experiments, both in public and private enterprise, than had hitherto been thought possible. To realize the enlarged productivity, more pacific coöperation between capital and labor, employer and employed, is a first essential. The immediate peril of an economic situation in which labor seems liable to a sudden fall of wage from the artificially inflated war level will evoke conscious efforts to find ways of harmonizing the interests of capital and labor. The issue is one of devising adequate and reliable stimuli to draw from the workers a larger and more regular output of productive energy, a greater willingness to adopt and apply new mechanical and business methods, and, in general, to coöperate more effectively with the other factors of production."

There was real vision in that forecast of 30 months ago. I may be captious in my criticism of it for its reference to capital and labor, which antithetical representation of two parties alone is always irritating to me. Even some of the socialistic writers recognized many years ago that it was necessary to consider the talented classes as well as the laboring and capitalistic; and recently Lenine and Trotzky, appreciating that the confiscation of capitalistic wealth would not reduce Russia to a dead level of equality so long as they allowed talent to exist, logically began the massacre of the intelligentsia. Labor, capital and talent are a trinity, which one of our rough-and-ready philosophers not long ago represented as a three-legged stool. Among the talented, who are so eminent as the engineers, and whose is more clearly the duty of devising the new stimuli that must be provided?

But while devising stimuli for the workmen let us not forget the need for opening the eyes of the employer to his own defects, and I do not mean defects in his human relations, but rather his economic defects. For an employer may be a generous and lovable captain, whom those working for him may affectionately call "the old man," and yet he may be their worst enemy, an economic impediment, owing to his ignorance and backwardness. Just as there is a class of no-rent lands which determine the price of agricultural produce, so is there a class of no-profit employers who determine the rate of wages.

Sometimes we see the backward manufacturer stirred to new and better things by the threat of imminent extinction through the advent of a new competitive process. Thus, about 20 years ago the contact process of making sulphuric acid promised to displace the classic chamber process, and abolish millions of dollars invested in plant, but the chamber-process men bestirred themselves, improved their practice, and held their own. Right now we see in the electrolytic process of zinc extraction a dire threat against the distillers, and the probable dislodgment of some of them. There will not be an extinction of them as a class, but there will be a case of the survival of the fittest; and those will be the fittest who first improve their practices in ways for which there is room, but which they will not take until necessity drives, necessity in this case being the danger of losing all of their capital tied up in plant.

We have seen how in antebellum days Great Britain practically lost important metallurgical industries, such as zinc smelting and copper smelting, in which she was once preëminent, and we see her now keenly studying and introducing improvements that will rejuvenate her and not unlikely put her ahead of us if we do not look out. Similarly in France, Spain, and other countries, where important steps are already being taken. But few people here appreciate the alertness and intelligence with which the Europeans are entering upon a new program, for the simple reason that they know they have got to do it. It is one of the immediate economic duties of American engineers to see that our own industries do not become blind to the reorganization that is being started elsewhere and ought also to be considered here. I am not now thinking in terms of individual enterprises, many of which may be, and doubtless are, very efficient; but rather am I thinking of industries as a whole.

And just as we must think of industries as a whole, so also must engineers think and act as a whole. The individual, no matter how superior he may be, cannot alone make very much of an impression. Indeed, his influence may be greater abroad than at home, and may be more to the advantage of foreign people than his own if he be unsupported by a body of colleagues at home, as witness the influence of Orville and Wilbur Wright in aëronautics.

Indictment of Engineering Societies

I think it is an indictment of the engineering societies of this country that they have made no general efforts for the advancement of economic conditions. Their meetings have been pleasant social functions, the benefit of which is not to be decried. Their printed transactions have been the repositories of valuable technical papers, which are useful for reference and guidance. But in their practical indications, in their practical push toward better things, they have been insignificant in comparison with the splendid efforts of the American engineering press, respecting which we may proudly say, *"Ne plus ultra."* Pray forgive any impropriety in my expressing this, for of course I have not in mind my own trifling part in what hundreds of papers have done with the coöperation of the industries and professions that they represent.

The Mining and Metallurgical Society of America is one of the few professional organizations that have aimed to improve economic conditions by active concerted pressure representing the consensus of professional opinion. Its efforts have naturally been confined to its own industry. In spite of its small membership, which smallness is, after all, inconsequential, so long as there is the right quality of membership, this society undeniably did most in recent years to improve the transparency of the mining industry. With equal assurance may it claim the credit of giving the impetus to the movement for greater

safety for miners. And also may it claim the crystallizing of the movement for a reform of our archaic mining laws upon new lines, as to which the mining industry is in almost unanimous agreement, the actual drafting of the new legislation having been delayed by the advent of the war. It is exactly such kind of work, now with regard to some broad economic principle, now with regard to some plans for new legislation, and at other times, at the present time, with regard to purely technical questions such as the status and particular problems of the copper, lead, zinc, or iron mining industries, that mining and metallurgical engineers must act unitedly through a body like this, if we are going to achieve the right reorganization in this country. And what we do in our particular field, so must the civil, mechanical, and electrical engineers do in theirs.

Engineers' Services in the War

With the entry of the United States into the war, the engineers of the country, like everybody else, enthusiastically offered their services to the Government. I think that the engineers were particularly eager, for they knew from the previous experience of our allies that it was an engineering war. Our own members, and those of other societies, and engineers generally, entered the services and undertook duties at Washington and elsewhere in great numbers. Now, far be it from my thought to minimize their accomplishments. The job was done, the war was won, sooner than we expected and more victoriously than anybody ventured to prophesy; and that was the principal thing. We performed some marvelous engineering feats in building cantonments, in repairing the German ships, in organizing and equipping a great army and transporting it to France, in building shipyards and ships, in feeding our allies and supplying them with materials. I cannot hope to enumerate all the praiseworthy things that we did, largely through the instrumentality of our engineers. Yet I cannot overlook that according to General Pershing's official report, made after the armistice, his armies had fought with French guns, British tanks, and French and British airplanes, although 19 months had elapsed since the United States entered the war. Nor can I forget the coal famine, and other industrial troubles in this country, and consider that the engineers of the country did all that they might. It was not their fault that they did not. They wanted to do everything in the best way, anyhow to give the best that was in themselves. The engineering societies did loyal and effective work in so far as they were asked or permitted. Yet is seems to me that the delay in starting shipbuilding, the subsequent airplane fiasco, the mess about making the 75-millimeter guns, and some mix-ups in our own industry, show that our engineering bodies did not exercise the pressure toward prompt and successful accomplishment that they might have done. Sometimes, when we knew that things were going wrong, we let ourselves be swayed by emotions and by condonations that anyone of us would have regarded as short of his duty to an individual client.

The wicked war is now ended, thank God, and the hurly-burly of doing thinks quickly, without counting cost, is past. We are entering upon an era not merely of reconstruction or readjustment, but of reorganization, in which it will be many years before we shall be able to form much of an idea of what the result is going to be. There is every probability that engineers are going to be called upon to play a great part in this, and now, fortunately, they will be able to give more deliberate consideration to the study of problems and the formulation of plans than they could during the war. They will have to work individually and also concertedly through professional bodies like this. If they fail to do so, they will be derelict not only in their economic duty, but also in their duty as citizens of the Great Republic, whose welfare must not be permitted to suffer during the coming period of competition and elevation among our friends and rivals.

Society Service

A Section Dealing with the Results of Teamwork by Technical Men

Association Seeks Better Pay for Railway Engineers

In its campaign for fair play for railway technical engineers, the American Association of Engineers has issued a circular giving schedules of monthly pay recommended by three leading chief engineers as follows:

	A	B	C
Division engineer	$300 to $400	$325 to $350	$320
Assistant engineer	250 to 300	224 to 240	225
Instrumentman	175 to 200	$175	190
Rodman	75 to 90	145	125
Tapeman	60 to 75	120	90
Draftsman	130 to 175	150 to 200	175
Chief draftsman	200 to 250	250	250

This circular also announces a plan for financing the campaign, by setting aside half the receipts from new railway members during January, and by soliciting subscriptions from present members and engineers who are not members. This fund will be used to make a study of the wages paid to technical engineers in railway service, and to present the results to the Board of Wages and Working Conditions of the United States Railroad Administration.

Participator Gets Greatest Benefit From Serving Societies

That the benefit of society work and the return is of most value to the member who participates, is one of the points too many young engineers are inclined to forget. The return is prompt and positive, said Charles B. Burdick, president of the Western Society of Engineers, at the recent annual meeting. His further views along the same line follow:

"He educates himself in presenting his message to others. It is no doubt true generally that none receives a greater benefit from an engineering paper than the man who prepares it. Those who miss the opportunity thus to benefit from the society lose one of its chief advantages.

"But we are not all benefited to an equal degree, nor is the gain equal from year to year. Some will reach

a time when perhaps their duties are of such executive nature that they get out of touch with pure engineering, and some may feel that society work is too great a burden, and the *unthinking* may reach the point where he questions its value because he personally does not feel the need of it. If so, then it is well to remember that the society represents all grades of membership, that there are others less fortunate who need to keep abreast of the engineering times, and who need the acquaintance that comes from contact in the work of the society. From the standpoint of earning capacity, the engineer has no better asset than to be well and favorably known among engineers. This is true regardless of the engineer's position, whether he is engaged in purely scientific or commercial endeavor, whether depending on fees for a livelihood or working for a small salary."

Mr. Burdick's positive statements with reference to compensation will cheer the young man. He said, "I believe the society is justified in proper efforts looking toward better compensation for engineers, but anything savoring of trade unionism would be the most positive detriment. The engineer's best stock in trade is his absolute loyalty to the job. It opens fields of unlimited possibilities that would be closed, and properly so, by any evidence of a tendency to coerce, or to standardize service.

"But there are many things we *can* do that would be in the interest of the individual engineer and the public; no doubt more than we have done in the past. We can use our influence to see that technical men are appointed to public positions requiring technical skill, and that remuneration is provided sufficient to attract men of capability. We can help to educate the public to better appreciation of engineering and the necessity for adequate compensation. We can increase our facilities for solving the question of unemployment, particularly among our members."

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Ratio of Tensile to Compressive Unit Stress Should Be Increased

Sir—I have noted with interest Dr. Waddell's suggestion, in your issue of Jan. 16, p. 155, that riveted truss bridges of 100-ft. span be tested by the Bureau of Standards at Washington. Such tests should be an advance over the present methods of testing columns and tension members, and would add to our knowledge. A very great advance was made in our knowledge when full-size tests replaced specimen tests.

The writer believes, however, that the tendency in the American Railway Engineering Association to alter the relation that has existed between compression and tension working stresses is rational and in the right direction. Column tests made some years ago showed that the same proportion existed between the elastic limits and ultimates of full-sized columns, and of full-sized tension members.

Engineers can hardly be said to be hasty in altering the working stresses. The writer believes that safe working stresses in bridge columns could be represented by the formula $14{,}000 - 0.272\,(l/r)^2$, corresponding to safe working stresses in tension of 20,000 pounds per square inch.

There is no denying that if this new tendency is correct much metal has been wasted in tension members of bridges. A similar reasoning leads one to believe that much metal has been wasted in tension flanges of girders—for, as Dr. Waddell points out, consistency requires lower unit stresses in compression flanges than are now used, or higher unit stresses in tension flanges. It would seem that the latter course is safe. The writer further believes that present specifications require altogether too many web stiffeners.

A series of tests of riveted truss bridges would certainly settle the question of relative compression and tension stresses. It would add much to our knowledge of the behavior of members in actual structures.

Rapid-Transit Construction Should Be Separated From Regulation

Sir—I have seen little or no comment, in either *Engineering News-Record* or any other paper or magazine, relative to the very drastic and pertinent recommendations made by Governor Smith in his message to the legislature of New York, on Jan. 1, 1919, concerning the reorganization of the Public Service Commissions of the state. It does not appear that this matter is receiving the attention that its importance to the city and state demands.

The Governor proposes to take away from the Public Service Commission of the First District all control and supervision over rapid-transit construction work in New York City, and to place it under the control and direction of a rapid transit commissioner, who would devote his entire time to the completion of the construction work. In this recommendation the Governor goes to the very heart of the trouble that has afflicted rapid-transit work from its very inception. If, in the beginning of the work on the dual systems, a single commissioner with full powers had been put in charge, it is more than probable that—even including delays incident to the war—all work under the dual system contracts would have been completed months ago.

With a commission composed of five members, all with equal powers, responsible collectively but not individually, it could easily have been foreseen that delays in carrying out the work would follow inevitably. With such a commission, whose personnel was continually changing in whole or in part almost yearly—new commissioners coming in with new ideas—it was difficult if not impossible to formulate any policy that was likely to stand for any length of time. This has led to end-

less delays and much confusion in the rapid execution of the work.

In addition to its supervision of rapid-transit construction work the Public Service Commission has its primary function to perform, the regulation of public utilities. Therefore, its full time and energy could not be devoted to the construction work. The commission has been handicapped from the very beginning by the method provided by law for handling the work; the method and not the commission is mainly at fault. A great deal of the criticism that has been raised against the commission, on account of the delays in completing rapid-transit construction work, is in many instances both unfair and unjust; it seems to be conceded that the commissioners generally have endeavored to carry out the work both honestly and faithfully; the failure of the commission to function properly must to a very large extent be set down to the mistake that was made in providing a method of supervision that was both cumbersome and inefficient. This appears to be the opinion of most of those who have given the matter much thought.

One of the great object lessons of the war has been that, if results are to be obtained along any line of endeavor, responsibility must be fixed by giving to a single qualified executive full powers and purisdiction. This was demonstrated also in the construction of the Panama Canal; if General Goethals had not had full authority in connection with all construction, it is more than probable that the canal would not be finished yet. The proposal of the Governor to place rapid-transit construction work in the hands of a single commissioner, with full power and responsibility, is sound and is dictated by the hard-learned lessons of past experience.

To engineers especially, and to all those who are interested in the early completion of the rapid transit systems in this city, this is a matter of vital importance, and it would seem that every effort should be made by engineers and the public generally to aid the Governor in obtaining the necessary legislation.

If the statements in the public press are to be believed, it is the intention of the Governor to appoint an engineer as rapid-transit construction commissioner, if the necessary legislation is enacted. This is also to be commended as sound policy and very essential if the work is to be brought to rapid completion.

The Governor has further recommended other radical changes in the organization of the Public Service Commissions of the First and Second Districts. He proposes to do away with the present five-headed commissions and to substitute therefore, in each district, a single commissioner with four deputies; this appears also to be a step in the right direction, as it will not only fix responsibility on a single individual, but will tend toward increased efficiency.

If the commissions are organized along the lines proposed, and the public service commission act is amended so that power is given to the commissioner to enforce his orders without undue delay, much of the discontent and dissatisfaction now existing will be very materially modified.

The legislation proposed by the Governor appears to be so necessary and essential to the welfare of the public generally that I believe the greatest publicity should be given the matter. I have therefore taken this opportunity of writing you at length. ALFRED LUDWIG.

103 West 54th St., New York.

More Comment on Engineers' Salaries

Sir—The letter of Professor Barnes in your issue of Dec. 26, under the caption, "Why Offer Such Low Government Salaries?" reminds me of a recent request addressed to the writer by the wife of a mechanic here in Toledo. She said:

"Please secure a job for my husband at the Air Nitrate plant which will pay as much as the night engineers are receiving there; viz., \$9.15 per night, or nearly \$300.00 per month, as they are on duty every night."

It looks as though Uncle Sam were penalizing the man who possessed both theoretical and practical knowledge, and favoring him whose training is strictly practical. I wonder why this is so? W. J. SHERMAN,

Toledo, Ohio. Consulting Engineer.

Sir—I have read with interest the criticisms which have recently appeared in your columns of the low remuneration earned by civil engineers in America, and as a member of the profession, not an American, but merely a visitor, it would seem to me these criticisms are entirely justified.

I recall an interesting incident which occurred on my first arrival in this country to complete my technical education—a conversation I had with a man who was painting my room. He inquired what course I was studying, and on my replying, "Civil engineering," it was evident that he regarded me as either an ass or an imbecile. Then he asked me if I intended to settle in America. I replied in the negative, on which he remarked it was a good thing, as, if I did, I should starve. He cited the harrowing experience of one of his nephews who had striven hard for a technical education, had been graduated as a civil engineer, and, after working for the munificent salary of \$10 a week for a couple of years—this was before the war—had thrown the calling over in disgust and turned to something else.

There is something radically wrong somewhere with the organization of engineers, and members of the profession must wake up and help themselves, since it is waiting for the millennium to expect others to help them. Is it not a disgrace that those who are supposed to possess organizing ability in a peculiar degree should evince so little of this talent in the protection of their own interests? If civil engineering societies serve no purpose other than to provide opportunities for their members to read voluminous papers on professional subjects, then it is time for engineers in America to decide whether they do not fall short of their proper function.

Engineers must be brought to realize that in furthering their pecuniary interests they are doing something neither unprofessional nor derogatory to their self-respect as individuals. Staunch coöperation secured for the medical fraternity their present recognized status, and only similar effort on the part of engineers can

better a state of affairs which all of the calling, I think, are agreed is nothing short of disgraceful. As a first step in this direction, it would be a good thing if engineers agreed to admit to membership only those able to furnish satisfactory evidence of professional competency, examinations to be instituted to determine the latter qualification. The second step would be for engineers to decide precisely what constitutes civil engineering, to press for the enactment of legislation making compulsory the employment of civil engineers in the supervision of all activities falling within this definition, and to refuse to work with or employ anyone not properly qualified as a civil engineer. A. E. GOLDING.

New Haven, Conn.

RATES OF PAY FOR DRAFTSMEN AND COPYISTS, AWARDED BY DECISION OF THE SHIPBUILDING LABOR ADJUSTMENT BOARD

Oct. 1, 1918

Class	Rates Per Hour	Day	Week	Month	Year
Second-class copyist......	$0.40	$3.20	$17.60	$76.27	$915.20
First-class copyist........	.50	4.00	22.00	95.33	1,144.00
	.60	4.20	26.40	114.40	1,372.80
Draftsman, Grade C......	.65	5.20	28.60	123.93	1,487.20
Draftsman, Grade B......	.75	6.00	33.00	143.00	1,716.00

EXPERIENCE REQUIRED

Class	Previous Experience	Education
Second-class copyists,	None	No special.
First-class copyists,	6 months	or 6 months' technical.
Draftsman, Grade C,	2 to 3 years	or technical school graduate.
Draftsman, Grade B,	4 years	or technical gradute with some experience.
Draftsman, Grade A,	5 years	or technical graduate with 1 year's experience.
Charge man,	5 years	or technical gradute with 2 years' experience.
	7½ years	or technical graduate with 4½ years' experience

Sir—In *Engineering News-Record* of Dec. 26, p. 1192, I noticed a letter from Prof. A. F. Barnes, dean of engineering, New Mexico College, discussing the low rates of pay offered to draftsmen by the Navy Department. He also quotes from a civil service announcement that "the department is finding some difficulty in obtaining, for the rates of pay it has to offer, men with the qualifications necessary to meet its requirements." He also discusses further the low rates of pay offered to engineers in general by the Government departments.

The answer to the Navy Department statement may be found in the decision by the Shipbuilding Labor Adjustment Board of Oct. 1, 1918, in Section XVII of which rates of pay for draftsmen are authorized. The decision is quoted below:

"In response to the request of the Navy Department and the Emergency Fleet Corporation, of representatives of the employees affected, and of many of the shipbuilding companies, we have held hearings and made a careful study of the compensation and privileges enjoyed by draftsmen, with a view to standardizing these conditions in the shipyards under our jurisdiction. On the basis of this study we direct that in all shipyards building vessels under direct contract with the Navy Department, or the Emergency Fleet Corporation, the compensation, hours and conditions of employment of draftsmen and copyists conform to the following regulations, to be made effective in such shipyards with the pay periods beginning on Oct. 1, 1918, or immediately thereafter.

"First: Draftsmen and copyists are to be subdivided into the following defined classes, and are to receive the compensation indicated:

"*Charge Man*—Man who is in responsible charge of the drafting work on one or more ships and who is supervising its execution. Must have had five years' experience in marine drafting, or be a graduate of a technical school in the course in engineering or architecture, and in addition have had two years' experience in a shipyard. Rate per hour $1.25 during the first six months' service in this class and to increase 5c. per hour at the end of each six months' period to a maximum of $1.50 per hour.

"*Draftsman, Grade A*—Man laying out and developing work completely from specification. Must have had two years' experience as draftsman in Grade B, or five years' drafting or equivalent experience outside of a shipyard, or be a graduate of a technical school in the course in engineering or architecture, and, in addition, have had one year's experience in a shipyard. Rate per hour $1 during the first six months' service in this grade, and to increase 5c. per hour at the end of each six months' period to a maximum of $1.20 per hour.

"*Draftsman, Grade B*—Man designing details. Must have served one year as draftsman in Grade C, or be a graduate of a technical school in the course of engineering or architecture, with some shipyard experience, or have had four years' drafting or equivalent experience outside of a shipyard. Rate per hour $0.75 during the first six months' service in this grade, and to increase 5c. per hour at the end of each six months' period to a maximum of $0.90 per hour.

"*Draftsman, Grade C*—Man handling details under supervision. Must have had two years' experience in a shipyard, or three years' drafting or equivalent experience outside of a shipyard, or be a graduate of a technical school in the course in engineering or architecture. Rate $0.65 per hour.

"*First-Class Copyist*—Man who alters tracing to agree with work or sketches of work, or man starting to do detail work. Must have had six months' experience in a shipyard, or in a drafting room, or in a technical school. Rate per hour $0.50 during the first six months' service in this grade, and to increase 5c. per hour at the end of each six months' period to a maximum of $0.60.

"*Second-Class Copyist*—Man who traces from original work. Rate $0.40 per hour."

In the first paragraph of this section, you will note that "all shipyards building vessels under direct contract with the Navy Department" are directed to follow this decision.

Also, Section XXVI gives the application of this decision and is quoted below:

"This decision shall apply on the Atlantic Coast, Gulf and Great Lakes to shipbuilding and ship-repairing plants, and plants engaged in installing equipment in ships under direct contracts with the Navy Department or the Emergency Fleet Corporation, or the United States Shipping Board, to work performed by subcontractors in such plants or upon such ships being built or repaired under such contracts and to shipyard construction or extension in this district, the expense of which is borne entirely by the Navy Department or the Emergency Fleet Corporation; provided, that rates and

working conditions in connection with such yard construction or extension for building occupations are to be the prevailing rates and working conditions in the building trades in the locality in which the shipyard is situated."

The above quotations are from the decision in Atlantic Coast, Gulf, and Great Lakes shipyards. Section XVII is identical in the decision for Pacific Coast yards.

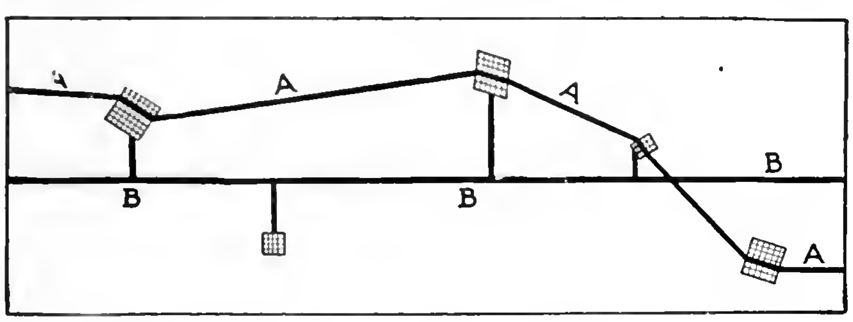
Herewith I have tabulated the rates of pay for different periods, and minimum experience required to qualify for these rates of pay.

I believe that this information should have the widest circulation among engineers, and that this can be secured through publication in *Engineering News-Record*.

Philadelphia, Penn. LLOYD W. WEED,
Concrete Ship Section, Emergency Fleet Corporation.

New Locations for Through Truck Routes

Sir—In the present literature of motor highways more attention is given to construction than to location. It seems to me that, for great highways not chiefly intended for traffic between any two cities, marked advantage would result by such location as would avoid passage of through traffic over the congested streets of the intermediate cities. Such roads would be located



THROUGH ROUTES SHOULD FOLLOW LINE B

not through cities on the route, but near them, to the advantage both of the through traffic and of the intermediate cities and towns. Such location would shorten the distance, and, by giving wider choice of location, could secure more favorable grades and curves.

The sketch illustrates the above thought. Of the two locations, A and B, for a trans-state or transcontinental highway, line B would seem to serve the purpose of freight transportation and through traffic better than line A. At the same time, the streets of the intermediate cities would not be congested with the through traffic. FRANKLIN BACHE.

Philadelphia, Penn.

Labor and Bolshevism

Sir—Your editorials on humanitarian subjects prompt me to submit the following reflections:

So much has been written regarding social conditions throughout the world today that it has seemed strange to the writer that no reference has been made to the wonderfully prophetic poem, "The Man With The Hoe." About 18 years ago Edwin Markham wrote this poem, after seeing Millet's painting of the same name. When the poem was published in the San Francisco *Examiner* of Jan. 8, 1901, there was considerable criticism of it, on the ground that it was an affront to manual labor. That this view was wrong one may easily see by even a casual reading of the poem. The great poet saw that the day would come when the relations of mankind in certain portions of the world would undergo a change. In proof of this I submit the last stanza:

> "O masters, lords and rulers in all lands,
> How will the Future reckon with this man?
> How answer his brute question in that hour
> When whirlwinds and rebellion shake the world?
> How will it be with kingdoms and with kings—
> With those who shaped him to the Thing he is—
> When this dumb Terror shall reply to God,
> After the silence of the centuries?"

We all are too prone to get our cause and effect oriented to suit our own particular viewpoint. The oft repeated words of caution regarding the necessity of guarding against Bolshevik tendencies in our country are due to lack of discrimination between cause and effect. The conception of the painting which inspired this poem was foreign. The poem does not refer to American conditions, political hodge-podgers and Socialistic teachers notwithstanding.

Albany, N. Y. E. W. WENDELL.

Waterproofing Bridge Floors With Burlap

Sir—The writer has read with much interest the very interesting article written by H. T. Welty, engineer of structures of the New York Central R.R., on the waterproofing of railway-bridge floors. In regard to the materials to be used, special emphasis has been laid, in this article, on two points which in the writer's opinion might be subject to some qualifications, and as in the present instance the qualifications are based on practical experience, they may not be uninteresting.

It is stated that the fabric used in the membrane should be thoroughly saturated, and that a cotton drilling so saturated would probably prove to be the best material to be used. It is also stated care should be taken not to overheat the compound used with the fabric.

In 1911-12 the waterproofing of about 50 bridge structures involved in the construction of the New York, Westchester & Boston R.R. was under the care of the writer. On a number of the structures the two conditions above mentioned were purposely violated, and the results have not shown that any defects were produced by this violation. In these constructions a membrane was used composed of a single ply of open-mesh untreated burlap and two coats of a special compound. It was conceded at the time that in many instances burlap which had been used with the ordinary tar and asphalt compounds had, when taken out after several years' use, appeared to be almost burned up. Chemical investigation of this phenomenon had, however, demonstrated, as far as could be judged, that this disintegration was due to the sulphur content in the coal-tar pitch, and many of the grades of asphalt used. The material used in the present instance did not contain sulphur, and such confidence was felt in the above analysis of the cause of disintegration that burlap was used without fear.

As to saturation: One of the chief needs for saturation appears to be the securing of a thorough bond between the fabric and the compound. In the present case, the compound used had such an adhesive quality that the chief difficulty in using it was to prevent it from adhering not only to the burlap but to anything

else with which it might come in contact. There would, therefore, be no difficulty as regards the bonding. Saturation of the fabric before application was thought not to be necessary with the compound used, because, if a thorough bond were obtained and the compound were thoroughly waterproof and really elastic, no water could get into the fabric, and its primary function was merely to hold the compound in place while the cover was being placed. It was also believed that with the compound used partial saturation would actually occur in the field, due to the fact that it was possible to heat this compound material to a very high temperature and apply in a very liquid form—and this leads to the second admonition in Mr. Welty's article, in regard to the question of overheating.

It was quite frankly acknowledged at the time, with the asphalt and tar compounds available, that overheating would destroy them, and this was believed to be due to the driving off by heat of the volatile solvent used in them to obtain plasticity. With the material used, however, the plasticity was not obtained by the use of a volatile solvent, and the material was heated in some instances until it was burning, and was as liquid almost as water.

Now as to results: As far as seven years' service can show, the floors have proved to be remarkably water-tight. A section of the membrane was taken out after four years' service, and has been on file in the office for two more years. The burlap has shown absolutely no evidence of any disintegration of any sort, and is in as perfect condition as on the day it was installed. The compound is bonded to it absolutely, and the burlap, if not quite saturated, has sufficient coating to prevent any possible entrance of water into it. It might be added that the compound itself has remained adhesive and elastic. A. H. RHETT.

320 Fifth Ave., New York City.

Minute Concrete Mix Subject To Some Doubt

Sir—In *Engineering News-Record* of Nov. 28, 1918, p. 966, there was an editorial under the heading "Minute Mix Justified By Extensive Tests," in regard to which the writer, who is familiar with the report that was the basis of this editorial, desires to comment.

Professor Abrams, in the introduction to this report, rightly states that this report must be considered merely preliminary to any comprehensive investigation covering the performance of concrete mixers, but in his conclusions he makes some strikingly general deductions which are emphasized in your editorial.

From tests of a similar nature made at the Bureau of Standards and from extensive observations of field concreting operations, the writer is of the opinion that the conclusions, especially in regard to 1 min. being the most efficient period of mixing, are too general and broad in application. This the writer believes for the following reasons:

First, the results reported in Professor Abrams' paper deal only with concretes in which sand and gravel are the aggregates, and the question of the possible effect on this problem of using aggregates of different character (i. e., crushed stone) is not taken up.

The accompanying table, which includes results of

TESTS ON TIME OF MIXING CONCRETE

Mixer: Chain Belt No. 145

Each result average of 3-8x16 cylinder. Stored in damp closet.

Composition of Concrete (Parts by Volume)	Water, %	Time in Mixer	Compressive Strength Lb. per Square Inch, —Age in Weeks— 2	4	8	13	Average of All Tests
1 part Portland cement, 2 parts Cow Bay sand, 4 parts crushed trap rock ($\frac{1}{4}$ to 1 in.)	8.06	45 sec.	1300	1865	1965	2992	2030
		2 min.	1850	2335	2710	3697	2648
1 part Portland cement, 2 parts Cow Bay sand, 4 parts Cow Bay gravel ($\frac{1}{4}$ to 1 in.)	6.90	45 sec.	1285	1755	1795	3060	1974
		2 min.	1300	1675	1920	2832	1932
1 part Portland cement, 3.15 parts Cow Bay sand, 5.42 parts crushed limestone ($\frac{1}{4}$ to 1 in.)	12.2	45 sec.	....	840	1060	1900	1267
		2 min.	....	1285	1785	2542	1871

The consistency used may be described as a "quaking" consistency, and probably closely resembles what Professor Abrams considers the normal consistency.

some tests made at the Bureau of Standards, indicates that Professor Abrams' deduction as to the proper period for mixing is applicable to sand and gravel concrete, but not to concrete in which either crushed trap rock or crushed limestone is the coarse aggregate.

Second, in this report of Professor Abrams, the facts are evident that the increase in strength due to longer mixing becomes greater as the size of the largest particles decreases. From the writer's observations, made on mixing in the field a rich concrete in which the particle of maximum size was ½ in., it is believed that the increase in strength due, say, to mixing 2 min. rather than 1 min., would be even greater in a 1:2 concrete than in the 1:5 concrete series given in this report, in which the size of the largest particle is varied.

Third, it has been observed that where an effort has been made to approximate 1-min. mixing in the field with a 1:2 mixture, with the largest particle ½ in., there is a distinct tendency for dry balls to appear in the output of the mixer. These are sometimes 3 or 4 in. in diameter, and indicate plainly that the concrete has been imperfectly mixed. In this connection it might be stated that these dry lumps might be easily broken up in molding the test pieces, and no reduction in strength result from their presence, while a quantity of such dry unmixed concrete might be a serious source of trouble in the actual work.

Finally, it is the writer's opinion that it is impossible so to coördinate the operations of filling, mixing and discharging a concrete mixer as to give the materials one full minute in the mixer and approach very near the batch-a-minute output. Where the batch-a-minute performance is accomplished, it is obtained only by greatly decreasing the actual time of mixing. From observations on the operation of some 15 different types of mixers at present on the market, it was noted that practically all of the mixers tried out required at least 30 sec. to dump a reasonable amount of their batch (in this case a 1:2 mortar).

Therefore, the writer believes that, in specifying the proper time of mixing, the mix to be used, the character of aggregate, and at least the type of mixer likely to be employed, should be considered, and a minimum time specified for all the material to be mixed in the drum, and a limit fixed on the number of batches permitted for a given period of time.

Philadelphia, Penn. HERBERT A. DAVIS,
Concrete Ship Section, Emergency Fleet Corporation.

HINTS FOR THE CONTRACTOR

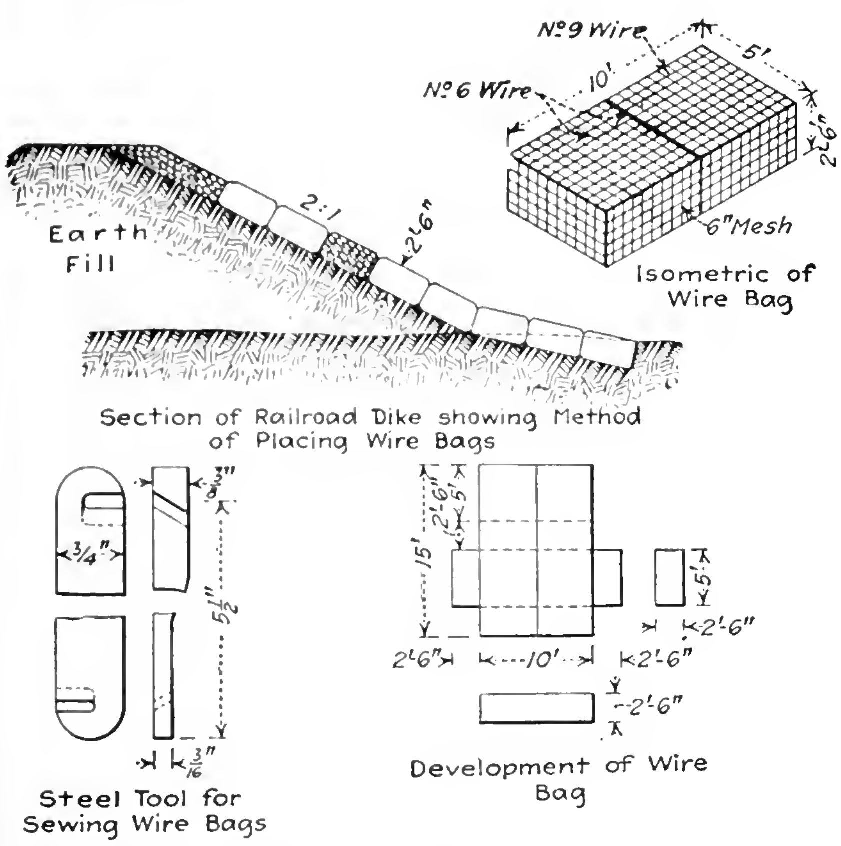
DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Weaving Wire Bags To Hold Riprap on Earth Embankment

EARTH embankments at Lake McMillan, on the Carlsbad project of the United States Reclamation Service are protected by wire bags full of riprap, where the velocity of the current is higher than 5 cubic feet per second.

L. E. Foster, project manager, describes the making of the wire bags, in a recent issue of the *Reclamation Record.*

The bag material, of No. 9 galvanized wire mesh, was cut and sewed in the shop into the developed form shown in the drawing, then folded together flat, and hauled to the work. The bags were then sewed into rectangular



WIRE-MESH BAGS HOLD RIPRAP TO PREVENT SCOUR ON EARTH EMBANKMENT

form with the lid loose. The bags were set in a horizontal row in place and they were filled directly from the rock wagons.

The labor of filling the bags proved to be less than to lay riprap of the same thickness. Care was taken to have all rock next to the wire mesh of greater dimensions than 6 x 6 in. Since this is a relatively small-sized rock, much rock is available for bag work that would be otherwise considered too small for use in riprap.

After the bags were level full the top was closed down and sewed securely on the front and two sides. The bags were also tied to each other along these edges, thus forming a continuous mat.

The tool shown in the drawing was used in sewing together the bags. The ties were placed at 6-in. intervals. Each 5 x 5 x 2½-ft. bag weighed 70 lb. empty and carried 4.63 cu.yd. of riprap.

Other Articles in This Issue of Interest to Contractors:

How the New York Canal Concrete Barge is Being Built — Page 268

Road Building Materials Supply Solved by System — Page 289

On the basis of 259 bags the detail costs of the work are as follows:

Material required per bag:
- 31 lin.ft. of 60-in. wire mesh;
- 11 lin.ft. of 30-in. wire mesh;
- 5 lb. No. 12 tie wire.

Cost:

Cost per square foot, including tie wire	$0.0229
Weight per square foot, including tie wire, pound	0.38
Weight per bag (182.5 sq.ft.), including tie wire, pounds	75.4
Cost per bag (material only)	$4.20

Detail costs:

Material for bags	$4.20
Manufacture of bags ready for placing	.905
Placing and filling bags	1.125
Closing bags and sewing	.446
Total unit cost per bag	6.676
Cost of rock hauling for bag work per cubic yard	0.17
Cost of wire bag work per cubic yard	1.681

Swing Pipe Saves Hose Changes on Concrete Highway Work

By H. H. Edwards

Highway Laboratory, University of Illinois, Urbana, Ill.

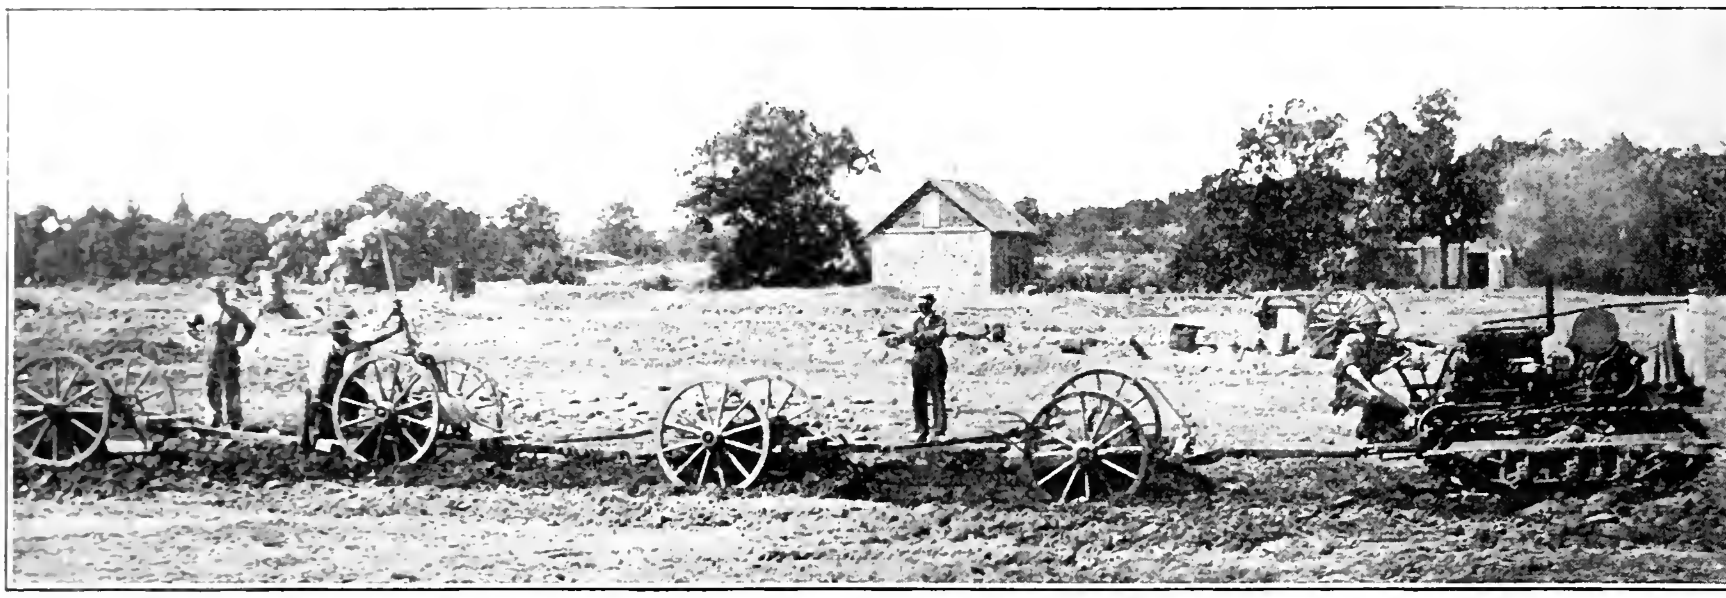
CONSIDERABLE saving of time and labor in the operation of a mixer on highway concrete construction is effected by fitting a swing joint and one or two lengths of pipe to the tee in the water line. Such an arrangement will reduce by one-third the number of times the hose has to be changed, without using an unusual length of expensive hose, which means an added saving.

As seen by the illustration, a nipple and elbow are screwed into the tee, a couple of lengths of pipe are coupled, and the mixer hose is attached to the end. If the length of hose were such that the tees on the main line could be placed 160 ft. apart, by using the 20 ft. of iron pipe as above it would be possible to place the tees 200 ft. apart, thus reducing the number of changes. The length of pipe is first turned toward the mixer from the tee, and, as the mixer moves down the road past the tee, the pipe is flopped over and laid in the other direction.

SWING PIPE REDUCES NUMBER OF HOSE CHANGES

One Tractor Operates Six Wheeled Scrapers

SIX wheeled scrapers coupled together in train were loaded and hauled by a gasoline tractor last summer in mining molding sand near Burlington, Wis. The haul from the pit was $\frac{1}{8}$ mile to a bridge over the loading track where the scrapers dumped through a trap into cars. An evener was fitted across the back of each scraper, and the tongue of each was cut off about one-third. When coupled tongue to evener a space of 8 ft. was left between the scrapers. In operation, four to six scrapers were coupled in tandem, with the forward scraper coupled to a tractor geared to three speeds.



TRACTOR OPERATES TRAIN OF WHEELED SCRAPERS IN GRAVEL PIT

The train was hauled through the pit at low speed, and two men loaded the scrapers one after another. Travel to the dumping bridge was at middle speed, and return, unloaded, was at high speed. At the bridge, dumping devices automatically tripped and righted the scraper bodies. Travel to the dump was at a speed one-third faster than team haulage, and return to the pit was at twice the speed of teams. With a haul of $\frac{1}{8}$ mile and a force of four men, four to five coal cars of ordinary size, about 35 cu.yd. each, were loaded in ten hours. Previously, the same outfit of scrapers required from 15 to 18 men and three teams to accomplish the same task. The tractor scraper outfit was originated by the Walsh Sand & Gravel Co., Burlington, Wis. James Walsh devised the method of coupling the scrapers and also the automatic dumping devices.

Special Traveler Erects Frame of Large Railway Shop

ERECTION of a steel-frame machine shop at Logansport, Ind., for the Pennsylvania Lines West of Pittsburgh, was effected by the use of the double-boom steel traveler shown in the accompanying view. The building is about 475 x 195 ft., with a 250-ton, 90-ft. overhead electric crane in the erecting bay.

The traveler has a deck about 32 x 26 ft., carrying triangular side frames which are braced together and on which are mounted two 60-ft. booms. For each boom the rated hoisting capacity is 10 tons, but 15-ton loads have been handled. Each boom is served by a 30-hp. hoisting engine and boiler, these being mounted on the working deck, 3 ft. above the rails. The track consists of a pair of 80-lb. rails spaced 25 ft. on centers, each rail being laid on ordinary railroad track ties. There are three double-flanged wheels on each side, one at the rear and two at the front, to carry the load from the mast and boom. These are of 12-in. diameter on the tread and are $4\frac{3}{4}$ in. wide over the flanges.

This work is under the direction of Robert Trimble, chief engineer of construction, Pennsylvania Lines West of Pittsburgh. The Austin Co., Cleveland, Ohio, is the contractor, with J. E. Anderson as superintendent.

STEEL TRAVELER READY TO ERECT STRUCTURAL FRAME

Dry Dock Filled by Pumping

A graving dock of moderate size is to be built by a Swedish shipbuilding company at Ljusne, North Sweden, on land above water level, and will be filled by pumping. London *Engineering* says the dock will be 328 ft. long and of such size as to accommodate a 4000-ton vessel. The boat to be docked will enter a lock and will be raised and lifted into the dock by means of water from an adjacent water-power canal. By this arrangement the dock can be filled and emptied without the use of any extra pumping plant, and at low cost.

NEWS OF THE WEEK

New York, February 6, 1919

Proposed Modifications of the Federal-Aid Road Law

Despite agitation for a more extended road-building program, it is believed by many who are in touch with the situation in Washington that the most that can be obtained from the present Congress is represented by the following clauses inserted in the Post Office Department Appropriation Bill for 1919-20 by the Senate Committee on Post Roads:

Section II of the Federal-aid road law of 1916 is to be modified so that a post road is interpreted to mean any public road which is now used, or may be made suitable, for the transportation of the United States mails, excluding roads through places with a population of 2500 or more where the houses average less than 200 ft. apart.

The amount of Federal aid in the 1916 law is to be increased by $50,000,000 for the current fiscal year, $75,000,000 for 1920, and $75,000,000 for 1921. Honorably discharged soldiers, sailors and marines are to receive preference, other conditions being equal, when labor is hired for the roads on which these additional funds are used.

War material not needed by the War Department but suitable for highway improvement, is to be transferred to the Secretary of Agriculture at the discretion of the Secretary of War, and to be then distributed among the state highway departments for use in Federal-aid road construction and national forest roads, in the same manner as Federal-aid funds are now distributed.

Appropriations of $3,000,000 annually for the fiscal years 1920, 1921 and 1922 are to be made for coöperative or independent construction of roads in the national forests.

Public Service Engineers Reinstated

On Jan. 31 the Board of Estimate of New York City reversed its action in discharging nearly 400 employees of the Public Service Commission. The commission was authorized to reëstablish the roll in force on Dec. 31, and an appropriation was made to maintain this organization for February and March (the rest of the current quarter).

All those discharged, most of whom were engineers, have been reëngaged by the commission, with the exception of some who had taken positions elsewhere. The principal effect of the board's action of Dec. 31 (noted in *Engineering News-Record* of Jan. 9,

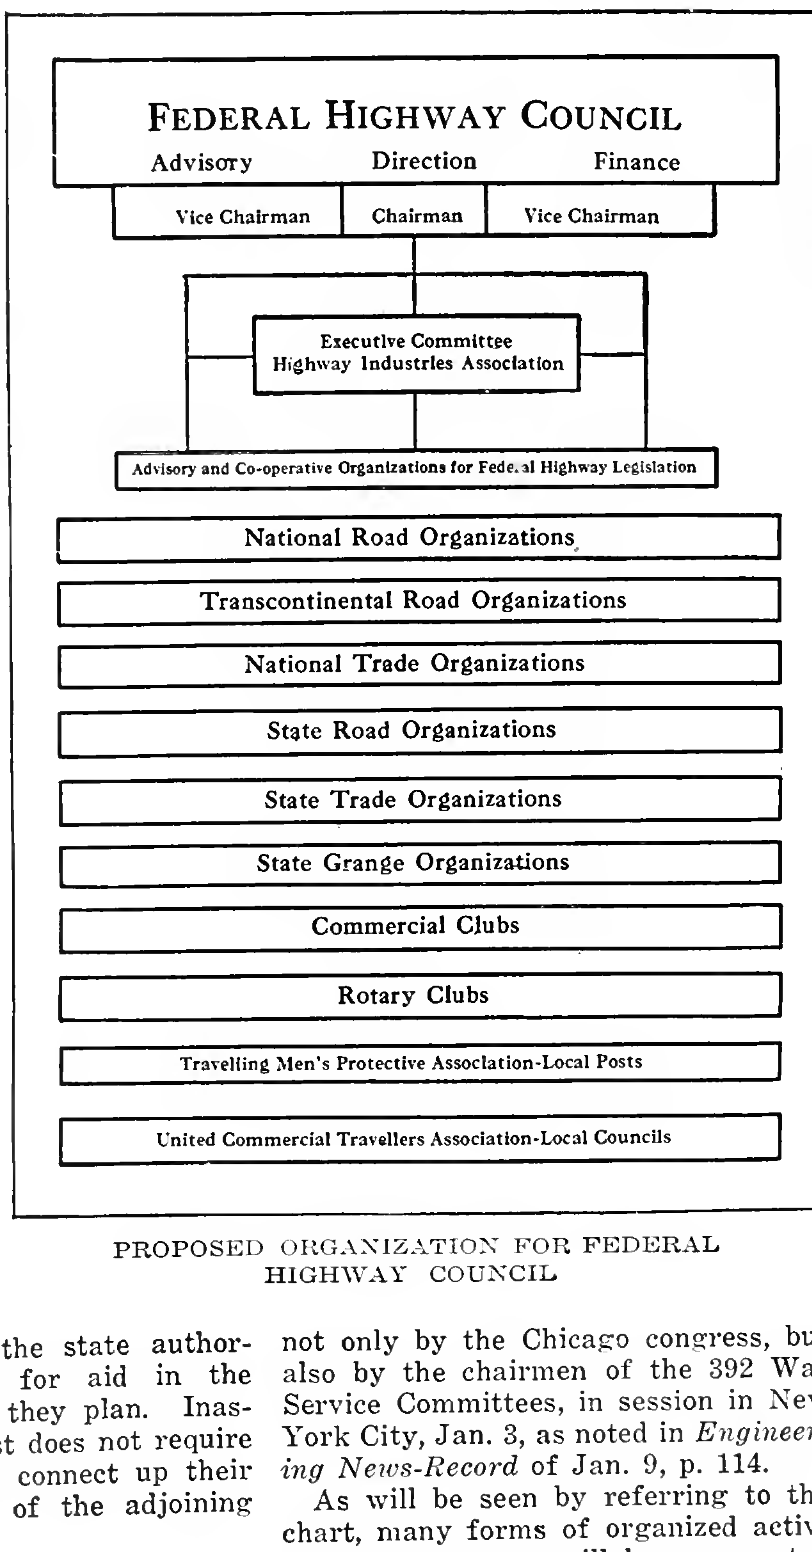
(*Concluded on page* 304)

Large Committee Will Promote Federal Highway Commission and System

Civic Organizations Throughout Country to Coöperate—Highway Industries Association Takes Leading Part

Formation of a Federal Highway Council, as outlined in the accompanying chart, is being arranged in order to promote, crystallize and mobilize sentiment throughout the country for a Federal highway commission to build a Federal highway system. The movement is an outcome of the great highway congress at Chicago last December, and the Highway Industries Association, which, with the American Association of State Highway Officials, called the joint convention, is taking a leading part in the organization of the new movement. It has been realized for some time that the present method of laying out roads under the Federal-aid, state and county plans could never produce anything but a disjointed system. The Bureau of Public Roads has not the power, under the present law, to originate work, but must wait for the state authorities to request it for aid in the road projects which they plan. Inasmuch as local interest does not require it, the states seldom connect up their systems with those of the adjoining states.

To overcome this condition, a Federal highway administration is proposed which will provide for the building of a system distinct from that of the states, while the Federal aid to the states will continue as before. Into the Federal system would be incorporated such present state and county roads as would meet the requirements of the system. Such a plan has been indorsed not only by the Chicago congress, but also by the chairmen of the 392 War Service Committees, in session in New York City, Jan. 3, as noted in *Engineering News-Record* of Jan. 9, p. 114.



PROPOSED ORGANIZATION FOR FEDERAL HIGHWAY COUNCIL

As will be seen by referring to the chart, many forms of organized activity in the country will be represented on the committee. Circular leters containing reports of the action taken by the two conventions were sent to the organizations designated and others, and more than 300 answers have been

received, giving approval and signifying a willingness to coöperate by sending delegates to assist in forming the organization.

The plan is to have one delegate from each national, state and local organization upon the main committee. These will elect the various chairmen, while the Highway Industries Association will act as the executive committee and work through the different members of its local organizations, which will in turn use their efforts to bring before the public in their particular localities the need for a national highway system.

Public Works Department Up at Washington

Congressional Committees Listen to Suggestions from Engineers for Its Formation

(Washington Correspondence)

Last week the long dormant subject of a Federal Department of Public Works became more or less a live issue at Washington. There is no prospect that anything definite will be done in the immediate future, particularly by the present Congress, which goes out of existence on Mar. 4 and which is far behind in its necessary appropriations and other legislative business. It is a fact, however, that the subject has been brought to the attention of at least two Congressional committees and that agitation on the part of a number of individual engineers and of the Engineering Council is in prospect.

Before the Senate Committee on Labor and Agriculture, which is holding hearings on the Kenyon bill providing for an emergency appropriation for public work (noted in *Engineering News-Record* of Jan. 30, 1919, p. 256), some engineers urged to the consideration of Congress the necessity for a department of public works. The Kenyon bill in effect provides an emergency department of public works made up of representatives of various departments, the Chief of Engineers of the United States Army, and two citizens to be appointed by the President. While the bill is supposed to be an emergency measure, it provides that the appointive members shall be designated, one to serve for two years and one for four years, and thereafter each member shall serve for four years, all of which would indicate that emergency in the mind of the author of the bill is not the same as temporary. The bill also provides that money shall be loaned to municipalities, counties and states, by the Federal Government at a rate not less than 5 per cent., to build public works, and that an officer of the Corps of Engineers, U. S. A., has to pass upon the practicability and usefulness of any state or municipal public work for which such an advance is asked. The Chief of Engineers, furthermore, is ordered to coöperate so far as is practicable with the state or local officers having in charge the planning, supervising, directing and executing of any such public work. This, it will be seen, practically puts the control of the emergency public works department in the hands of the Chief of Engineers of the Army.

The other committee before which the subject has been broached is the Senate Committee on Public Buildings and Grounds. In the course of testimony on an entirely different matter, General Marshall of the Construction Division had occasion to refer to the need for a department of public works. This seemed to interest the committee, particularly Senator Hardwick of Georgia, who was acting chairman, and the General, together with some members of his staff, and some representatives of the Engineering Council, which had later discussed the matter, were asked to appear before the committee to give their opinions of the necessity for a department of public works and possibly of a method for its operation. There has been as yet no public indication that the committee intends to bring in any particular bill for a Federal Department of Public Works, but the attitude of the senators who make up the committee and who are interested in Government construction probably more than any other senatorial committee, showed that the present is a live time for conducting among the legislators an educational campaign on the public works department idea.

Employment

For the convenience of engineers returning from military life, and others, there are listed below agencies which may be helpful to those who are seeking employment:

Engineering Societies Employment Bureau; Walter V. Brown, secretary, 29 West 39th St., New York City.

Division of Engineering, United States Employment Service, 29 South La Salle St., Chicago, Ill.

Professional and Special Section, United States Employment Service; George W. Kirchwey, state director, 16 East 42nd St., New York City.

Public Service Engineers Reinstated

(Concluded from page 303)

p. 112) is that the 339 discharged engineers were deprived of a month's pay, and that the rapid-transit construction work was temporarily checked and disorganized. A number of the men discharged remained at work through the month, however, and, according to officials of the commission, this proved of great assistance in carrying on the necessary office and field operations with the depleted force.

Seek Reasonable Motor Truck Requirements

Road Engineers and Manufacturers Consider Speeds, Weights and Sizes at Meeting

A spirit of coöperation marked the meeting of the National Highway Traffic Association at the Automobile Club, New York, Jan. 31, which was called to discuss the weight, size, and speed of motor trucks. In a discussion entered into by both highway engineers and representatives of truck manufacturers, there was evidenced by both sides a distinct desire to compromise on a reasonable basis. Truck limits were discussed in the light of general conditions throughout the country, and a resolution was passed to promote road building as a national undertaking.

In opening the meeting, A. H. Blanchard, president of the Highway Traffic Association, stated its purpose and announced that after hearing a few set speakers the meeting would be open for general discussion. Before opening the meeting he offered a resolution favoring a national highway commission, a national system of good roads, and greatly increased Federal aid. The resolution was unanimously carried.

George H. Pride, chairman of the Committee on Motor-Truck Regulation, the first speaker, dealt with the necessity of coöperation between the interested parties. As trucks are eminently utilitarian they must be fostered for the benefit of the country, which means the use of trucks of reasonable dimensions on adequate roads.

Since no set of figures can settle the proper thickness of road crusts, an arbitrary limit must be placed on the trucks until such time as experience supplies a working basis, according to W. G. Thompson, state highway engineer of New Jersey. Mr. Thompson maintained that at present highway design necessarily rests upon empirical rules, as there are so many unknown quantities. After pointing to the great increase in truck traffic and stating that New Jersey has as much as any state, he suggested the figures recommended by George M. Graham at the Chicago congress as a basis to start discussion. These call for a maximum truck load of 28,000 pounds. See *Engineering News-Record* of Dec. 19, 1918, p. 1109.)

Charles G. Bond, counsel for the Motor Truck Association of America, decried the tendency to include too many details in uniform traffic laws. He felt that details should be left to the local officials and that emphasis should be put on simplicity. In his opinion, the law should be limited to the regulation of dimensions, weights and speeds, leaving out such details as license fees, etc. Otherwise, there will be no possibility of getting the law adopted generally. He cited the New York State Constitution submitted a few years ago, which had so many details that everyone had something against it.

General conditions as they affect the problem were set forth by E. W. James, general inspector, Bureau of Public Roads. He gave statistics to show that the great porportion of roads receiving Federal aid are of types from ordinary earth up to water-bound macadam. Six-ton gross loads for bridges are about the largest that can be obtained in many states, according to Mr. James. From this he argued that before you can pass a uniform traffic law throughout the country you must secure uniform construction details. He believes that the truck of five-ton capacity is the heaviest feasible at present, and even this weight could not be borne by a large portion of the roads.

In arguing for a great campaign of education for the public, A. D. Williams, the retiring highway commissioner of West Virginia, stated that it was his belief that the United States should spend $20,000,000,000 for roads in the next few years. In answer to general discussion favoring unlimited motor-truck expansion, he said that the engineers stood ready to build roads which would bear any load, if the money is provided. Their greatest trouble is financial.

Charles M. Upham, chief engineer, Delaware Highway Commission, made a plea for definite assurance as to the maximum loads of the future, so that the engineer would have a standard to work with. Discussion brought out in this connection that the 28,000-lb. load suggested by George M. Graham is about the maximum that rubber tires will stand.

In closing the meeting, President Blanchard announced that a progress report of the Motor-Truck Regulation Committee will be made at a joint meeting with the American Road Builders' Association at its convention to be held in New York City Feb. 25-28.

Bridge Committee Discusses Road Crossings Over Large Rivers

Unification of bridge and road control under the same Governmental authority was advocated at the organizing meeting of the Division of Bridges, National Highways Association, held recently at New York. A resolution was passed expressing the opinion of the division that construction and maintenance of bridges should in general be in the hands of the same Governmental unit that builds and maintains the adjoining roads.

Active discussion developed on the subject of the present seriously inadequate provision for highway crossings over large streams, especially those forming state boundaries. Such instances were cited as the absence of all highway crossing over the Mississippi south of Memphis and over the Hudson south of Albany, and the existence of only three highway bridges across the Missouri within the State of Missouri, a length of 350 miles. The chairman pointed out the feasibility of adding a highway floor to a railway bridge at the time of its construction, and the meeting decided to promote all efforts of local authorities to obtain the construction of such joint bridges.

Recognizing the value of the work in improving bridges done by the various state highway departments, the meeting took note of the lack of similar care for problems of interstate river crossings, and resolved to coöperate in working out the problems of such crossings, when requested. The desirability of uniform requirements for bridges throughout the country was also discussed.

Another meeting of the division is to be held within 30 days. The members are: Chairman, Gustav Lindenthal, New York; Admiral H. H. Rousseau, Washington; Prof. George F. Swain, Boston; Frank C. Osborn, Cleveland; Prof. E. J. McCaustland, University of Missouri; Prof. Donald Derickson, Tulane University; Edward Duryea, San Francisco; R. D. McCarter, New York; F. E. Schmitt, New York; and Charles Evan Fowler, 25 Church St., New York City, secretary.

Illinois Engineers Will Assist In Legislation

Many General Measures for Regulation Indorsed by State Society at Bloomington Meeting

That state legislation is a means of promoting progress in engineering and technical development, is evidently the opinion of the members of the Illinois Society of Engineers, who attended the 34th annual meeting, held at Blooming-for Jan. 29-30. They indorsed measures for regulating vehicle loads and speeds, regulating housing conditions, promoting drainage and land reclamation, regulating the operation of sewage- and water-treatment plants, regulating the practice of engineering, and expediting the preparation of topographic maps of the country. Besides appointing a legislative committee, they arranged for engineering participation in the revision of the state constitution. They advocated the construction of municipal improvements and other public work as aiding in the solution of the problems of the reconstruction period, urged adequate salaries for school teachers, and also the lowering rather than the raising of railway rates on materials of construction.

Need of a state law to regulate housing conditions in order to promote health and vitality, to prevent disease and to protect the community, was presented in a paper by Charles B. Ball, of the Chicago Health Department. The housing bill now before the legislature was outlined by Senator Kessinger. As it appears that this applies to new structures, the suggestion was made that it should include the remedy or removal of existing unsanitary conditions. The engineer's part in the after-the-war reconstruction problems was reviewed by Prof. F. H. Newell, of the University of Illinois, while W. D. Gerber, of Chicago, reviewed the possibilities of engineering coöperation.

Prevailing unsanitary conditions of sewage-treatment plants was shown in a paper by M. C. Sjoblom, assistant engineer of the state Board of Health. These are due partly to ignorance and lack of understanding, but largely to neglect, plain and simple. As a remedy, Mr. Matte, chief engineer, presented a draft of a law giving to the board power to compel the abatement of nuisances and dangerous conditions, and also power to compel the employment of competent operators at both water- and sewage-treatment plants. The city water-supply system of Bloomington was described by C. D. Williams, superintendent, and a visit was paid to the pumping station, where a new concrete-lined well is being sunk.

Flexible paving for country roads, in the form of brick on gravel, macadam or lean concrete, was advocated by G. H. Reiter, of the Illinois Paving-Brick Bureau. A talk by Clifford Older, state highway engineer, on the program for road work under the Illinois $60,000,000 bond issue, produced a rapid-fire attack of questions concerning what work is to be done, and where and how.

Regulation of wheel loads and speeds on country highways was suggested in a report by J. G. Gabelman, of Chicago, as follows: Three-ton vehicles with pneumatic tires, 25 miles per hour; three to six tons, 20 and 15 miles per hour with pneumatic and solid tires; six to twelve tons, 16 and 12 miles per hour; 12 tons to maximum load, nine miles per hour; maximum wheel load to be five tons, with not more than 800 lb. per inch of tire in contact with the road; all steel-tired vehicles to be limited to six miles per hour. Formulas for regulating speeds of trucks were suggested by H. J. Fixmer, of Chicago, who also showed a new form of parabolic cross-section for streets.

Inland navigation as a possible accessory to river improvements was suggested by Prof. F. H. Newell in a paper on the water resources of Illinois, but he pointed out that the unknown factor is the economic feasibility; that is, whether the waterways would be used to such an extent or in such a way as to justify their cost.

Officers for 1919 were elected as follows: President, J. W. Dappert, drainage engineer; vice-president, F. W. DeWolf, Illinois Geological Survey; secretary, E. E. R. Tratman, Wheaton, Ill. The next meeting is to be held at the University of Illinois, Urbana, Ill.

Bowles To Leave Fleet Corporation

Announcement of the resignation of Francis T. Bowles from the position of assistant general manager of the Emergency Fleet Corporation was made by the Shipping Board Feb. 3. The resignation, tendered Jan. 25, is to take effect Mar. 15.

Proposed Raise of Rates Threatens Construction

Chicago Meeting Protests Against Increase on Sand, Gravel, Crushed Stone, and Slag

Road building will be seriously curtailed, and general construction will be retarded, if the increase in freight rates proposed by the Railroad Administration on sand, gravel, crushed stone and slag are put into effect—this was the opinion of state highway officials, producers and industrial associations voiced at a hearing held in Chicago Jan. 30, before the Central District Freight Traffic Committee. About 400 representatives of the industries affected by the proposed rate action attended the hearing.

The increase proposed is on a mileage scale, with excess for two-line hauls. The territory affected is roughly that south of the Great Lakes and north of the Ohio River and extending east from the Illinois-Indiana state line to include the western part of Pennsylvania.

Calls Proposed Rate Absurd

According to H. C. Barlow, who represented the Chicago Association of Commerce, with the present Federal direction of railways there is logically no such thing as a two-line haul, and the increased rate proposed over single-line haul is an absurdity. He said that present rates are excessive and unjust; they should be reduced and not increased. Other speakers condemned the mileage scale as a basis for fixing rates. Producers had established their plants and built up their markets on the old rate-making basis, and the change to a mileage scale would disorganize everything accomplished. Figures were presented by large producers showing that the new scale would increase the cost of shipments to their regular markets from 10 to 150 per cent. In some instances, it was asserted, the increase would completely exclude the producer from his best markets and might even force him to discontinue business.

Commissioner S. E. Bradt said that Illinois planned to spend $60,000,000 on about 4800 miles of hard roads, and if the increase under discussion went through, Governor Lowden would hesitate a long time before authorizing construction. To ship a ton from Janesville to Park Ridge, a distance of 98 miles, the price was 30c. until last June, when it was raised to 50c. and now it is proposed to make it 95c. Mr. Bradt continued:

"You can figure out how much that means in road construction when you estimate that 6000 tons must be used to each mile. With the increase in rates last June the cost of the Illinois road program was raised from $60,000,000 to $64,000,000. This proposed raise adds at least $4,000,000 more.

"Take a ton carried from Joliet to Springfield, 148 miles. The cost was 53c. until June, then 70c., and now it is proposed to make it $1.20. Another illustration is from Racine to Evanston, 52 miles. The increase was from 40c. to 60c. last June, and the proposal is for 85 cents."

The people of Michigan, according to J. H. Bateman, assistant commissioner, will be asked to vote at the spring elections on a $50,000,000 bond issue for good roads. It is planned during 1919 to spend $6,000,000. On the basis of the new rates, freight on a mile of 16-ft. gravel road will amount to $4000 and on a mile of 18 ft. concrete road it will amount to $5200. Quoting the specific example of the Detroit-Monroe road built last year, Mr. Bateman said: "The freight on the sand and gravel for this job cost $2400 a mile before June, 1918, when the cost was increased to $3200, and now it is proposed to make it $5200." If these higher rates were put in force it would he said, gravely, affect the disposition of the people of Michigan to enter on a broad policy of road improvement.

Resolutions of protest were formally presented by delegates from the legislatures of Ohio, Indiana and Michigan. The Ohio resolution, whch is typical of the others, respectfully but most urgently requests the President of the United States, Congress and the Railroad Administration to take such action as will immediately and effectively prevent an upward revision in the freight rates upon materials entering into the construction of public works.

"This proposition will throw a wet blanket over construction of public works," said John M. Glenn of the Illinois Manufacturers' Association. "Instead of encouraging activity, it will discourage it. The proposal is a serious error."

Other speakers were Dale F. Stansbury, assistant attorney general of Indiana; O. P. Gothlin, of the Indiana Public Service Commission, and B. F. Affleck, representing the National Federation of Construction Industries.

Michigan Engineers Suggest State Board of Public Works

Establishment of a state board of public works, affiliation of technical societies, and the passage of an engineers' licensing law, were all indorsed by the Michigan Engineering Society at its fortieth annual meeting, held in Flint, Jan. 21-23. About 120 members and visitors were registered. In connection with the encouragement of drainage projects a central authority was suggested. The suggestion developed into the idea of state supervision and assistance of public works in general. A resolution was adopted for the appointment of a committee to consider whether such a plan is advisable, and how it can be carried into effect.

C. E. Drayer, secretary of the American Association of Engineers, discussed the advisability of close coöperation of engineers and engineering societies. This led to a general discussion, which ended in the appointment of a committee to consider the coöperation or affiliation of all technical societies in Michigan.

A licensing law for civil engineers was submitted by a committee and approved, with some minor changes. The committee was then directed to have the bill presented to the legislature. The suggestion was made that the bill ought to apply to engineers in general, but the majority opposed it.

Prof. H. H. Atwell suggested changes in the present cumbersome drainage laws, including means for making the credit of the state available for large projects so that the cost could be spread over several years. He estimated that Michigan has 4,000,000 acres of land awaiting drainage. Reconstruction of small water-power plants was discussed by H. K. Holland. He referred especially to plants of 8- to 20-ft. head and 100 to 500 square miles of drainage area. Municipal work by day labor was described by E. C. Shoecraft, city engineer, Flint, Mich., where all sewer, paving and sidewalk work is done by the city forces, also the cleaning of streets. He said the results have been highly satisfactory. Sanitation in a military camp was the subject of a talk by the president, Maj. E. D. Rich, late director of the school of sanitary engineering at Camp Greenleaf, and limitations in the use of chlorine for water treatment were discussed by W. C. Hirn, assistant state sanitary engineer. Duties of the county engineer as both engineer and manager were outlined by E. E. Sours, who said that at present 31 counties in Michigan, where they act more or less as county managers, are employing county engineers on salary.

Delegation to France Returns and Will Address Engineers

The delegation of American engineers which sailed from New York Dec. 5 to attend the joint engineering congress in Paris, France (see *Engineering News-Record* of Nov. 28, 1918, p. 1003) returned Jan. 31, with the exception of the chairman, Maj. J. F. Case, who went to Italy. All members of the four national societies are invited to attend a meeting in the Engineering Societies' Building, New York, Monday evening, Feb. 10, when the delegates will describe informally the work of the congress and their impressions of conditions in France.

New Bills In Congress for Federal Aid to Hudson River Tunnel

Bills have been introduced in both houses of Congress, by Senator Calder of New York and Representative Eagan of New Jersey, for Federal participation in the construction of a vehicle tunnel under the Hudson River between New York and Jersey City. The Senate bill, offered as an amendment to the Post Office appropriation bill, would direct the Secretary of Agriculture to join equally with the two

states concerned in building the tunnel as a post route; the maximum participation is fixed at $6,000,000, and the sum is to be repaid from tolls collected from the traffic through the tunnel.

Indiana Engineers Seek License Law With Architects

State Body Holds Joint Meetings with Several Local and National Sections —Watches Proposed Road Laws

Good roads construction and cost-keeping, lessons from the war, the engineer's economic welfare, and license legislation largely occupied the attention of the hundred engineers attending the thirty-ninth annual convention of the Indiana Engineering Society, held Jan. 23-25 in Indianapolis. Coöperation with local engineering organizations was well worked out. Immediately prior to the first session, a dinner meeting was held by the Scientech Club, the reorganized Indianapolis Engineers' Club. An evening session was held jointly with the American Association of Engineers, and at another meeting the local section of the American Society of Mechanical Engineers participated. The annual dinner was also held jointly with the local sections of the national societies, and the Scientech Club.

Indiana's delay in its state highway work, due to the slowness with which the courts decided its state commission to be constitutional, means that more legislation is being considered. The engineers have a legislative committee carefully watching developments to insure, if possible, a practical working plan.

M. T. Calef, highway engineer, South Bend, exhibited a careful analysis of methods of unit-cost keeping, based on all factors and spread out over a 20-year period. Prof. R. P. Wiley, in a paper on "The Rational Method of Estimating Storm Water Run-off," gave essential points in sewer design, saying that the engineer's judgment is of far more importance than generally given credit. Camp sanitation at Camp Custer, as described by S. A. Greeley, indicated that during construction the strict regulations and attention to cleanliness and personal hygiene of the men had kept the influenza from gaining any headway. Knowledge of this fact enabled the contractor to maintain a full working force and attract all the labor he needed when other contractors were unable to keep a full force.

Prof. D. D. Ewing's paper, "Electrically Driven Pumps in Small Water-Works," included concrete examples of power requirements, costs and comparisons, and gives valuable reference data.

Public-utility problems were handled in six papers, four of which were on the fuel question and war experiences.

C. E. Drayer, secretary of the American Association of Engineers, spoke at the joint meeting on "Local and National Societies Coördinated," and W. W. DeBerard was substituted for W. H. Finley, president of the Chicago & Northwestern Railway Co., who was scheduled to talk on "The Relation of the Engineer to Social and Business Problems."

H. O. Garman discussed the proposed structural engineers' and architects' bill. In effect, this will require all civil engineers to apply for license. Initial registration for a six-months' period will cost $30, but subsequent licensing by examination will cost $50, and annual renewals $10. Danger of the Illinois controversy with the architects is avoided by putting the two professions together with separate licenses for each. Penalties range from $10 to $500 in fines. Concurrent with the bill is one proposed by the county surveyors' organization for the creation of a new office, that of county engineer, with proper qualifications and with salaries, based on populations, ranging from $1800 to $4500. It is hoped to raise the standard of the county surveyor, who is now an elective statutory official without other qualifications than being a voter, by providing that the county engineer be the surveyor if the latter is qualified for the engineer's position.

The society is supporting both bills, and also instructed its legislative committee to prepare one, on civil service for municipalities, which the business men of the state Chamber of Commerce requested that the society write and present. Prof. G. A. Young was elected president, Charles Cheney, vice-president, and Charles Brossmann secretary-treasurer.

Labor Department Will Take Up Safety Code Work

The Working Conditions Service, Department of Labor, announces in connection with its plans for safety work during the coming year that the following codes, among others, will be first taken up, with the coöperation of the Bureau of Standards, Department of Commerce:

Plant arrangement, including routing of material and product, design of buildings and layout of plant; yard entrance and exit gates, roadways and walkways, railroad tracks, material piles, clearances and illuminations; fire hazards, including fire-fighting equipment, water mains and hydrants; spacing between buildings as related to occupancy, and arrangement of yard material as related to occupancy of buildings.

Building equipment, including stairs and exits, skylights, ladders, railings, and toeboards (fixed), platforms and scaffoldings (fixed), illumination and window cleaning.

Fire prevention and protection.

Elevators, including shaftways and hatchways, shaftway equipment, cables, counterweights, guide rails and bumpers, landings, landing doors and gates, cars and car construction, machines, machinery and machine rooms, car and machine safety devices, control and signals, and escalators.

Cranes and derricks, including controllers and wiring, hoist mechanism and brakes, clearances, bridge, tower and gantry cranes, locomotive cranes and derricks, and hand-power cranes.

Conveyors and conveying machinery.

Head and eye protection, including protectors for chippers, riveters, calkers, for babbitting and similar operations, sealing, grinding and similar operations, dipping and brush coatings, sandblasting, oxyacetylene welding and furnace work, and electric-arc welding and cutting.

Lumber and wood-working machinery.

Organize the National Merchant Marine Association

As a result of the American Merchant Marine conference at Washington, Jan. 22-23, a new organization was created, to be known as the National Merchant Marine Association. Its purpose will be to carry on a nation-wide propaganda in advocacy of a large American merchant marine. R. Goodwyn Rhett, former president of the Chamber of Commerce of the United States, was elected chairman, and Winthrop L. Marvin, of Boston, secretary. The governing body of the organization will consist of the officers and a council of not less than 30 members, the nucleus of which will be members of the resolutions committee which recommended the creation of the new organization.

Strong opposition was made to the report of the resolutions committee by Rear Admiral Francis T. Bowles, in charge of the Emergency Fleet Corporation at Hog Island, who contended that the interests of the various parties engaged in shipping were well represented by the American Steamship Association. He said that he was of the opinion that it was inappropriate to attempt the organization of any body representing private interests when the nation's interests were at stake.

Assurance that the United States Navy would lend every aid to the new organization was made by Commander Charles Belknap, U. S. N., who stated that the Navy should train the men and officers of the merchant marine, and that they should then be made members of the Naval Reserve. J. J. Powell, vice-president of the Bethlehem Shipbuilding Corporation, said that the cost of building American ships was a barrier against any attempt to establish a merchant marine, unless the nation assumed the undertaking; the difference between the cost of a ship in Great Britain and that of one in this country was now $100 per ton, an increase from about $25 or $35 a ton before the war. A great part of this cost, he said, was due to the increase of the cost of labor.

Among the members of the resolu-

tions committee named by Chairman Ransdell were H. A. Wheeler, president of the United States Chamber of Commerce; P. A. S. Franklin, president of the International Mercantile Marine; J. H. Pruitt, president of the Masters', Mates' and Pilots' Association; F. L. Sanford, of the Southern Pine Association, and C. E. Grunsky, of San Francisco. J. Parker Kirlin, of New York, headed the committee on organization.

A. S. Baldwin President Western Society of Engineers

A. S. Baldwin, vice president of the Illinois Central R.R., has been elected president of the Western Society of Engineers. He was born at Winchester, Va., in 1861, and began his career as a railway engineer in 1879. After 14 years of service with the Louisville & Nashville R.R., he entered the employ of the Illinois Central R.R. in 1907 as principal assistant engineer. He was made chief engineer in 1905 and in 1918 he was made vice president. He was president of the American Railway Engineering Association in 1917. As a member of the Western Society of Engineers he has taken special interest in its development and in the management of its finances.

Public Service Commission Reports on Past Year

Rapid-transit lines aggregating 63 additional track-miles were opened to traffic in New York City during 1918, according to the annual report of the Public Service Commission for the First District, New York, and it is said that the end of the current year will see placed in operation 300 of the 341 track-miles of the system remaining to be completed. It is promised that early in 1920 the entire work will be practically finished. Since Jan. 1, 1918, the Interborough and the Brooklyn Rapid Transit Companies have spent a total of $48,000,000 for construction and equipment of new lines, while the city for construction alone has spent $19,000,000, in addition to $358,600 for improvements to the first subway.

It is stated that if the Board of Estimate will coöperate in granting the necessary funds, more than $20,000,000 of the remaining $25,000,000 worth of new work yet to be done can be let before the end of the coming summer. Under outstanding contracts there is upward of $20,000,000 worth of work, contract value, yet to be done to allow $80,000,000 of new lines to be placed in operation.

The report says that the gross increase in traffic on the city transportation lines during the past year was 56,670,090, which represents per capita riding of five more rides per person than in 1917. The total amount paid to the companies in fares was $97,394,225, an increase of $2,843,309, or 3 per cent over the preceding year.

Now that the war is over, the commission believes that the grade-crossing elimination work should be actively resumed, and the legislature is asked to appropriate $250,000 as the one-quarter share of the state toward $1,000,000 which is considered necessary.

At the end of 1918 the employees of the commission, including over 400 absent on war duty, numbered 1651, as against 1855 at the close of 1917.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN ROAD BUILDERS' ASSOCIATION; 150 Nassau St., New York City; Feb. 25-28, New York City.

AMERICAN INSTITUTE OF MINING ENGINEERS; 29 West 39th St., New York City; Feb. 17-20, New York.

The Engineers' Club of Dayton, Ohio, was addressed Jan. 21 by Worcester R. Warner, vice-president of the Warner & Swasey Co., Cleveland, who delivered an illustrated lecture on Egypt and the pyramids. The first anniversary banquet, celebrating the dedication of the new clubhouse of the club, the gift of E. A. Deeds and F. C. Kettering, will be held Feb. 4. Representatives of all the national engineering societies will be present, and the subject of the furtherance of engineering coöperation will be discussed.

The Engineers' Club of Boston, Mass., celebrated its sixth anniversary, Jan. 23, at the clubhouse. Originally the resident membership of the club was limited to 500 and the nonresident to 200. The limit is now 750 resident and 300 nonresident, and there are 603 resident members and 287 nonresident, besides the 16 life members and four Army and Navy members.

The Hamilton, Ont., Branch of the Engineering Institute of Canada held a meeting Jan. 17 at which the subject of legislation in relation to the engineering profession was discussed. It was decided that since many Governmental questions, especially those dealt with by various commissions, are essentially engineering questions, the Engineering Institute should endeavor to obtain representation on such commissions, where the presence of one or more professional engineers is appropriate.

The New York City Chapter of the American Association of Engineers will hold an open meeting of New York engineers at the Machinery Club, 30 Church St., Feb. 10. W. H. Finley, president of the American Association of Engineers, will speak on "Engineering Organization and its Relation to Public Service." The meeting will be preceded by a dinner.

The Binghamton, N. Y., Engineering Society, at the annual meeting held Jan. 28, elected the following officers: President, C. E. Anderson, vice-presidents, Charles Van Amburgh, Burt E. Nelson and G. Fred Scharbach; secretary, D. M. Edgerton; treasurer, Frank J. Tillman; librarian, C. E. Beach.

The Houston, Tex., Engineers' Club held its regular monthly meeting Jan. 23. James Z. George, general manager of the Houston Chamber of Commerce, spoke on "The Opportunity and Responsibility of the Engineer in the Readjustment Period."

The Engineers' Club of Philadelphia, at its luncheon Feb. 11, will be addressed by Dr. William D. Lewis, principal of the William Penn High School, on "What the War Has Taught Us About the Educational Needs of Democracy."

The Manitoba Branch of the Engineering Institute of Canada, meeting at Winnipeg Jan. 20, decided that a close watch should be kept on all public works, provincial and Federal, which involve engineering problems. Among the matters discussed at the meeting were the development of national resources, highways, and drainage.

The Engineering Institute of Canada on Jan. 28 held, at the headquarters in Montreal, the preliminary session of the annual meeting.

The Utah Society of Engineers held a meeting in Salt Lake City Jan. 15, at which the initial steps were taken in a movement to consolidate all the engineering societies in Utah into one body, to be known as the Associated Engineers of Utah. The new society will comprise the Utah Society of Engineers and all other organizations of mining, civil, electrical, mechanical, and chemical engineers in the state. The recent meeting is an outcome of the one held Oct. 16, at which the proposition for the consolidation was put before the Utah Society, and a committee consisting of G. M. Bacon, H. T. Plumb, and Ernest Gayford was appointed to consider the matter. The committee has conferred with representatives of national engineering bodies and has proposed changes in the constitution of the Utah Society of Engineers which will permit that body to become the affiliating medium for all similar organizations.

The Montreal Branch of the Engineering Institute of Canada, at its regular meeting, Feb. 20, will be addressed by J. L. Busfield, whose subject will be "The Construction of the Canadian Northern Railway Tunnel, Montreal."

The Engineers' Society of Northwestern Pennsylvania, the Erie Chapter of the American Institute of Electrical Engineers, and the Erie Chapter of the American Society of Mechanical Engineers (Associated Bodies) will hold a joint meeting Feb. 11 in Erie. The lecturer of the evening will be Prof. Comfort A. Adams. His subject will be

"Arc Welding as Applied to Shipbuilding."

The Duluth Engineers' Club, at its meeting Jan. 27, decided to support energetically the project for a deep waterway from the Great Lakes to the Atlantic. Frank Hutchinson, Dwight E. Woodbridge and W. H. Woodbury were appointed a committee to obtain information. E. R. Lewis was elected to represent the club on the Minnesota State Joint Engineering board. Besides the regular representative, the Duluth club will be represented by two special delegates, Dwight E. Woodbridge and J. L. Pickles, at the annual meeting of the joint board, to be held at St. Paul on Feb. 12-14. A committee of the club was named to investigate prices of cement, at the suggestion of the Minneapolis Engineers' Club, that existing prices are too high under peace conditions.

The American Water-Works Association will hold its 39th annual convention in Buffalo, N. Y., June 10-14. The headquarters of the convention will be the Hotel Iroquois.

The San Francisco Chapter of the American Association of Engineers was tentatively organized Jan. 24, when 10 members of the association and six applicants met for the purpose of organizing the local chapter, discussing means for extending the influence of the organization and instituting a campaign for new members. A petition to the Board of Directors in Chicago for a charter for the chapter was drawn up and signed by all present, and a total of 20 signatures from California members was anticipated at an early date. J. H. Knowles was elected temporary chairman and A. G. Mott temporary secretary and treasurer.

The San Francisco Section of the American Society of Mechanical Engineers, the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Institute of Electrical Engineers and the American Chemical Society held a joint meeting Jan. 24 under the auspices of the electrical engineers, at the Engineers' Club. The subject of the evening was "A Symposium on Engineering Education," and 15-min. talks were made by J. W. Beckman, representing the chemical engineers; John A. Britton, the mechanical engineers; C. L. Cory, the electrical engineers; C. D. Marx, the civil engineers, and T. A. Rickard, the mining engineers. A considerable number of those present participated in the discussion. There was rather general agreement as to essentials, which were that a most important function of the college course for the engineer is to equip him so that he will be able to take a broad view of the problems he meets later. It was considered that a grounding in fundamentals is more important than endeavoring to fit a man for some specialty.

The Tacoma Master Builders' Association, Tacoma, Wash., recently held its annual meeting, at which the following officers were elected: S. C. Erickson, president, for another term; John Biehn, vice-president; A. L. Sutterfield, secretary; Dick Ketner, treasurer.

The Engineers' Club of Seattle has established a clearing house for obtaining positions for returned soldiers or sailors who were formerly connected with the engineering profession. E. J. Bartells, secretary, is in charge of the work.

The Associated Engineering Societies of Seattle held a joint meeting Jan. 24 at Bagley Hall, University of Washington. The features of the program were furnished by the Puget Sound section of the American Chemical Society and the Seattle Association of Members of the American Society of Civil Engineers. John L. Hall, president of the Pacific Northwest Society of Engineers, spoke on "Engineering Education."

The American Institute of Mining Engineers will hold its 119th meeting in New York during the week of Feb. 17. Members of the Canadian Mining Institute, the National Research Council and the American Institute of Electrical Engineers will join the mining engineers in their discussions.

The Topeka Engineers' Club was organized Jan. 25 at Topeka, Kan. Sixty men, residents of Topeka, were present, representing all branches of the engineering profession. The officers for the present year are: President, John Williams; secretary, Lloyd B. Smith.

Personal Notes

Readers who are returning to civil life from military, naval or other Government service are strongly urged to send in items about themselves and about their friends who are in similar situation. Items should give former position, describe character of military or other service and state the civil work to which the engineer or contractor in question is going. In the case of those with service abroad, information regarding the activities of the units to which they were assigned is especially desired.

COL. CURTISS SHOTWELL has been appointed engineer of the Third Mississippi River District, in succession to A. M. Todd.

A. D. WILLIAMS, chairman of the West Virginia State Roads Commission, has resigned in order to devote more attention to his personal business. His successor is Maj. C. P. Fourtney, as noted elsewhere.

RAYMOND BAFFREY, president of the Hennebique Construction Co., New York, and a captain of artillery in the French army, has been made a Chevalier of the Legion of Honor by the French Government. He had previously been decorated with the Croix de Guerre. Captain Baffrey left New York for France in 1914, served three years on the western front, was cited twice for valor, and was seriously wounded in Flanders in 1917. After recuperating in this country he was assigned to service with the French High Commission in New York.

MAJ. EDWARD J. LANGFORD, Engineers, U. S. A., who has been district engineer in France of the Army transportation service, with headquarters at Marseilles, has been discharged from the service and has returned to his home in Mount Vernon, N. Y. Before entering the Army he was chief engineer of the New York, Westchester & Boston Railway.

HARVEY S. OWEN, formerly engineer of construction and principal assistant engineer to the chief engineer of construction, St. Louis Board of Public Service, has joined the staff of the Lime Association, Washington, D. C., as western district engineer of the Construction Bureau, with headquarters in St. Louis.

THOMAS D. MCINERNEY, recently of the engineering staff of the ordnance department, U. S. A., at the Watertown arsenal, and the Bethlehem Shipbuilding Corporation's Fore River plant, Quincy, Mass., has opened an office for the practice of civil, mechanical and electrical engineering at 99 Chauncy St., Boston, Mass.

MAJ. C. P. FOURTNEY has been appointed chairman of the West Virginia State Roads Commission, succeeding A. D. Williams, who has resigned, as noted elsewhere. He has had extensive experience in highway construction, in this country and in the Canal Zone at Panama.

O. P. M. GOSS and R. H. RAWSON announce the establishment of the firm of Goss & Rawson, consulting engineers, with offices in the Yeon Bldg., Portland, Ore., and in the White Bldg., Seattle, Wash. Mr. Goss was formerly consulting engineer for the Association of Creosoting Companies of the Pacific Coast and for the West Coast Lumber Manufacturers' Association. During 1918 Messrs. Goss and Rawson had charge of the kiln drying of lumber at the Spruce Production cut-up plant at Vancouver, Wash. Previous to that Mr. Rawson was for six years in charge of the St. Helen's creosoting plant. The new firm will undertake investigations and reports on kiln drying plants, or the design or remodeling of such plants.

LEWIS S. SADLER of York County, Pennsylvania, has been appointed State Highway Commissioner of Pennsylvania, succeeding J. Denny O'Neil.

RONALD G. STARR, of Toronto, has been appointed engineer of the Orillia, Ont., electrical and water-works plants, in succession to the late W. K. Greenwood.

H. T. ROUTLY, head of the Routly Construction Co., Toronto, has been appointed by the Ontario Government construction engineer for the Provincial Highway, of which 100 miles will be built this season.

MAJ. JOHN F. OSBORN, 101st Engineers, formerly of the staff of Charles T. Main, Boston, has been detached from the regiment and is now working for the American Commission to Negotiate Peace, directly under Maj. Dugald C. Jackson, in estimating the damages that have been done during the war to French textile mills. His headquarters are in Paris, but he is engaged in inspection tours all along the former war front.

CAPT. C. E. HICKOK, until Jan. 1 attached to the office of the Chief of Engineers, U. S. A., Washington, D. C., has returned to his former position as city engineer of Alameda, Cal. Captain Hickok has been appointed a member of the board of engineers investigating an additional water-supply for the cities of the East Bay District, consisting of Oakland, Alameda, Berkeley and Richmond.

MAJ. E. M. GRAVES, 529th Engineers, who recently returned from France, has received his discharge from the Army and has resumed his duties as president of the Central Dredging Co., Cleveland, Ohio.

WILLIAM S. EVANS, until recently assistant to the resident engineer in charge of construction work, for the E. I. du Pont de Nemours Co. at its dye-works plant at Carney's Point, N. J., is now at Copperhill, Tenn., as engineer with the Tennessee Copper Company.

JOHN W. ALVORD, of the firm of Alvord & Burdick, Chicago, has resigned his position as chief engineer and member of the board of directors of the United States Housing Corporation of the Department of Labor at Washington, effective Feb. 1, and will return to his engineering practice in Chicago. Mr. Alvord has devoted nearly a year of service in organizing the Engineering Division of the Housing Corporation and serving on its board of directors for war emergency work.

T. C. MITCHELL, formerly junior engineer, United States Engineer Office at Great Bridge, Va., who in 1916 went to Liberia to represent the Liberian Government on the Franco-Liberian Boundary Commission, and who returned to the United States to serve in the Army during the war, will soon return again to Liberia to resume his work there. The war prevented the sending by the French Government of an engineer to coöperate with Mr. Mitchell, acting as the representative of Liberia, in delimiting the boundaries between the French possessions and the Liberian Republic.

G. H. KNUTSON, who for the past eight years has been a partner in the Fargo Engineering Co., consulting engineers, Jackson, Mich., is now associated with the Corporation Department of the Harris Trust and Savings Bank of Chicago.

CAPT. THOMAS F. BOWE, Quartermaster Corps, Construction Division, U. S. A., has been appointed Chief of Engineers, Port Utilities Office, at Newport News, Va.

MAJ. O. C. F. RANDOLPH, who received his discharge from the United States Army Engineering Corps Dec. 13, has taken charge of the sale of buildings to railways for the H. K. Ferguson Co., Cleveland. Major Randolph is a graduate of the University of Illinois, and since leaving the university has been in the bridge department of the Michigan Central R.R., and with the Timken Detroit Axle Co. as construction engineer. He was also for a time the construction superintendent for the Austin Co. He left that company to join the Army in July, 1917, as second lieutenant in the Sixteenth Railway Engineers. In France he was in charge of building work at Is-sur-Tille, some of which work was described in *Engineering News-Record* of July 4, 1918, p. 27. When the armistice was signed Major Randolph was in this country organizing a sapper regiment to return to France.

PAUL E. GREEN, district engineer of the Bureau of Industrial Housing and Transportation, has resigned from the Government service to resume his practice as a member of the firm of Marr, Green & Co., Chicago.

OBITUARY

BRIG. GEN. JOHN M. WILSON, Corps of Engineers, U. S. A., died in Washington Feb. 1. General Wilson, one of the oldest retired members of the Corps of Engineers, was chief of engineers during the Spanish War. He was born in the City of Washington in 1837, and was graduated from West Point in 1860. He served through the Civil War with conspicuous gallantry, being brevetted a colonel in 1865. From the end of the war until 1897 he was on various stations in the engineer department, mostly in Washington. President Cleveland, at the beginning of his first term, placed the then Colonel Wilson in charge of public buildings and grounds in the District of Columbia, and in 1889 he was appointed superintendent of the Military Academy, which office he held for four years. When Mr. Cleveland became president again, in 1893, Colonel Wilson was again summoned to Washington to have charge of public buildings and grounds. He was appointed Chief of Engineers Feb. 1, 1897, and held the position for four years and three months. He retired from active service in May, 1901. General Wilson was a member of the American Society of Civil Engineers and past president of the Cleveland Engineering Society.

FRED J. SAUER, assistant engineer in the office of Metcalf & Eddy, consulting engineers, Boston, Mass., died Jan. 30. He had been connected with Metcalf & Eddy for about 1½ years. Mr. Sauer was the author of the article on "Raising Two Lines of 24-inch Water Mains Seven Feet," published in *Engineering News-Record* of Jan. 30, 1919, p. 254. He was both engineer and contractor for the work described, and personally made all the plans and supervised the work, coöperating with the officials of the Metropolitan Water-Works and the Boston Water-Works.

ROBERT S. VAN RENSSELAER, borough engineer of Punxsutawney, Penn., for ten years, died there Jan. 24. Mr. Van Rensselaer was born in Burlington, N. J., Oct. 27, 1847. He was graduated from Yale University, and was one of the two original engineers who surveyed the right-of-way for the present Cresson division of the Pennsylvania R.R., from Bellwood to Punxsutawney.

JOHN ATLEE, division engineer of the Philadelphia Terminal division, Pennsylvania R.R. Co., was killed in the tunnel under Chestnut St., Philadelphia, Jan. 9. Mr. Atlee was born at Wayne, Penn., Sept. 2, 1873. He was educated by private tutors and entered the service of the Pennsylvania R.R. as rodman on construction of the Georgetown Branch, Washington, D. C., in 1893. From 1894 to 1899 he was with the engineering department of the Fairmount Park Commission of Philadelphia. During 1899 and 1900 he was in Nicaragua with the Isthmian Canal Commission; later he was instrument man in charge of construction work on the Erie R.R. Mr. Atlee reentered the service of the Pennsylvania R.R. as rodman in the maintenance-of-way department, and was promoted through the grades of assistant supervisor and supervisor to that of division engineer of the Renova Divisioin at Erie, Penn., in 1917, and then in 1918, to that of division engineer of the Philadelphia Terminal division.

Government Will Dredge Delaware River Below Philadelphia

Dredging a 35-ft. channel in the Delaware River from Philadelphia to the sea is the reported purpose of the United States Engineers. It is estimated to cost about $3,000,000, and the work will be arranged into 10 districts, so as to be divided among several contractors.

The material to be encountered is soft mud, with some sand and gravel, and will be removed on scows. It will be deposited on shore or behind bulkheads by rehandling machines or other means.

The district engineer, 815 Witherspoon Building, Philadelphia, says that he is ready to give information to contractors or others interested in the project.

National Crushed Stone Association Will Hold Convention

The first annual convention of the National Crushed Stone Association will be held at the Iroquois Hotel, Buffalo, N. Y., Feb. 11-12, 1919. The association was formed in Chicago in February, 1918.

War Department Organizes Office for Selling Surplus Materials

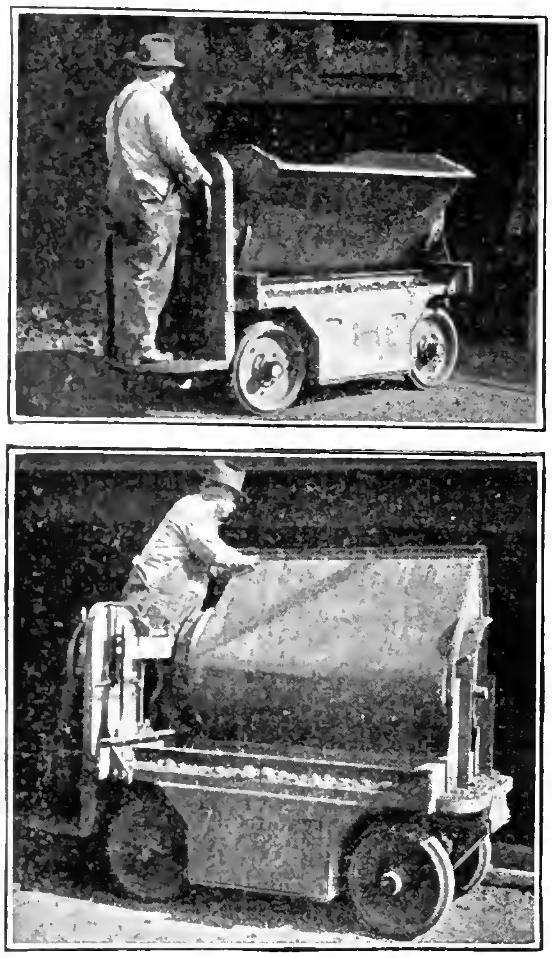
The office of the director of sales for the disposal of war materials no longer needed has been organized by the War Department. The work will be handled under the direction of C. W. Hare by a board of sales review composed of seven members. E. C. Morse is chairman of the board and each member is a division sales manager, except one, who is the legal member.

The class of supplies to be handled by each of the division heads includes machinery, construction equipment and material. Lieut. Col. A. LaMar has charge of machine tools, including all metal- and wood-working tools, railway equipment, steam shovels, locomotive cranes, gantry cranes, hand tools, forging equipment, iron and structural workers' power tools and machinery. Maj. W. W. Crunden has charge of building material, including lumber, millwork, fire protection, water-supply, fabricated steel, roofing, wall board, paints, refrigeration, hardware, brick cement, heating, machine equipment and electrical equipment. Col. Fred Glover has charge of trucks and motor equipment, including trucks, motors, motorcycles, side cars and all surplus supplies and repair parts pertaining thereto, animal- and hand-drawn vehicles.

Electric Truck Reduces Coal-Handling Costs

By the use of a storage-battery truck a Philadelphia manufacturer has reduced his coal-handling costs approximately 50 per cent. The truck is fitted with a V-dump body and hauls the coal from storage bins, where it is loaded by gravity, to the boiler house and store yard. The quick-loading facility, however, was a factor in this saving, since it was found that the truck could be loaded from the bin in 8 sec., the truck holding one ton of coal, whereas in loading the truck from the storage pile it was found that it took 5 min. to do this work by hand.

The coal-handling program commenced in the morning with a haul of 300 ft. from the storage bin to the boiler house. In two hours, however, sufficient coal was hauled to keep the boilers going all day, after which the trucks carried coal from the bins to a storage pile. It was found that in this program about 20 tons of coal were handled per hour. The haul from bins to storage piles was about 115 ft. each way. The loaded truck made the trip from bins to storage pile in 45 sec.,



HANDLING COAL WITH ELECTRIC TRUCK

the return trip having been made in 35 sec. The load was discharged in 10 sec. By this method the company was able to release railroad cars quickly and reduce demurrage charges. The receiving bins were emptied as fast as possible, so that unloading from the railroad cars could be started as soon as the cars were placed.

The truck is manufactured by the Lakewood Engineering Co., of Cleveland, Ohio.

England To Investigate South American Machinery Market

The Department of Overseas Trade of England and the British Engineers' Association will shortly dispatch a joint investigating committee to Brazil. The object of the investigation will be to ascertain the conditions and the prospects for the sale of British engineering products in Brazil. The cost of investigation will be defrayed in equal shares by the association and the Government, and the subjects to be covered include: Local importers, shipping methods, Brazilian law, statistics and England's chief competitors. The investigation will also include the following industries, so far as they are likely to provide openings for engineering plants and machinery: Shipping and shipbuilding; harbor and dock development; hydro-electrical possibilities, and the development of public utilities.

Business Notes

W. H. Kinsey, for the past 20 years selling water-works supplies, has been appointed New England representative, with offices at 201 Devonshire St., Boston, Mass., for the Warren Foundry & Machine Co., of New York, manufacturer of cast-iron pipe.

A. W. Greetham, manager of excavator sales of the Pawling & Harnischfeger Co., has resigned to accept a position with the T. L. Smith Co. as assistant sales manager. Mr. Greetham has been interested in the promotion of excavating and contractors' machinery for 10 years.

Bery G. Danley, formerly manager of the Haughson-Freenaughty Co., Spokane, Wash., has entered the general road-contracting business, with headquarters in Spokane.

The Blaw-Knox Co., Pittsburgh, Penn., announces that it will reopen its San Francisco office, at No. 528 Second St., in charge of Ensign Irving Burrows, recently released from the service of the Government.

Trade Publications

"Ladew Leather Belting" is the title of a 6 x 9-in., 108-p. catalogue issued by the Edw. R. Ladew Co., Inc., Glen Cove, N. Y. It illustrates and describes the manufacture of the company's leather belting, and also gives diagrams and other data regarding the use of belts.

Roadbuilding with Novaculite, a species of gravel, is the subject of a 23-p. pamphlet, $7\frac{1}{2}$ x $8\frac{1}{2}$ in., issued by the Egyptian Gravel Co., Railway Exchange Building, St. Louis, Mo.

The Economy Drawing Table and Manufacturing Co., of Adrian, Mich., has issued catalogue N A, 7 in. x 10 in., a 32-p. pamphlet illustrating and describing its drawing tables, sectional filing cases and other drafting-room equipment.

Price advances are indicated by **heavy type**; declines by *italics*.

Kansas City	Limestone	2.90 sq.yd.
Boston	5-in. granite	98.00 per M
St. Paul	Sandstone	1.75 sq.yd.

FLAGGING—

New York	Bronx	$0.20 sq.ft.
	Manhattan	.21 sq.ft.
	Queens, 5 ft. square	.20 sq.ft.
	5x20-in. cross-walk	.70 lin.ft.
Chicago	18 in. wide	.80 lin.ft.

WOOD BLOCK PAVING—

	Size of Block	Treatment	Per Sq.Yd.
New York	3½	16	$3.25
New York	4	16	3.50
Chicago	4	16	3.10
Chicago	3½	16	2.95
Chicago	City specifications		3.10
St. Louis	3½	16	2.45
St. Louis	4	16	2.60
St. Louis, Minneapolis spec.	3½	..	2.40
St. Louis, Minneapolis spec.	4	..	2.55
Kansas City	4	16	3.00
St. Paul	3½	Minneapolis specifications	2.50
Dallas	3½	18	3.17
Dallas	4	18	3.56

CURBING—Prices per linear foot are as follows:

New York	5 x 16	$0.45
	5 x 20	.55
Chicago	6 x 18	.95
St. Louis	5 x 16 square edge	.92
St. Louis	5 x 16 bull nose	.97
San Francisco	5 x 16	.65
	5 x 20	.80
Dallas	6 x 20	.45

An American Mayor

OLE HANSON of Seattle is a mayor to be proud of. Promptly and unanswerably he served notice last week that the legally elected representatives of the voters of Seattle would continue to run the city and that the first strike leader or other person who tried to usurp authority would be shot on the instant. Mayor Hanson's swift, manly action sets an example which may save other cities also from whimsical and tyrannous overnight attempts at minority government.

Irrigation Water Losses Increase with Temperature

THAT loss of water by seepage from irrigation canals may vary with temperature as much as 30% in a single season is the conclusion stated on p. 323 by an engineer who has been studying for many years the duty of water in irrigation. The studies on which this conclusion is based are part of a series carried on for an irrigation company during the past few years. The company deserves commendation for these investigations, as also do both it and the author of the paper for making them public.

Finish the Government Housing Developments

STOPPING a running machine dead is not good for the machine or its operator. It should be allowed to slow down. This seems to be the case with the Government housing program, as very cogently pointed out by Mr. Knowles on another page. Housing as an engineering problem is so new that the full benefit of the forced Governmental experiment is necessary to develop future possibilities. Half-finished projects will serve no useful purposes either to house workmen or to provide examples of practice. Let the Government complete all of the now necessary developments it has started, and leave the question of Government housing as a social panacea for future settlement.

Public Service Through United Engineering Action

TRUE public service was done by the engineers and engineering organizations that made the battle against the arbitrary action of New York City authorities in dismissing hundreds of engineers engaged in rapid-transit construction, a month ago. Now that the battle is won and the engineers have been reinstated, it is even clearer than before that the issue was of primary importance to the entire community and that those who championed the cause of the unjustly discharged men stood as the defenders of the public's interests. Though sympathy was engaged primarily by the immediate victims of official arbitrariness, the underlying spur to action was the certainty that necessary work would be paralyzed, to the community's great loss. By entering an energetic protest, the engineering profession took a step that is likely to be long remembered as a precedent. The success of this protest is an encouragement to further united action. No case could show more clearly than this one that in defending his own interests the engineer also serves the interest of the public. And if the professional interest can be upheld only through union, such union is not merely a privilege, an opportunity, but also a duty which every engineer owes to his fellow citizens.

Pass Some Kind of Water-Power Bill

NINETEEN days are left in which a Federal water-power bill can be enacted by the present Congress. If Mar. 4 goes by with the conference deadlock intact, years may pass before another Congress can bring a bill to the advanced stage the present Senate and House bills have now reached. Argument pro and con in the public prints can no longer avail much. Everything that is to be said has been said, except that it would be a crying shame to let petty differences now interfere to prevent the passage of some sort of act which will permit the necessary development of the water-powers of the United States.

An Engineer To Direct Construction

NEW lines of development of rapid-transit construction and planning in New York will come into prospect if the proposed appointment of Col. William Barclay Parsons to head the work is made a reality. There is so obvious a gain in handling a large construction enterprise through a competent and responsible directing head that many of the troubles which have attended the Public Service Commission's course would disappear. When five nontechnical men are set to carry out executive functions requiring knowledge of engineering and construction, difficulties are bound to develop. Of these, lack of coördination of thought is perhaps the most serious, and in New York transit matters very tangible evils have resulted herefrom. Governor Smith's offer to Colonel Parsons is reassuring evidence of progress in administrative methods—all the more so because it would separate the direction of construction work from rate regulation and other phases of state utility control.

Engineering Societies Show Greater Activity

THAT the organized activities of engineers are at last responding to the persistent exhortations of the past few years, that greater part should be taken in civic and social activities, is evidenced by the record found on the news pages of our last week's issue. Notice of a meeting of the New York members of the American Society of Civil Engineers, which developed an unusual discussion on the railroad situation and proposed principles of legislation; a suggestion by Michigan engineers for a state board of public works; a proposition by Indiana engineers for a joint license law with the architects, and insistence by Illinois engineers upon many kinds of state legislation—all are tangible demonstration that the profession is fast learning the art of progress through service. The time for talk and theorizing is past, the time for action has arrived. So many signs pointing toward right development are encouraging.

One Structure Where Operation Is Important

AS AN engineering performance, the Brooklyn Army Base is stupendous. Words and such illustrations as can be presented in these pages can suggest only faintly the hugeness of the operations that have been under way there for the past ten months. In its concentration of expenditure in comparatively small area it surpasses all of the many war jobs which have killed all hopes of record-breaking structures for many years to come. Everyone connected with the design and the construction helped mightily toward the winning of the war, though the base itself never got into operation. But in contrast to many war structures—or in fact, to most of the structures that civil engineers build—the most important interest in the base will be its operation. Together with the companion terminal at Boston, the Brooklyn project is expected to have a peace-time use as a freight-handling unit. It is, however, far larger and more elaborate than any similar terminal ever built, and this very elaboration complicates the design. The only excuse for a huge unit port terminal is the expected saving due to an orderly and rapid movement of freight plus the flexibility in operation and storage brought about by the immense warehouse area. On the economy of such projects as this, then, depend in great measure the future development in port designs and—not so far removed—the future of our merchant marine.

Motor-Driven Tractors Prepare Land for Irrigation

MOTOR-DRIVEN machinery was used in preparing a large tract of California land for irrigation, as described on p. 337. This practice will increase, since it is now seen that neither public nor private agencies do their part by merely selling so much rough land and so much water to the settler, but that they should level and perhaps otherwise prepare the land for the first crop and deliver water to the farmers' ditches. The apparent but not the real first cost of the farms will be increased by this practice. In the long run, both capital and operating charges will be reduced, and many a farmer saved from disappointment and disaster if his land is ready for cultivation when he takes possession of it. Besides the economy of large-scale operations under engineering direction, and the possibility of getting crops from all the land the first year, the farmer knows at the start just what the ready-to-use land will cost him, instead of facing the many risks due to uncertainties.

Motor-Truck Routes as Substitutes for Railway Branch Lines

FOR many years some British railways have preferred to run vehicles over highways into regions where comparatively little business originates, rather than to construct and operate branch railways. It has been known for some time that the engineering section of the United States Railroad Administration has been considering this subject. At the Jan. 16 meeting of the New York Railroad Club Charles A. Morse, in charge of engineering and maintenance in the Railroad Administration's organization, indicated his belief that under some conditions motor trucking would answer all the purposes of a branch line and save the railroad company the almost invariable loss which the operation of a branch entails. This is not a new thought from a railroad official. The late W. W. Finley was an ardent advocate of the improvement of roads leading out from railroad stations, and some of the most able arguments ever made for such betterments were presented by him with this principle of economic transportation as the basic reason for such public work.

It is pointed out by Mr. Morse that a branch railroad can often be built at a lower cost than a highway suitable for motor traffic, but this branch can only be used by rolling stock. The highway must be built, anyway. The economic problem is to determine whether it is wise to put enough money into the highway to make it fit for motor trucking, or whether it is better to leave the road fit only for light vehicular travel and put money into a branch railroad for the heavy freighting. Mr. Morse acknowledges that there may be branches which should be abandoned and their roadbeds turned into highways. He points out that long hauls by motor trucks may save transfer charges and other expenses which make branch lines unprofitable to the company and the shipper alike. In short, he takes the position that the subject to study is transportation as a whole, and not the relative merits of trucking and railway haulage as unrelated, conflicting rivals.

It is refreshing to have these comments from an eminent railway engineer. It is gratifying to have another dispassionate appeal for a comprehensive study of the economics of transportation from the viewpoint of the shipper and taxpayer and security holder. The engineering features of both railroad and highway construction are very simple, even elementary, compared with the economic problems which are presented by any real investigation of the choice of mode of transportation to be improved. These economic problems are little appreciated and still less studied. Moreover, in the present state of knowledge, essential data are to a large extent lacking in regard to highways. Nobody has been commercially interested in intensive and intelligent

studies of the transportation facilities which will best serve the welfare of the great mass of the people. But until such studies are made, and we really know as much about transportation as a whole as we now know about that limited part of transportation between the receiving and delivery doors of railroad freight houses, we are doing a good deal of guessing about what is the best thing to do. Some of our guesses will be incorrect and cause a waste of money.

Keeping Up the Shipbuilding Spirit of Shipyard Workers

WHEN we read of shipyard strikes here and there in the country, strikes of which that at Seattle is only a pronounced example, we link the news with other items on labor unrest, and think no more of causes. The phenomena of readjustment are hard facts. One man may call them inevitable, and another may charge them to unwise leadership, but they are with us, whether in textile mill or in copper mine or in shipyard.

But conditions in the shipyards are fundamentally different from those in other productive industries. Shipbuilding is not glutted with stocks like the copper field, or confronted by an uncertain market like the textile field. Its hours and wages are controlled by the Macy board. There are not the same causes for dispute as at Lawrence and Lowell. If conditions, then, are in every respect favorable to stability, to efficient production, the Emergency Fleet Corporation has at its command an engine of production that should function without friction. Yet there are strikes and disputes.

Four months ago we needed ships urgently. We need them just as urgently today. Four months ago every shipbuilding agency was driving forward at full speed; but today, though the drive is still on, it has not the same intensity of spirit.

Serious concern has been aroused in some shipbuilding districts by orders received from the Emergency Fleet Corporation to cancel plans for starting work on ships that would be completed late in the year. Among managers as well as among workmen, apprehension grew that shipbuilding would soon be brought to a stop. If the results are a safe criterion, these apprehensions played a part in stimulating unrest, in reducing efficiency, and in building up a strike sentiment.

The unfortunate part of the matter is that no curtailment of the shipbuilding program is involved either in this order or in prior orders issued by the corporation since October, and that nevertheless rumors of curtailment have been allowed to exert their harmful, disturbing influence.

Revision of the shipbuilding program with respect to types and sizes of vessels is now in progress. This important work will be of maximum value if its results can be applied as soon as possible, and are least hampered by the presence of keels on the ways and material in process. While this very good reason for the Fleet Corporation's order existed, yet an announcement in arbitrary form was allowed to disturb the working spirit of the yards. Together with earlier orders and announcements of the Shipping Board and the Fleet Corporation, it added measurably to the causes of industrial unrest.

An uncomfortable addition to the psychology of the moment has thus been made quite unnecessarily. Most urgent reasons exist, in the need for prompt steadying and resumption, for the exercise of tactful care in announcements and orders relating to labor matters and discontinuances. In the past the Fleet Corporation has often had to act summarily and sometimes in arbitrary manner. Now, however, the war period is over, and whatever causes may have justified arbitrary action and secrecy on the part of the corporation in that period have disappeared. The present times call for changed methods.

A Commission to Study the Colorado and Save Imperial Valley

JUST before the Colorado was turned back into its channel in 1906 a retreating waterfall marked the head of a new low-level channel which was moving up stream at the rate of one-fourth mile a day. With the repair of the break, the destructive waterfall was dried up, but there was left the long, deep channel through which the water had cut a way to Salton Sea. Should flood waters once again pour into that channel until its head cuts back across the present river bed, the fertile lands of the valley would become the bed of a great inland sea. There would be no hope of turning the river out of a channel cut below sea level. Last year's flood saw water lapping at the crest of Volcano Lake levee with nothing but low land beyond, and that sloping toward the dangerous channel cut in 1906. It is well known that the bed of the Colorado silts up rapidly, and no one can say how soon the flood menace may again become a reality in this as well as in other ways.

Too much emphasis, therefore, cannot be placed on the urgent and immediate need of protective measures. The half-million acres of irrigated lands in Imperial Valley alone produce annually crops valued at $25,000,000. It is absurd to jeopardize such valuable lands when permanent safeguards can be certainly and economically provided. Because of the present-day importance of productivity, such as that for which Imperial Valley is noted, it is more than ever necessary that the needed protection be provided speedily. Governor Cantu, of Lower California, has indicated his willingness to consider plans for improving the present situation, and the recent Imperial Irrigation District, election, on Jan. 21, although of no legal binding effect, was almost three to one in favor of the proposed contract with the Secretary of the Interior for an All-American canal, and nearly six to one for control by the United States Reclamation Service and for reservoir regulation of the Colorado.

In these conditions, the present is a most opportune time to take up in earnest the control measures so long deferred. Surely, there is common ground on which the various interests involved can get together and forget the petty quarrels that have made enemies of adjacent districts. Uncontrolled, the river is a constant menace to all, but with proper regulation it could be made a safe source for additional water which would

make possible a greater irrigated area for all the districts involved.

By way of constructive suggestion, the following is proposed as a means of securing the measures necessary: Let there be formed a Colorado River Commission consisting of three members, one representing the Reclamation Service and one representing the United States Army Engineers, and let these two select a third to represent independent irrigation interests. Such a commission, taking into consideration the rights of all irrigable areas involved with respect to the maximum use of all the water that can economically be made available, should be able to agree upon the necessary protective measures, more particularly the number and location of storage reservoirs on the head waters of the Colorado. It should also estimate their approximate cost and apportion the shares of such costs. This last might be done in the expectation that half the money would be apportioned by Congress from Federal funds, contingent upon the raising of the remainder from state and local sources. Precedent for the general features of this plan is found in the somewhat similar plan applied in the Mississippi levee districts and the Sacramento River flood-control districts. The findings of such a commission should receive the united support of water users along the Lower Colorado, if there is a reasonable degree of willingness to get together on common ground. Moreover, the report of such a commission would constitute the logical starting point for an international commission to draw up some form of agreement to which both the United States and Mexico would subscribe.

The foregoing suggestion is based wholly on economic considerations. For the good of the country at large, and particularly for those interests concerned with the control of the Colorado River, some such plan should be adopted at the earliest possible moment.

Federal Aid and Co-operation in Rural Public Health Work

THERE has been introduced in Congress by Mr. Lever a bill to provide means for the prevention, control and mitigation of the diseases of our people living in the country and in towns of not more than 5000 population. The United States Public Health Service is designated as the agency of the Federal Government in this work, and the states are to be represented by their health departments or officers. The bill carries an appropriation of $480,000 annually to be allotted $10,000 to each State, besides an appropriation of $250,000 for the current fiscal year, $500,000 for 1920, $750,000 for 1921, and $1,000,000 annually after 1921. After deducting administration expenses, not exceeding $50,000 annually, from the appropriations, the annual Federal contributions are to be divided among the states in proportion to their areas and to their rural populations, one-half on each basis. In order that any state shall receive any of this money, it must first give official assent to the law and agree to furnish an equal sum from its own funds, after the current fiscal year. The regulations governing the cooperative work are to be drawn by the Secretary of the Treasury, just as the Secretary of Agriculture draws the regulations governing the laws of this type now in force.

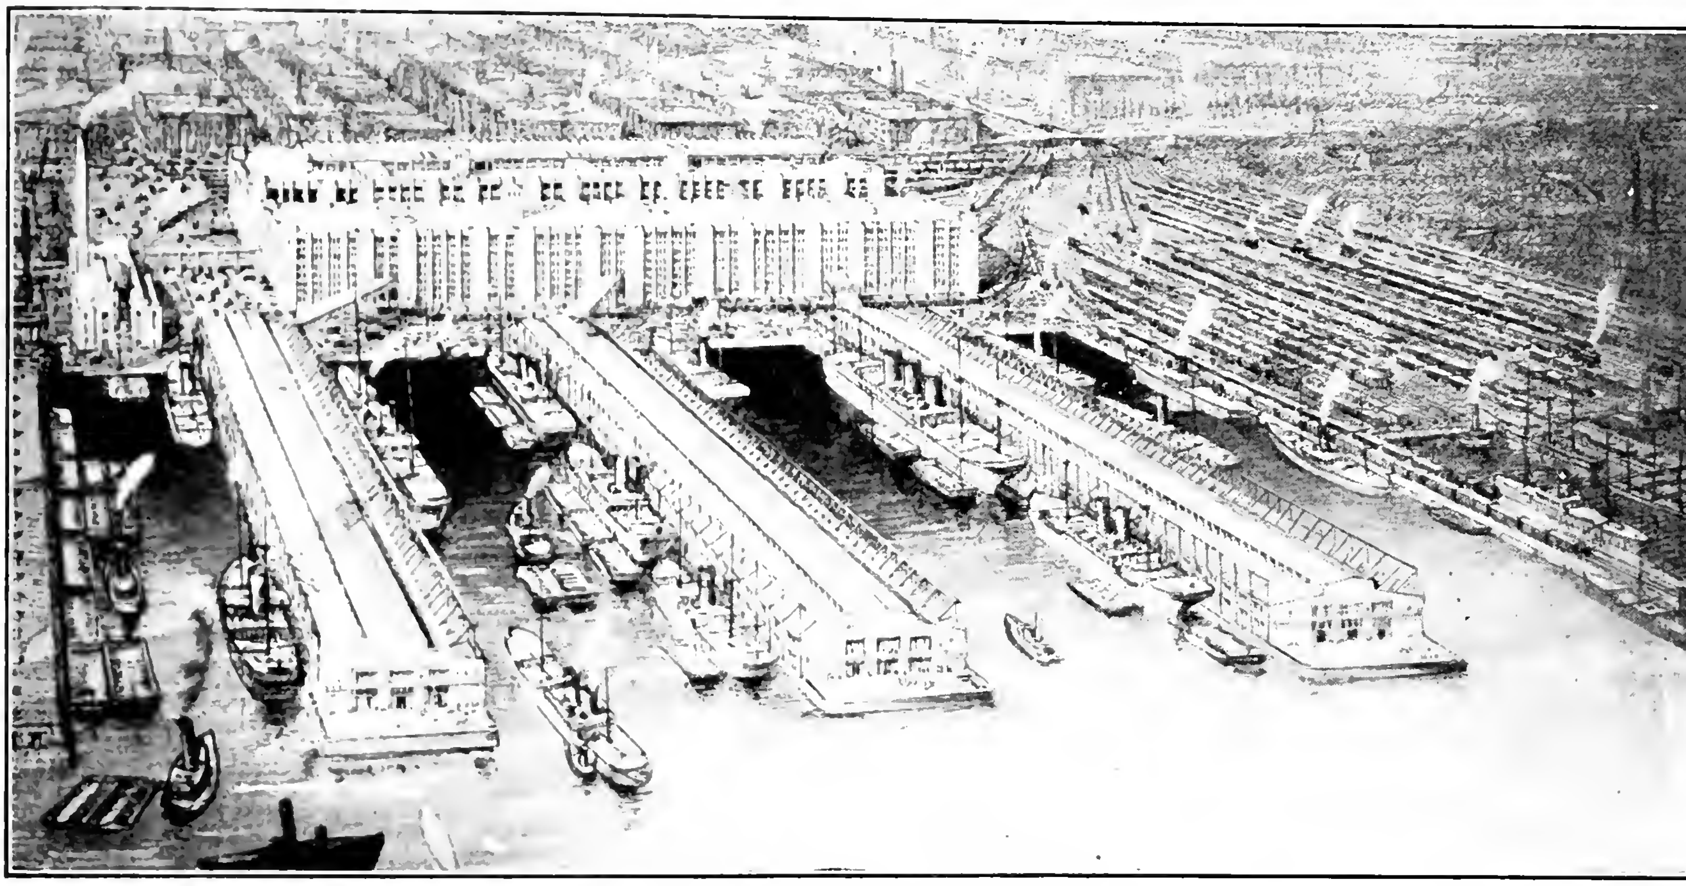
The importance of this act is capable of numerical demonstration, and does not rest on generalities. Its objects will be attained when the people in the country and in the little towns know what they can do to protect themselves against disease and apply this knowledge, thereby eliminating the diseases which are now common but which should be matters of medical history. Our large cities have gone a long way toward that desirable end. The cities in the states maintaining public health registration service had their death rates decreased an average of 21.2% in the period 1900-1912, while the death rate in the rural sections decreased only 8.6 per cent. The last typhoid-fever census figures were taken in 1900 and showed that even that disease, peculiarly likely to occur in cities, was actually more prevalent in the country, outside New England. The Public Health Service estimates that as a result of unsanitary conditions in the country and in the small towns there are 350,000 cases of typhoid annually in such sections, with about 30,000 deaths. There are about 9,000,000 cases of malaria and 3000 deaths. The service estimates that the economic loss from these two causes in the country is about $900,000,000 annually. Then there is the hook-worm disease, also due absolutely to unsanitary conditions. There are about 2,000,000 cases of this, and some of them are fatal. Economists have not yet reached a satisfactory estimate of the financial burden of this disease, because persons afflicted with it have their working value reduced from one-fourth to one-half, so that any estimate of the financial burden due to the disease must be far less accurate than that for typhoid or malaria. The detail figures have recently been made public, in part, in Bulletin 94 of the Public Health Service, so it is unnecessary to go into them here.

The bill is specially interesting to the sanitary engineer in that, if it is passed, it will enable him to have the support and coöperation of a fairly efficient rural health organization, wherever his work may be done. The Public Health Service is coöperating in some places with the county agents working under the Lever act of 1914, because of the inadequate provisions made in such localities for local health work. The typhoid and malaria brought to the cities annually by persons who have been spending their vacations in the country give the urban resident a very strong reason for backing this proposed law. The sanitary engineer who is trying to force the innumerable little towns of the country to clean up and stay clean will find in this proposed legislation the help he has heretofore sought in vain. There is nothing spectacular about these small local skirmishes with filthy and slovenly conditions; they have none of the interest of the engineering problems of the larger cities. But they are of great collective importance, and call in many cases for just as much good judgment and engineering ability as larger operations, so that the Lever rural health bill, as it is called, is really a measure of unusual significance to a very large group of engineers who are rendering the same valuable class of service that is performed by the country doctors.

Brooklyn Army Base Is Largest Port Terminal

Huge Freight-Handling Unit Designed for Overseas Service Has 138 Acres of Pier and Warehouse Floor and Track Space for 1300 Cars—Designed as a Whole for Rapid and Economic Operation

THREE deep-water piers, each larger than any other pier in New York harbor, a small lighterage pier, two reinforced-concrete warehouses with 91 acres of storage floor, and railway yards accommodating 1300 cars, make up the huge Army base which was rapidly approaching completion in Brooklyn, N. Y., when the armistice was signed. Begun in May, 1918, the whole terminal would have been well toward completion by the end of the year had not the return of the eight-hour day, following the armistice, precipitated strikes which cut down the output. As it is, the buildings and one pier are now nearly ready for service. About $17,000,000 had been paid out, in the nine months up to Feb. 10, which puts the operation near the head of the concentrated building constructions incident to the war.



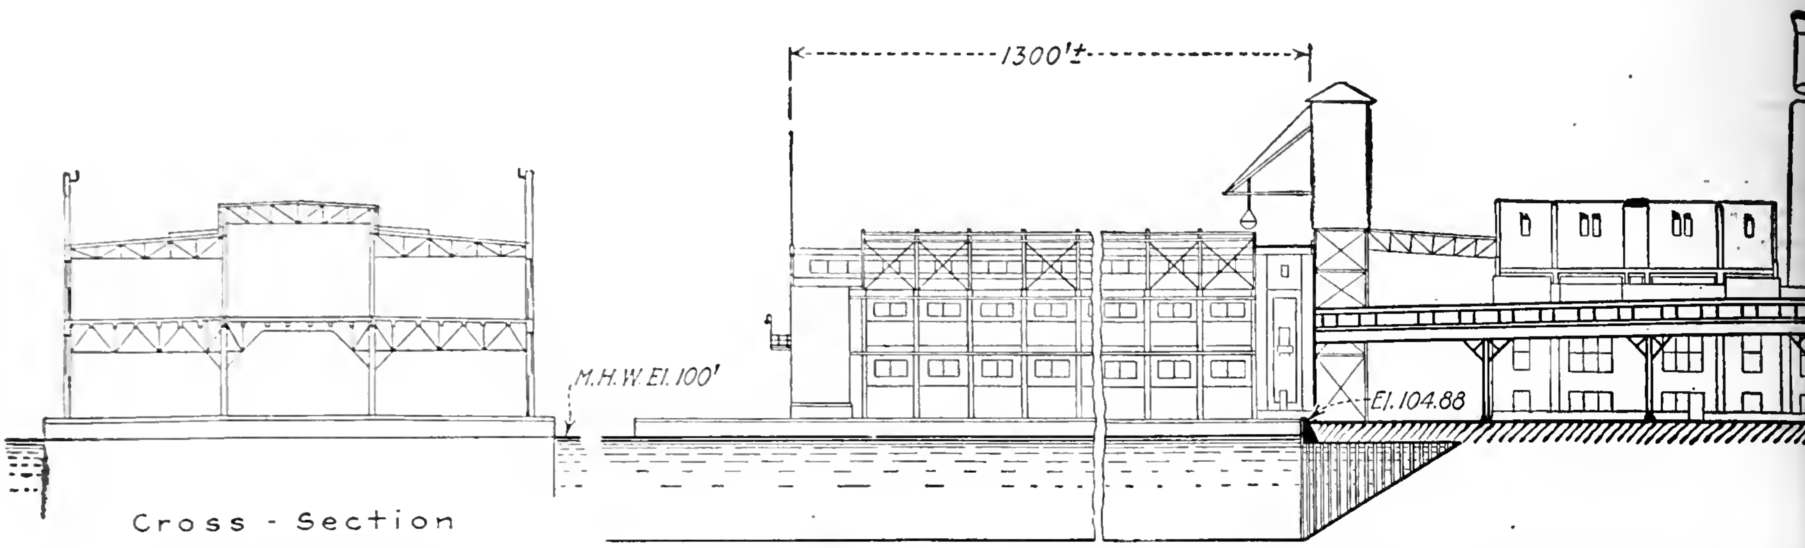
PERSPECTIVE OF FINISHED BROOKLYN ARMY BASE FROM THE WATERSIDE LOOKING SOUTH

Individually, any one of the units which make up the Brooklyn base is a large and important engineering structure worthy of detailed description. Collectively, the whole project is a remarkable example of a modern freight-handling port terminal, a necessary shipping element hitherto rare in this country. The attention of this article, therefore, will be mainly directed to the composite design of the base rather than to those structural details which in so enormous an undertaking would require space far beyond that available here.

The Brooklyn Army base is the largest and in many ways the most nearly complete of the six port terminals built in 1918 to handle the supplies to the American Army in France. Soon after the United States entered the war a committee of the Council of National Defense, in coöperation with the War Department, made a thorough study of the storage and traffic necessities, as a result of which they recommended the establishment of a series of interior and ocean terminals which would insure a steady flow of the needed materials to France. For one reason or another, however, the port terminals themselves did not get under way until nearly a year after the war was started. Few of them were in operation at the time of the signing of the armistice. Their design was predicated on a war use, which meant primarily that the material through them would flow mainly from land to the ship. Where any question of alternative design arose, the war use naturally controlled, but in the permanent terminals of the Boston and Brooklyn type the possible future peace-time use was always kept in mind.

The terminal is located on the east shore of New York Bay, immediately alongside of the harbor terminal of the Long Island Railroad, with its car-storage tracks and car-float bridges permitting transfer to and from any part of New York harbor. Here an area extending 1560 ft. along the waterfront and 1305 ft. back of the main bulkhead line was taken over by the Government. This extends from Second Ave. to the bay; the total land and water area of 100 acres (including the cross streets and First Ave.) is all inclosed in the Government reservation.

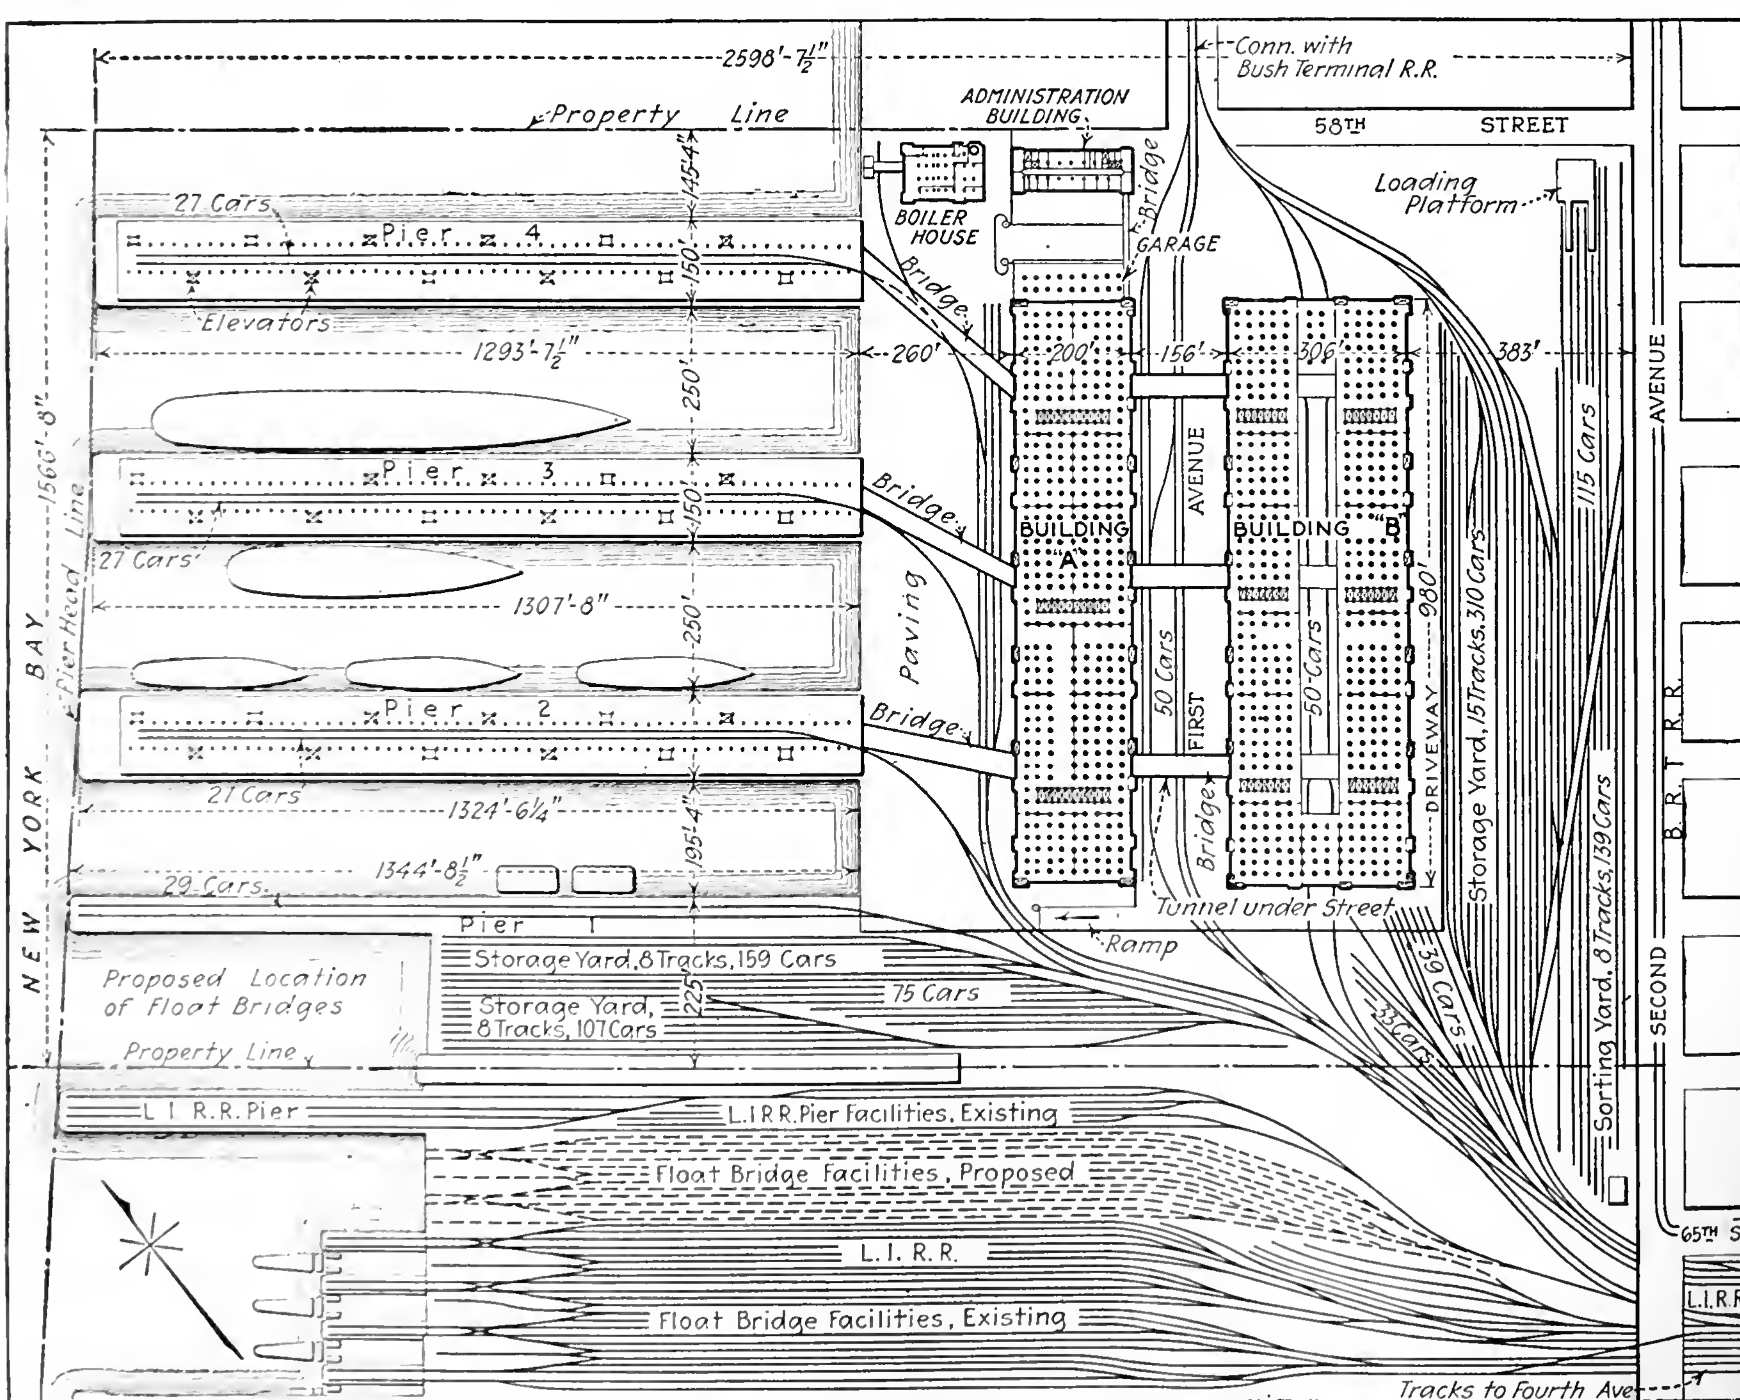
As shown in the accompanying map and plan of the base, the terminal consists essentially of two large reinforced-concrete warehouses connected by tunnels and bridges, approached by railroad tracks and paved streets, and further connected by a paved area and bridges to three double-deck piers, each 150 ft. wide



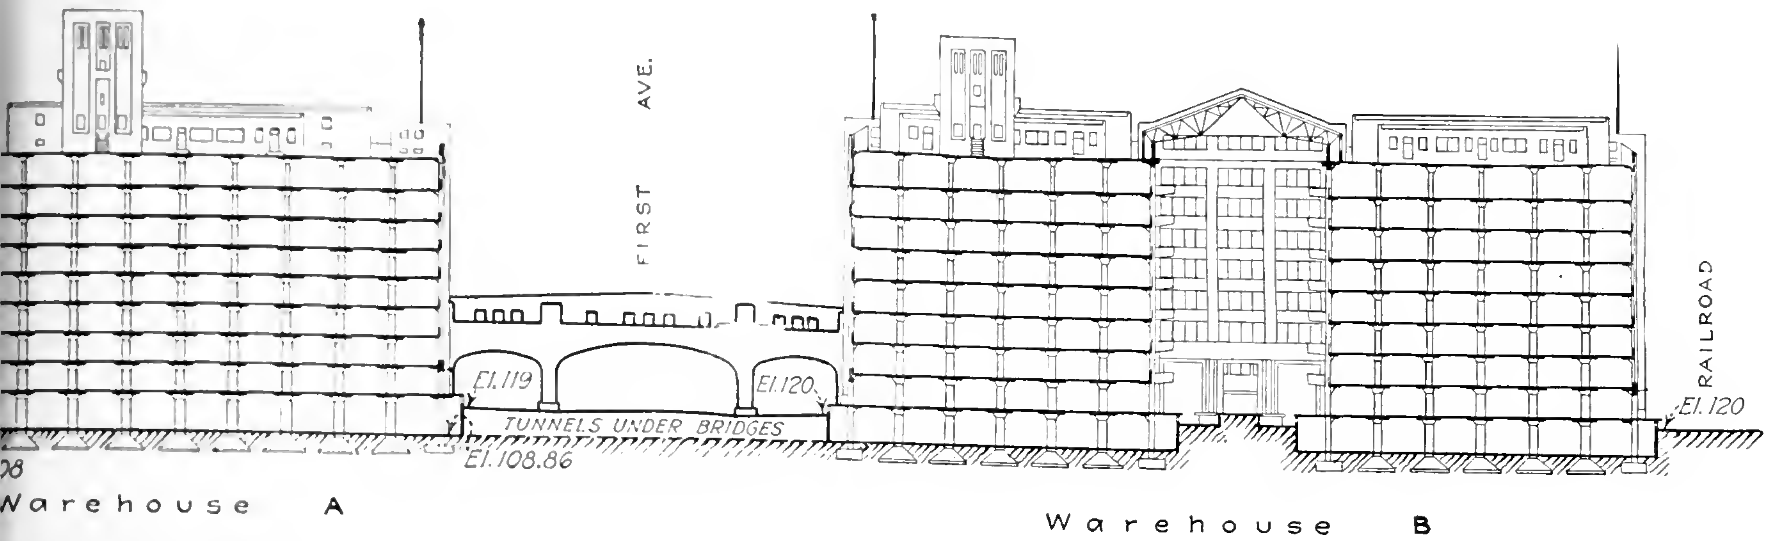
CROSS-SECTION THROUGH THE BROOKLYN ARMY BASE SHOWING, FROM THE LEFT, ONE OF THE 1300-FOOT PIERS WAREHOUSE B, AND WAREHOUSE

and varying in length from 1294 to 1325 ft., the variation being due to the fact that the pierhead line is not parallel to the bulkhead line. There is in addition a 60-ft. lighterage pier 1345 ft. long on one side and about 600 ft. on the other, and the necessary administration building and boiler house. Tracks paralleling the warehouses and the slips at the south end of the site provide storage for cars. South of the site is the large storage yard of the Long Island R.R., connection to which is made at the southeasterly end of the site. Track connections at the north end of the site lead to the Bush Terminal railroad. The slips, with a maximum width of 250 ft., are dredged to a depth of 35 feet.

The warehouses are of reinforced-concrete construction throughout and of similar structural design. Building A, the one nearest the wharves, is 200 ft. wide and 980 ft. long, and eight stories and deck story



PLAN OF THE NEW ARMY BASE ON NEW YORK HARBOR AT BROOKLYN



HE BRIDGE CONNECTING THE PIERS TO WAREHOUSE A, FIRST AVENUE, AND THE BRIDGE CROSSING TO WITH THE RAILROAD YARD

high. It has a floor area of 41 acres. Building B is 306 ft. wide, 980 ft. long, and has eight stories and basement. Its floor area of 50 acres makes it the largest concrete building. It has an interior court 66 ft. wide, covered over with a steel and glass skylight, and provided with concrete track girders on which run girder cranes controlling the freight on the cars which run through the court. Extending out from the windows of the court at each floor are concrete balconies onto which material is loaded for transfer to or from storage on the floor. These balconies are staggered in plan so as not to interfere with each other. The two buildings are connected by three lines of bridges at the third floor and tunnels at the basement of warehouse B to the dock floor of warehouse A, all being in direct line with bridges leading to the piers.

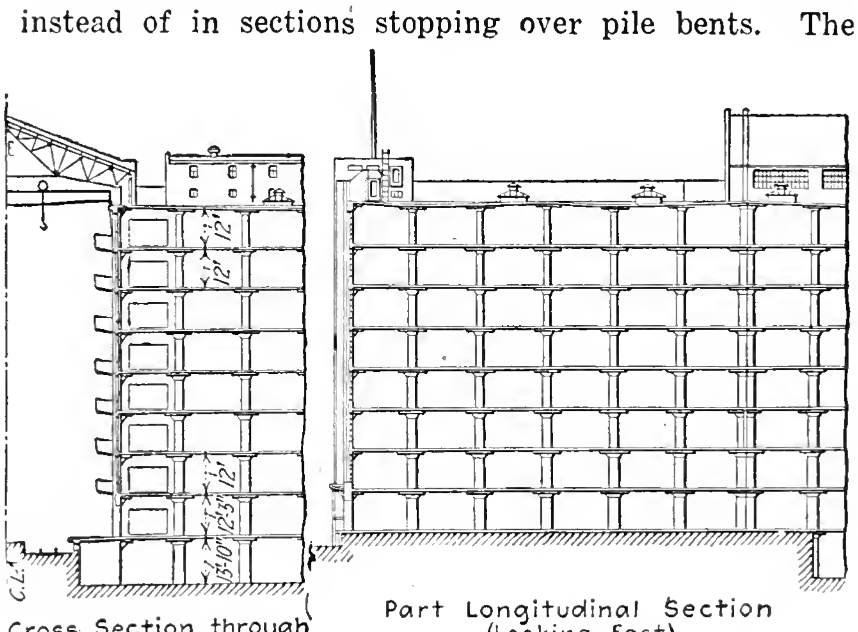
Both buildings are of the two-way flat-slab type, with round, spirally reinforced columns. The curtain walls are of concrete throughout. Intermediate partition walls, located as shown on the typical floor plan, are also of concrete. The design of these buildings is in accordance with the local city regulations and the provisions of the National Board of Fire Underwriters. The first, second and third floors are designed for a live load of 300 lb. per square foot and the upper floors for 250 pounds.

Building A is supported on reinforced-concrete spread footings, using a total safe load of 3 tons per square foot, with the exception of a small part of the building where a continuous mat footing was used on account of poor soil. Building B has the same type of foundations except at the north end, where Raymond concrete piles were used to eliminate the excessive excavation that would have been required for spread footings. Each of the buildings is divided into four separate parts by three expansion joints, their location being determined by storage space requirements and elevator groupings, but in general being about 300 ft. apart.

Outside stairways are provided in pylons, according to fire-protection standards, and the windows are all wire glass, those having exposure being of the Underwriters' type. Architecturally, the buildings are fairly simple, but the general effect is remarkably fine. The tremendous emphasis of so great a pile as either of the warehouses cannot be escaped in any part of the site. This effect can only be partly implied by the photographs of them which are reproduced herewith.

The three main piers are identical in design and size, except for the slight variation in length. They are 150 ft. wide and from 1294 to 1325 ft. in length, and carry over practically all of their area a double-deck shed, with first-floor tracks and roadway connecting with the main level of the yard, and the second floor connecting by simple plate-girder steel bridges to the third floor of building A, where they enter in front of the elevator banks. Slips 250 ft. wide are dredged to 35 ft. now, and in one case to 38 ft., but the substructure will permit the 40-ft. New York harbor standard.

The substructure follows the design of similar piers in the New York district; that is, untreated wood piles carrying, above the water line, timber caps and a reinforced-concrete slab deck, with pile clusters capped at mid-tide for the pedestals under the columns. A departure from local practice was the design and construction of the concrete deck as a continuous slab instead of in sections stopping over pile bents. The



DETAILS OF PARTS OF WAREHOUSE B

early practice had been adopted because of fear of unequal settlement of the bents and consequent severance of continuity, but the present designers were willing to assume this continuity, with a consequent saving in steel.

Structural design of the pier superstructure was made at a time when there was the greatest demand

for saving in steel, particularly in plates, which were needed for ships. The resulting design, therefore, does not follow current practice, nor is it advanced by its authors as the best possible under normal conditions. Its main difference is in the use of longitudinal concrete stringers and wood roof purlins, as a part of a structural steel frame, the unusual arrangement of the middle-bay cross frames, and the use of a side-bay truss instead of a girder. All of these details saved steel, especially plate steel, the claim being that in each pier the saving in plates over normal design was enough to build one ship.

Each shed is in three continuous bays for the full length of the pier. The second floor, a concrete slab, is supported in the outer bays in trusses with longitudinal girders of reinforced concrete supported on brackets on the steelwork and in the middle bay on a cantilevered frame, of which the supporting members are trusses and the suspended members a Bethlehem 26-in. girder 20 ft. 8 in. long. The roof, with a center bay monitor, is a light steel truss carrying wood purlins and sheathing with tar roofing. Outside columns rise above the roof and carry the longitudinal beams from which freight-handling hoists are hung, according to local practice. All openings in both decks have metal doors which slide back under the ceiling.

Loadings of 500 lb. per square foot on the first deck and 300 lb. on the second were provided for.

Between the piers extends a bulkhead which consists of a concrete wall resting on a pile and timber platform, and retaining about 10 ft. of fill some 25 ft. out from a row of sheet piling.

Full provision has been made for the lighting, heating, drainage and water-supply of the entire base, an engineering operation of considerable magnitude but of no particular complication. Warehouses and piers are all provided with sprinklers and high-pressure service lines, as well as connections to the pumps in the boiler house. Light and power are purchased from the local service company, but all heating service comes from the central boiler house. The administration building is a reinforced-concrete structure of the office type connected by a bridge to warehouse A.

The pavements in the base are of three types, depending on traffic conditions and considerations of laying. Granite blocks are laid on First Ave. and on the streets south and east of the warehouses and on the ramps between First Ave. and the bulkhead. Bitulithic pavement is to be laid in the area between building A and the bulkhead, and asphalt block will be used on the first deck of the piers, on the bridges to the warehouse A, and over First Ave., and on the loading platforms and main traffic aisles in the warehouses. Concrete floors in buildings and on the second floor of the piers have a 1-in. granolithic surface. Quantities are 47,000 sq.yd. of granite block, 44,000 sq.yd. of bitulithic, and 104,000 sq.yd. of asphalt block.

Granite blocks are laid under standard New York specifications, on a 2-in. sand bed over a concrete base. Each block is about $5\frac{1}{4}$ in. deep, except in track areas, where it is 4 in. deep and is laid on a 1-in. sand cushion. As the tracks are laid with a T-rail instead of the usual girder rail, the blocks adjoining the rail have a flanged groove cut $2\frac{1}{2}$ in. deep. Expansion joints are placed transversely over the pavement every 50 ft. and over the edges of the tunnels between buildings. The base in all cases is a 1:3:5 gravel concrete 6 in. thick without expansion joints. The blocks are grouted with a 1:1 grout.

LOOKING EAST FROM LONG ISLAND TERMINAL TOWARD BUILDINGS NEARING COMPLETION

Bitulithic is the standard pavement made by the Warren Bros. Co., and has an 8-in. concrete base. Asphalt-block pavement on the piers is made up of 5 x 12 x 2-in. block made by the Hastings Pavement Co. This pavement is laid on a base prepared of moist 1:3 grout $\frac{3}{8}$ in. thick and struck to a plane surface.

As an indication of the tremendous size of the whole project, a few of the total figures are given in the accompanying table. (See page 322.)

As stated at the beginning of this article, the fundamental design of the terminal was made to insure the even flow of freight to the outgoing ships. To this end the warehouses are in effect reservoirs for the storage of such freight as cannot be transferred immediately to the ship. A direct and readily usable connection between the warehouses and the piers had therefore to be provided, at the same time permitting

Detail of Hoisting Stirrup

Detail of Conn. of Cargo Beam to Column

Half Section of Shed and Section and Plan of Substructure at Column Footings

Half Section and Plan of Substructure between Column Footings

an alternative loading or unloading of freight direct to the piers or its temporary storage in the warehouses whence it is to be rehandled. Two definite traffic levels are provided, the lower being the level of the first deck of the main piers, the open area between building A and the water, the lowest or dock story of building A and the tunnel connecting buildings A and B and the basement of building B. At an elevation two stories above it is the second deck of the pier, the bridges from the piers to building A, the third stories of the warehouses, and the bridges between them. At an intermediate level is First Ave. between buildings A and B, which is connected by ramps to the bulkhead areas.

Entering freight, therefore, will come either via railroad or on truck. Railroad cars can be brought either over the car floats to the Long Island yard, from the Bush Terminal at the north, or from the yards of the Long Island R.R. at the east, which yards can

Longitudinal Section through First Deck

DETAILS OF ONE OF THE LARGE DOUBLE-DECK PIERS, ARMY SUPPLY BASE, BROOKLYN

be reached via any of the car floats to Long Island or the Hell Gate bridge from the mainland some miles north. Railroad cars stored in the various storage yards can be switched onto the tracks adjoining the east side of building B, in the court of building B, along the center of First Ave., along the east front of building A, or directly onto the first deck of the piers. Trucks will all enter the site from the main entrance at the northwest corner. They can be drawn up along all sides of building B, or on the east side of building A, or they can run down the ramps to the pier level and either approach the west side of building A at its dock floor level there or be run directly onto the first deck level of the piers themselves.

The loading and unloading platforms of the terminal will accommodate a total of 129 cars, and on the bulkhead space west of building A, in addition to the loading and switching tracks, two storage tracks are

LOOKING NORTH TOWARD BUILDING B OVER RAILROAD YARD, BROOKLYN ARMY BASE

provided, accommodating 36 cars in storage, which can be unloaded by derricks onto the bulkhead space if necessary. Each pier is provided with two tracks, 1200 ft. long; allowing 50% empty for traffic requirements, these will accommodate 28 cars each, or a total of 84 cars on the three piers. The completed yards will include about 17 miles of track and 172 switches, and will provide storage for a total of 1300 cars.

The standards followed in the track work are those of the United States Army and the Director General of Military Railways. Eighty-pound steel rail of the A. R. A. section is laid on all curves and through turnouts and on drill tracks and leads subject to much traffic. The balance of the yard will be laid with 67½-lb. Russian rail, which was rolled for the Russian railways and which, after the Russian revolution, was diverted for use in this country. No tie-plates are used, but all curves are double spiked. The maximum curve is 300-ft. radius except one instance at the First Ave. connection, where a curve 274-ft. radius is used. Within paved areas granite block is to be laid between and outside of the rails, and ground levers are to be used at the switches. The ballast is cinders 6 in. deep under the bottom of the tie.

The truck-unloading platforms of the warehouses will accommodate 228 motor trucks, and in addition, freight may be delivered direct to the piers by truck. Furthermore, of course, lighters may be unloaded along the 60-ft. pier.

In the expected operation of the terminal, the two general traffic levels will be the main arteries of traffic

Item	Buildings	Piers	Misc.	Total	Unit
Land area of reservation				57	Acres
Water area, including that occupied by piers				43	Acres
Area occupied by building and piers	12	15		27	Acres
Land excavation				704,000	Cu.yd
Dredging				1,700,000	Cu.yd
Total floor area	4,699,000	1,220,000	40,000	5,959,000	Cu.yd.

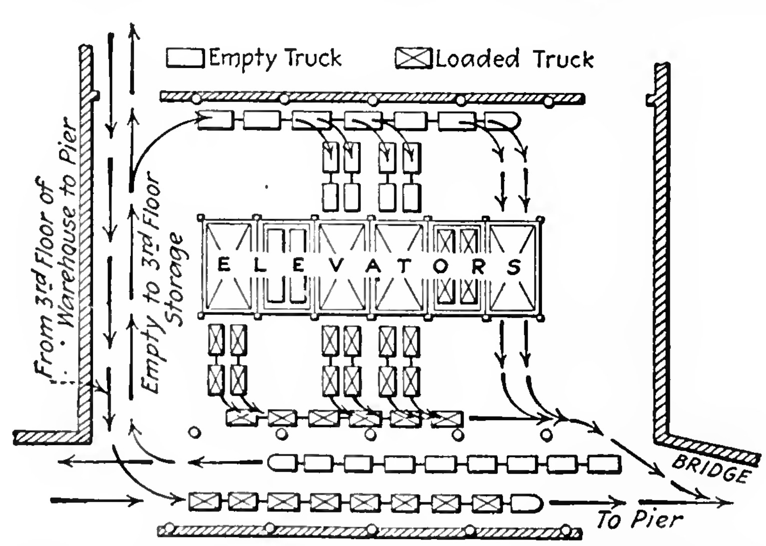
R.R. track, storage capacity (including railroad track on piers)				20	Miles
Railroad track, storage capacity				1,300	Cars

and the other floors will be used entirely for storage. All material will be moved from truck or railroad platform to elevators by industrial trucks and trailers, from the elevators to the required storage floor, there to be placed by tractors and trailers. In rehandling, all material will be taken from its storage location by elevators to one of the two traffic levels, and thence carried to the pier for unloading. Special provision in the court of building B is made for the handling of packages from the freight cars or trucks to the staggered balconies shown on the drawing. Onto these balconies may be run the small trailers, and the materials dropped onto them from the traveling cranes. No provision for outside handling of freight to different floors is made on building A, except that the tracks west of the building are so close as to permit unloading of cars on them by whip hoists which can be put on the roof of building A.

A total of 90 freight elevators is to be provided in the various buildings and piers. Building A has three



DETAILS OF OPERATION OF TRACTOR TRAILERS AT ELEVATOR IN WAREHOUSE

groups of ten each and building B six groups of seven each. There are, besides, one passenger elevator in building A and two in B, with provision for four in each.

As shown in the drawing, the elevators are arranged in three groups, at the ends and middle of each of the buildings. These elevators are of 10,000-lb. capacity traveling 150 ft. per minute, and have 9 x 17-ft. clear floor space. They are so designed as to accommodate four trailer trucks at one time. They are to be open at both ends to permit of through circulation and so as to prevent interference and congestion of traffic.

The elevators are of the special central-control type which has been used in several of the Army bases; that is, they are provided with an auxiliary mechanism which automatically levels the car floor at the level of the warehouse floor. A special dispatch central located in each building will have full control of all of the cars in the building.

On each of the three covered piers there are six elevators with a provision for six additional, to be installed at some future time. In addition, provision is made for spiral chutes from the second to the first deck.

In general, all traffic movements in the buildings and piers will be made by trailer trucks drawn by electric tractors. The average load of each trailer will be about 1500 lb., and they will be drawn in trains of from four to eight trailers in a train. At each floor, when receiving and discharging are in progress, there should be a continuous movement of loaded trucks in one direction and empty trucks in the other, between the point of loading or unloading and the elevators. The trucks will then be placed on the elevators and make continuous trips from point of loading to point of unloading and return—as, for example, for a storage space on an upper floor to the pier—but the tractor will move generally from point to point on its own floor. This results in three main circuits of travel for each group of elevators, proceeding simultaneously: (1) Between unloading platforms and elevators on the first floor; (2) between elevators and piers on the third floor; (3) between storage spaces on the upper floors and the elevators.

Normal Operation of Base

Normal operation of the base at a freight-handling unit is intended to be as follows: Incoming freight will be loaded on trailers and drawn by trucks to the elevator on the first floor. The door will then be closed and the car dispatched to the upper floor on which the goods are to be stored. When it reaches that floor the doors will be opened automatically, the trailers will be moved off by a tractor on that floor and replaced with empties. The doors will then be closed by the pressing of a button and the car returned to the first floor by the pressing of the dispatch button. Outgoing freight will be handled in similar fashion, the elevator with empty trucks being dispatched from the third floor to the loading floor, and the loaded elevator returning to the third floor. Special devices, of course, are provided whereby the elevators may be manually controlled, at which time the central dispatch system is thrown out of gear.

It is difficult to give full credit to all who are responsible for the rapid and effective construction of this mammoth project. The credit for initiative for its location and design should probably be given to Irving T. Bush, of the Bush Terminal Co., who early in 1917 began to study the problem of a big terminal in New York harbor. Its design was made by Cass Gilbert, New York architect, under the direction of Maj. Gen. G. W. Goethals, U. S. A., director of storage and traffic of the Army. The construction was carried out under the direction of the Construction Division of the Army, Brig. Gen. R. C. Marshall, Jr., chief of the division. The Turner Construction Co. of New York City is general contractor. In an organization chart prepared by the general contractor there are listed 36 separate subcontractors and fully a hundred responsible engineers and contractors' superintendents. In charge of the work for the Army as constructing quartermaster is Lieut. Col. H. S. Crocker, Quartermaster Corps, who before entering the service was a well known engineer of Denver, Colo. A. C. Tozzer is executive manager at the Army Base for the Turner Construction Company.

Canal Seepage Losses Are Affected by Temperature

Records Kept on Western Irrigation Project Show Increase of Losses with Warmer Water

By Lynn Crandall
Chief Hydrographer Twin Falls North Side Land & Water Co., Jerome, Idaho

THE effect of temperature on canal losses has not always been fully appreciated in studies made in the past, but it is a fact that the variation in temperature during the irrigation season may readily cause a 30% variation in the rate of seepage losses. The results of seepage investigations made early and late in the season must be considered in connection with water temperatures if information is desired regarding the loss at the time of maximum demand. In connection with detailed hydrometric investigations carried on for the past two years on the project of the Twin Falls North Side Land & Water Co. in southern Idaho, a fairly definite relation has been worked out between water temperatures and rate of loss; it is shown in the accompanying diagrams.

Fig. 1 shows the average monthly rate of loss over the entire canal system, comprising some 2600 acres of water surface. The results are based on daily records of use and supply, computed separately for each of the several hundred laterals on the project. The decreased rate of loss during 1917 compared with 1916 was probably due to the unusually silty character of the water during 1917. During August, 1917, when the demand was supplied almost entirely from storage, the water was quite clear and the rate of loss was the same as in 1916.

The losses are expressed in terms of depth lost per day over the water surface area, instead of the wetted perimeter, as commonly used. The water surface area is the easiest to determine, and probably the loss varies more nearly in proportion to it than to the wetted perimeter, as for conditions in ordinary canals the loss is mostly due to the action of gravity. For ordinary conditions on the North Side project the canal widths are about 5% less than the wetted perimeters, so the losses shown on Fig. 1 would be about 5% less if expressed in terms of the wetted perimeter.

Two storage reservoirs, Wilson Lake and Jerome Reservoir, are located on the tract. Wilson Lake, when full, covers an area of 1400 acres, with a storage of 18,000 acre-feet. Jerome Reservoir, if filled, would cover 5800 acres, with a storage of 60,000 acre-feet. On account of the excellent underground drainage, it has been impossible to build up the ground-water table underneath these reservoirs, and the present loss is nearly as

great as in ordinary canals in the same kind of material. This has rendered the reservoirs practically worthless for storage purposes. Wilson Lake is generally filled at the beginning of the irrigation season and used as a regulating basin for several months, but with the approach of the peak of the irrigation demand the large losses make it necessary to draw all water out of the reservoir and use it as a canal channel. No attempt is now made to fill Jerome Reservoir, but it has to be maintained at an elevation covering 400 acres, in order to furnish water to canals below.

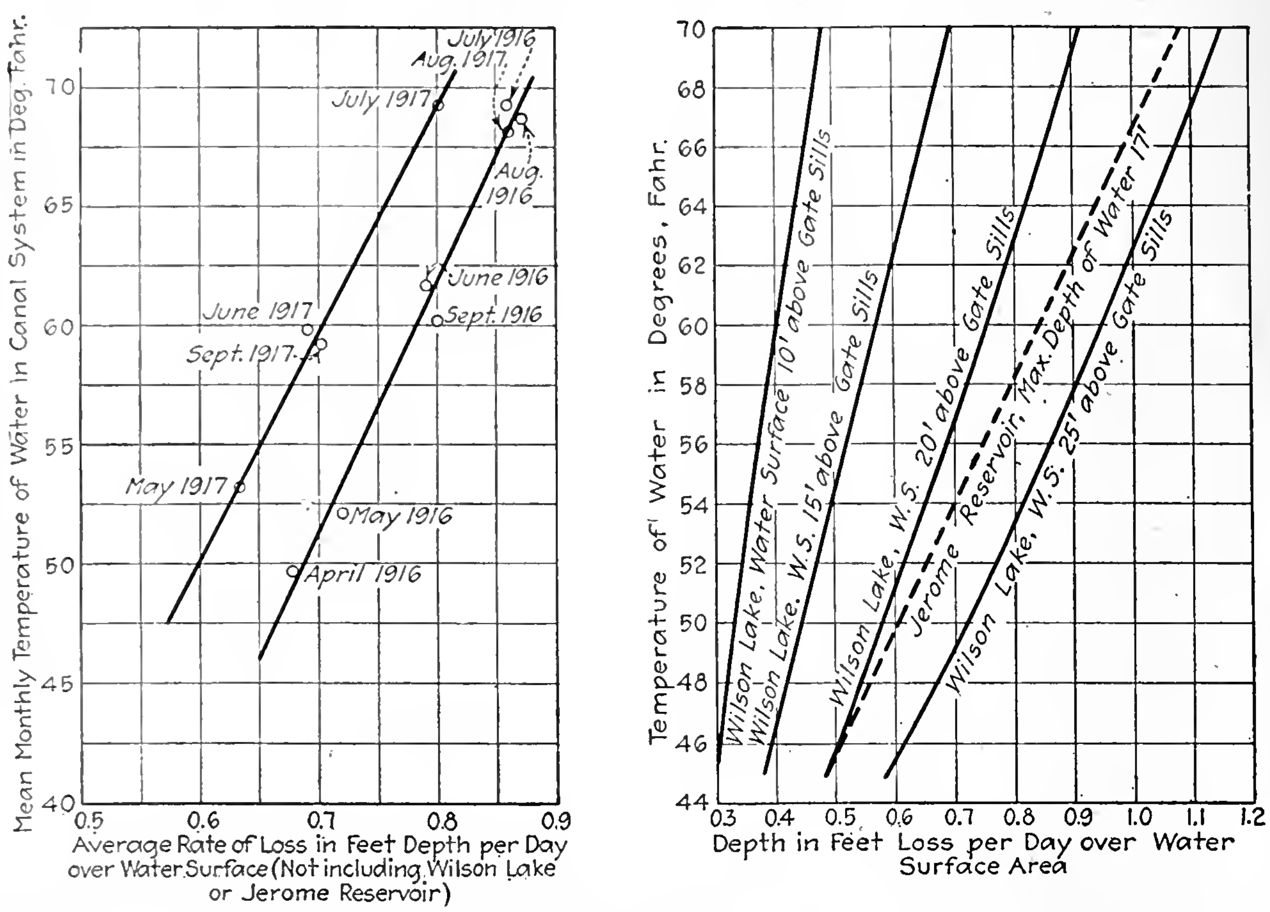


FIG. 1. RELATION BETWEEN SEEPAGE LOSSES AND WATER TEMPERATURE IN CANAL SYSTEM. FIG. 2. RELATION BETWEEN SEEPAGE LOSSES AND WATER TEMPERATURE IN WILSON LAKE AND JEROME RESERVOIR

Fig. 2 shows the losses for different water temperatures at various stages of Wilson Lake and at the height at which Jerome Reservoir is maintained. For the same depth of water the loss is somewhat less in Wilson Lake than in Jerome Reservoir, and the losses in the former increase rapidly with increasing depths. This is probably due to the fact that the bottom of Wilson Lake is largely composed of lava rock, which is more impervious to the passage of water than the deep, fine, sandy loam soil in the bottom of Jerome Reservoir and at the high elevations in Wilson Lake.

An interesting comparison between the seepage losses on the tract and the results obtained from ground-water flow formulas is given in the accompanying table:

TABLE SHOWING RATE OF LOSS AT VARIOUS TEMPERATURES COMPARED WITH RATE OF LOSS AT 45 DEGREES FAHRENHEIT

	Ratio of Loss to Loss at 45°		
Water Temperatures	50°	60°	70°
Hazen formula for ground-water flow	109%	128%	146%
Schlicter formula for ground-water flow	107	125	143
Loss in North Side Canal system, not including reservoirs; average, 1916-17	108	125	141
Loss in Jerome reservoir; maximum depth, 17 ft.	123	173	218
Loss in Wilson Lake; depth, 10 ft.	114	132	165
Loss in Wilson Lake; depth, 15 ft.	118	148	182
Loss in Wilson Lake; depth, 20 ft.	122	158	192
Loss in Wilson Lake; depth, 25 ft.	126	166	200

It will be noted that the actual canal seepage losses agree very closely with the results from the Hazen and Schlicter formulas for ground-water movement, but that the losses in the reservoirs show a greater proportional effect of temperature with increasing depths of water.

British Shipbuilding Below Production of 1913

Ship production in Great Britain during 1918 (in the year which ended Oct. 31) reached 1,600,000 tons, according to a statement of the Parliamentary Secretary of the Ministry of Shipping in the House of Commons Nov. 14. This is below the output reached in 1913, the kingdom's greatest shipbuilding year, when the production was 1,900,000 tons. The tonnages for four years, 1914-1917, are 1,700,000, 650,000, 540,000 and 1,200,000.

Cement Joints for Water Mains Save Money in Portland, Oregon

PORTLAND cement for making joints in cast-iron pipe is used by the Bureau of Water-Works of Portland, Ore., for all sizes from 6-in. to 30-in., except in some particular cases where it has been necessary to put the main in service without leaving sufficient time for the cement to set.

This practice was begun about three years ago, after a series of experiments, and gave such excellent results that it has been continued. During the past two years nine miles of cast-iron main have been laid, using 19,256 lb. of lead and 27,790 lb. of cement. A pound of cement will go as far as three pounds of lead, according to information furnished by F. M. Randlett, engineer for the bureau. With cement at ½c. per pound, the material for these joints cost $139. The same work would have required 68,390 lb. of lead at 8c. per pound, or $5470, therefore a saving of $5331 in material is shown.

It was thought at first that the labor of making the joints would be materially less for cement than for lead, but as the cement joints have to be kept wet for 36 to 48 hours the labor cost is about the same. In making the joints a small amount of yarn or oakum is first driven, to keep the cement from passing into the pipe. The cement is used neat, and only sufficient water is added to make it hold together while it is being forced into place.

Workmen at first showed considerable antagonism to this method of making joints, possibly because they believed their services might be reduced, but this has been overcome and the men have become skilled in making the cement joints.

Laboratory tests made at the University of Minnesota on cement, lead and metalium joints were noted in *Engineering News-Record* of May 23, 1918, p. 991.

Comparison of Formulas for Computing Parabolic Arcs

Limit of Applicability of Common Formula Defined—Exact Formula Simplified

BY ROBERT C. STRACHAN
Civil Engineer, New York

IN COMPUTING the lengths of parabolic arcs covering any considerable range in the ratio of rise to span, the engineer is called upon to reconcile discrepancies between different formulas, and to determine what is meant by a "small" ratio. While these questions may be academic when the actual dimensions do not exceed a few feet, they are of real weight in connection with long-span suspension bridges and transmission lines.

The commonly-used formula for the arc L in terms of the chord c and ratio k (rise divided by chord) is

$$L = c\left(1 + \frac{8}{3}k^2\right) \tag{1}$$

and usually a cautionary note is added, stating that this is true only for "small" values of k.

Investigation of the derivation of Formula 1 shows that beyond a certain limit, both this formula and the one of which it is an abbreviation are incorrect; the determination of this limit is then of prime importance.

Formula 1 is derived by integrating

$$\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{\frac{1}{2}} dx$$

after expanding by the binomial theorem, as follows:

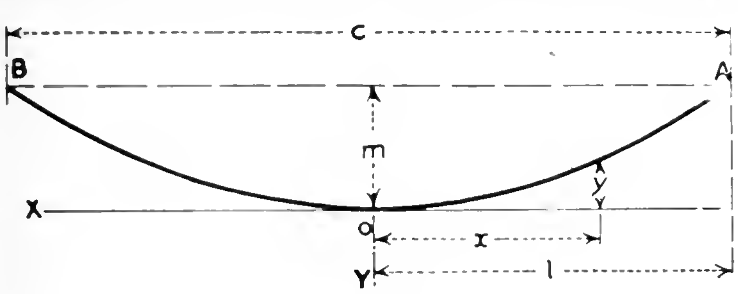

FIG. 1

$$y = \frac{mx^2}{l^2} \therefore \frac{dy}{dx} = \frac{2mx}{l^2}$$

and if L = arc BOA

$$L = 2\int_0^l \left(1 + \frac{4m^2x^2}{l^4}\right)^{\frac{1}{2}} dx \tag{2}$$

Expanding and integrating, representing the element of arc by ds, we obtain

$$\int_0^l ds = l + \frac{2m^2}{3l} - \frac{2m^4}{5l^3} + \frac{4m^6}{7l^5} - \frac{10m^8}{9l^7} + \frac{28m^{10}}{11l^9} - \ldots$$

Substituting for l its value $c/2$ and for m/c the symbol k, we have, finally, in notation coinciding with that used in (1)

$$L = 2\int_0^l ds = c(1 + \frac{8}{3}k^2 - \frac{32}{5}k^4 + \frac{256}{7}k^6 - \frac{2560}{9}k^8 + \ldots) \tag{3}$$

The expansion from which results Formula 3 is a legitimate method by which to transform an expression of the form

$$\left(1 + \frac{r}{q}\right)^{\frac{1}{2}}$$

into a series; but the series thus obtained fails to converge if r/q is greater than unity. Applying this criterion to the second term of the binomial in (2), recollecting that x becomes l at the upper limit, we find

$$\frac{m}{l} < \tfrac{1}{2} \therefore k < \tfrac{1}{4}$$

Formula 3 therefore fails to give the true value of L however great the number of terms computed unless k is equal to or less than $\frac{1}{4}$: that is unless the chord c is between the focus and the vertex. The degree of approximation attained in different regions as k varies between 0 and $\frac{1}{4}$ will be considered after deriving a second formula for the length of the arc, the results of which will serve as a basis for comparison.

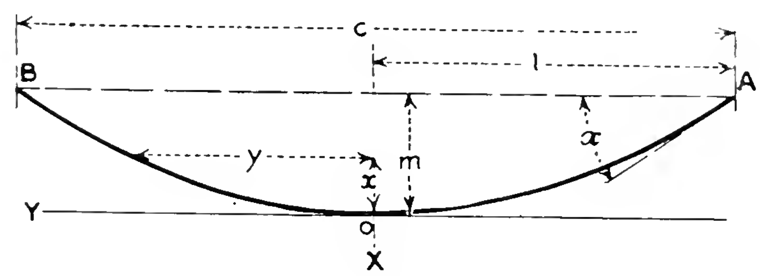

FIG. 2

Referring to Fig. 2, and writing the symbol a for the distance from vertex to focus,

$$y^2 = 4ax \therefore \left(\frac{dy}{dx}\right)^2 = \frac{a}{x} \text{ and } ds = \left(\frac{x+a}{x}\right)^{\frac{1}{2}} dx$$

Hence

$$\int ds = \sqrt{x(x+a)} + a \log_e(\sqrt{x} + \sqrt{x+a}) + C$$

and

$$Arc\ OA = \int_0^m ds = \sqrt{m(m+a)} + a \log_e\left(\frac{\sqrt{m} + \sqrt{m+a}}{\sqrt{a}}\right)$$

which is equivalent to

$$Arc\ OA = a\left[\sqrt{\frac{m}{a}\left(1 + \frac{m}{a}\right)} + \log_e\left(\sqrt{\frac{m}{a}} + \sqrt{1 + \frac{m}{a}}\right)\right]$$

From the equation of the curve, $l^2 = 4am$; therefore

$$a = \frac{c^2}{16m} = \frac{c}{16k} \text{ and } \frac{m}{a} = 16k^2$$

After these substitutions have been made the expression for the length of the arc BOA will appear in the well-known form

$$L = \frac{c}{2}\sqrt{1 + 16k^2} + \frac{c}{8k}[\log_e(4k + \sqrt{1 + 16k^2})] \tag{4}$$

which is true for any value of k.

Formula 4 may be made more concise by introducing the hyperbolic functions.

If we denote the tangential angle at A or B by α and its antigudermannian by u, then

$$\tan \alpha = 4k = \sinh u \qquad \sqrt{1 + 16k^2} = \cosh u$$

$$\log_e(4k + \sqrt{1 + 16k^2}) = u$$

and the expression for the arc will therefore be

$$L = \frac{c}{16k}(2u + \sinh 2u) \tag{5}$$

A comparison between the values of L/c obtained from the three formulas will indicate the percentage of error involved in the use of (1) or (3), and the process of obtaining the results will show the greater conciseness of (5).

Example 1. Let $k = 0.2$; then,

By Formula (5)

$$\begin{array}{rl} & 4k = 0.8 = \sinh u, \text{ and,} \\ \text{from table,} & 0.73267 = u \\ & 1.46534 = 2u \\ \text{from table,} & \underline{2.04901} = \sinh 2u \\ & 3.51435 \div 16k = 1.09823 = \dfrac{L}{c} \end{array}$$

By Formula (1) *or* (3)

$$\begin{array}{rlll} 1 + \tfrac{8}{3}k^2 = & 1.10667 & & \\ 6.4k^4 = & -\ .01024 & 1.09643 & \text{3 terms} \\ 36.57k^6 = & +\ .00234 & 1.09877 & \text{4 terms} \\ 284.44k^8 = & -\ .00073 & 1.09804 & \text{5 terms} \\ 2606.55k^{10} = & +\ .00026 & 1.09830 & \text{6 terms} \end{array}$$

Example 2. Let $k = 0.1$; then,

By Formula (5)

$$\begin{array}{rl} & 4k = 0.4 = \sinh u, \text{ and,} \\ \text{from table,} & 0.39004 = u \\ & 0.78008 = 2u \\ \text{from table,} & \underline{0.86163} = \sinh 2u \\ & 1.64171 \div 16k = 1.02607 = \dfrac{L}{c} \end{array}$$

By Formula (1) *or* (3)

$$\begin{array}{rlll} 1 + \tfrac{8}{3}k^2 = & 1.02667 & & \\ 6.4k^4 = & -\ .00064 & 1.02603 & \text{3 terms} \\ 36.57k^6 = & +\ .00004 & 1.02607 & \text{4 terms} \end{array}$$

Example 3. Let $k = 0.01$; then,

By Formula (5)

$$\begin{array}{rl} & 4k = 0.04 = \sinh u, \text{ and,} \\ \text{from table,} & 0.039988 = u \\ & 0.079976 = 2u \\ \text{from table,} & \underline{0.080065} = \sinh 2u \\ & 0.160041 \div 16k = 1.00026 = \dfrac{L}{c} \end{array}$$

By Formula (1) *or* (3)

$$\begin{array}{rll} 1 + \tfrac{8}{3}k^2 = & 1.00027 & \text{2 terms} \\ 6.4k^4 = & -\ .00000 \ldots & \end{array}$$

It appears from these examples that for values of k near 0.01 Formula 1 may be depended upon to the fourth decimal place, and farther as k grows smaller. For values of k near 0.1 Formula 1 is accurate only to the third decimal place; and not less than four terms of the series of Formula 3 must be computed to insure accuracy in the fourth place. For values of k considerably above 0.1 Formula 1 is a comparatively rough approximation, and Formula 3 is cumbersome because of the large number of terms which must be computed to insure accuracy even in the third decimal place. Formula 3 is of course useless for all values of k above or slightly below 0.25.

Formula 1 may then be said to be sufficiently accurate for practical purposes for most cases in which k is 0.01 or less. Formula 5 is preferable whenever k is greater than 0.01, if hyperbolic tables of suitable range are available. If not, Formula 4, which is merely another form of (5) though more time-consuming in its application, may be substituted.

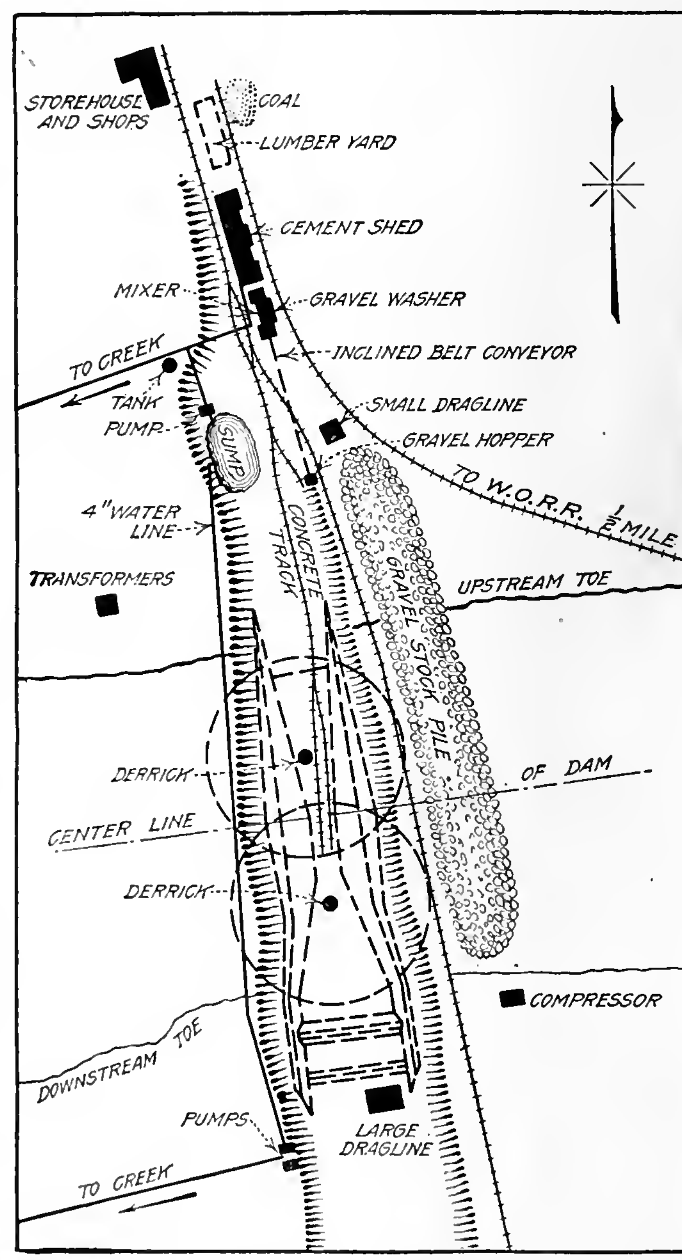
Large Increase in Motor-Truck Traffic

Motor trucks in New York State during the past year increased from 55,402 to 75,268 or 36 per cent., according to Secretary of State Hugo. A similar increase in 1919 would add over 27,000 trucks. Reports state that this will be considerably exceeded. Of the total number of trucks mentioned above about 32,000 are registered from New York City, an increase for the year of 7000.

Mammoth Derricks Build Concrete Outlet for Lockington Dam

Gravel from Excavation Washed and Screened for Concrete — All Operations Mechanical from Pit to Forms

TWO electrically-operated guy derricks of unusual size are concreting the 38,000-cu.yd. outlet and spillway structure for the Lockington Dam of the Miami flood-control works. With 120-ft. masts and 105-ft. booms these derricks cover the full 140-ft. width of the structure and reach its full height of 82 ft, handling both concrete and forms. Concrete is brought by rail to the derricks from a gravel-washing and concrete-



COMPACT LAYOUT KEEPS HAUL DISTANCE MODERATE

mixing plant of the standard type adopted by the flood-control engineers and described in *Engineering News-Record* of Oct. 10, 1918, p. 680.

Lockington Dam is an earth structure about 7000 ft. long, 440 ft. thick at the base and 74 ft. high. The concrete spillway and outlet structures, extending through the embankment, consists of two side walls about 500 ft. long parallel at the center and flaring out at the ends, as indicated by the dash lines on the plant layout map. The walls are 82 ft. high and are 140 ft. apart, out to out. Between the walls is a floor of concrete, and at the center is a cross wall having two 9 x 9-ft. 2-in. openings through which the river waters will normally find outlet The space above the cross wall and between the side walls, which are 82 ft. high, forms the

DERRICKS TOWERING ABOVE WALLS REACH ALL PARTS OF LOCKINGTON DAM OUTLET STRUCTURE

spillway for extraordinary floods. In the plan of construction the cross wall will be built last, so as to afford a clear channel for the stream during the construction of the dam embankment.

Where the concrete spillway and outlet are being built, a remarkably level bedrock occurs only a few feet below the stream bed. Excavation of only a foot or two of the surface is necessary to reach solid rock on which the concrete can be laid. Above the rock is gravel covered with earth. Very little water is carried by this overburden. The gravel, moreover, is entirely suitable, after screening and washing, for use in concrete, and as the channel for the concrete structure is excavated, the earth is piled to one side and the gravel is stored at the other side for future use. A dragline excavator is excavating the channel.

The plant layout for the spillway construction is shown by the map and by the view looking south. Beginning at the north end, the large dragline worked south, excavating the channel, depositing the earth in the west bank and piling the gravel on the east bank. The routine of handling materials and concrete is then as follows: A standard-gage service railway, as shown by the map, runs along the east edge of the cut, and between it and the gravel pile and alongside the gravel hopper of the washing plant. Gravel is transported in 4-cu.yd. dump cars hauled by dinkeys. While the large dragline is still excavating the cut it dumps the gravel directly into the cars, but when the excavation is finished the cars will be loaded from the gravel pile by means of the small dragline.

Gravel cars dump into a ground-level hopper, where a grizzly separates out the large stones, and whence the fine material feeds onto an inclined belt conveyor leading to the screens and washer. The screens separate the washed gravel into coarse and fine gravel and into sand, and discharge each size into a compartment of an elevated bin over the mixer. Close to and in line with the bin is the cement house, to which a service track connecting with the Western Ohio Electric Ry. delivers the cement cars. Structurally the cement house and bins are duplicates of those described in *Engineering News-Record* of Oct. 10, 1918, p. 680, and the mechanical equipment is the same.

The water for washing the gravel is supplied by seepage into the cut. The water which seeps from the north end is collected into a sump and thence is pumped to the screens. If this supply pulls short, water from seepage from the south end is pumped to the sump. All surplus ground water and waste water from the washers are discharged to Loraine Creek, running roughly parallel to the cut and west of it. Water for mixing is taken directly from the line to the gravel washers, and a reserve supply is stored in the tank.

Service tracks of 30-in. gage passing under the mixer discharge extend along the bottom of the cut to the derricks. Three two-car trains hauled by gasoline locomotives deliver the concrete. The cars are small platform cars, each carrying a 1¼-cu.yd. bottom-dump bucket. The buckets are lifted to the forms by the derricks. The derricks also handle the sectional forms and the plum stones which are embedded in the concrete.

Most of the plums are stones separated from the gravel by the hopper grizzly. These stones are hosed clean, loaded into concrete buckets and, like the concrete, are taken by cars to the derricks.

The subsidiary plant, such as the lumber yard, the shops and the compressor house and its rail connections, is explained by the map. Except the dinkeys, all machinery is operated by electricity.

Lockington Dam is a part of the flood-control works of the Miami Conservancy District. Arthur E. Morgan is chief engineer, Charles H. Paul is assistant chief engineer, and C. H. Locher, construction manager. Barton M. Jones is division engineer in charge of the dam.

Opportunities for Chicago Engineers to Work Together

Combined Activities in Actual Practice Needed—Low Wages, Unemployment and Reconstruction Challenge Attention

By C. E. Drayer

Secretary of the American Association of Engineers, Chicago

At the onset of the world conflict, business and industry were immediately marshalled by the United States Chamber of Commerce into the most powerful voluntary instrumentality in the United States for winning the war. It kept these forces mobilized for the problems of peace, by the great conference at Atlantic City. Are our engineers big enough to cease weighing progress in the balance of prejudice, and can they get together and do collectively the works of peace with something of the brilliant success of the individual engineer in the war?

Organized to mobilize engineers of Chicago to help win the war, the War Committee of 19 Chicago technical societies must now either disband or direct its activities into channels where they will be useful to the constituent societies in times of peace. In discussing the possibilities of future work, the suggestion was made that the War Committee offer its services to the engineering societies' employment bureau, for the establishing of a branch in Chicago.

The War Committee placed directly, in the six months of its existence, from 50 to 75 men. During the same period the Division of Engineering of the United States Employment Service placed some 5000 engineers, and the Service Clearing House of the American Association of Engineers from three to five men a day. Setting up another engineering employment agency in Chicago would lead, therefore, not to integration but disintegration of existing agencies. This is a step backward. The principle should be *combined engineering organization for effective service to the entire profession.*

All engineering societies are preaching coöperation. Why not put it in plain English and get busy and work together? Only when organized engineering gives employment service in a more effective way than the leeching private agencies can we hope to compete so successfully with them as to put them out of business. Unless we give better service, they will continue to thrive, sucking from the unfortunate engineer who is out of employment from 50 to 60% of the first month's salary. Unless those in charge of the direction of engineering societies do get together and perform employment service, especially in the uncertain times at hand, we shall merit the censure of inefficiency. The need is for even a more vigorous and comprehensive performance than the Division of Engineering was able to deliver.

The argument is that either the Service Clearing House of the American Association of Engineers should be unselfishly supported by all, or all engineers should get unreservedly behind the Division of Engineering of the United States Employment Service, another going organization. Employment must be cared for *now,* and the work must be well done.

Let the War Committee take up some of the many things challenging attention of engineers collectively. The wages of engineers in Chicago have not been raised for 20 years. Here is a job for the 8000 engineers in Chicago. How about the administration of the $60,000,000 bond issue for good roads in Illinois? Why not have an engineer experienced in politics at the constitutional convention soon to be held in Illinois? Where are we engineers to take our place in the great reconstruction problems? Another society employment service in Chicago means "carrying coal to Newcastle," in view of the many things challenging our best efforts.

Another phase of the employment situation involves developing work where none exists. In other words, why should not the engineer be the chief promoter, particularly in the field of public works? If, by spending one dollar for good roads, two dollars are returned to the investing public, why shouldn't the engineer be the first to demonstrate this to his employer, the public? There are other fields for equally profitable exploitation. It is almost a maxim in the business world that, where demand does not exist, it may be created by advertising.

Still another phase of the employment situation concerns the study of salaries that are paid and that should be paid. The profession is being invaded right now by unionism, by the formation of a draftsmen's union as a branch of the American Federation of Labor (see *Engineering News-Record* of Jan. 23, 1919, p. 201). Such things do not happen without good cause. It is probable that hardly any engineers now in union ranks receive as much as $2500 per year, with an average of much less. In other words, the reason seems to be that our engineering societies have failed to face fearlessly the wage-problem phase of the profession, with the result that the men in the lower-paid positions are willing to try another agency.

Here is an indictment of our failure in getting together. How long will the rank and file of the profession permit these conditions to exist?

Pennsylvania Labor Turnover 100 Per Cent. Yearly

In a 10-day period recently 4477 employees left the divisional forces of the eastern lines of the Pennsylvania R.R. and 5122 new ones were hired, stated a bulletin issued by Elisha Lee, Federal manager. The net gain of 645 occurred entirely in the last two days of the period and was apparently sporadic. During the period the number of women employees increased 1545—from 5682 to 7227—while the number of men employees decreased 900. As the total divisional forces had been averaging between 148,000 and 150,000, the bulletin pointed out that the 10-day test indicated a turnover of about 100% per year.

What About the Government Housing Program?

Engineers Should Be Active in Study of Housing in General and of Solution of the Problem of Disposing of Those Government Projects Already Under Way

By Morris Knowles
Chief Engineer, Division of Passenger Transportation and Housing, United States Shipping Board, Emergency Fleet Corporation, Philadelphia

As a necessary war measure, the United States Government about a year ago entered into extensive housing operations which were only partly completed when the armistice was signed. Now that the immediacy of the demand has passed, there is much clamor of one sort or another for the shutting down forthwith of all such operations and the closing out of the whole Government experiment in housing. Engineers have not, as a rule, paid to this problem the attention it deserves. The present article is intended to stimulate thought in the profession which should be most vitally concerned with housing.

Two Government bodies conducted housing operations; one, the Emergency Fleet Corporation, with an appropriation of $75,000,000, for the purpose of housing shipyard workers and their families; the other, the United States Housing Corporation, a bureau of the Department of Labor, with an appropriation of $110,000,000, which has planned towns for the accommodation of munition workers and those engaged in similar war activities other than shipbuilding. The work of these agencies was brought about by a war necessity. Generally, the question was not alone one of improving a sociological condition; men simply could not be induced to work in the munition plants or shipyards where there was a more or less complete lack of houses to live in; and the labor overturns resulting amounted to as much as 700 per cent. per month in some plants. But, as in certain other war-time activities, the results that either have been or may be accomplished by these agencies give promise of solid and enduring benefits in the arts of peace.

What Has Already Been Done

About 90 separate industrial housing projects, to house approximately 150,000 persons, were contemplated by the United States Housing Corporation, and about one-half of these had been placed under contract at the time of the signing of the armistice. Thirty community housing projects are being built by the Division of Passenger Transportation and Housing of the Emergency Fleet Corporation; most of these are complete towns, of from 240 to 7000 contemplated population, while the total population to be served amounts to about 55,000. The aim of these departments has been to create convenient, healthful and attractive living quarters for the workingmen and their families, at an expense consistent with good business judgment. The results, where they have been permitted to come to realization, have been generally in strong contrast to dreary, unappealing laborers' tenements, built in the habitual cramped, stereotyped rows, dingy, squalid, and too often lacking in the first requisites of cleanliness and good sanitation.

The end of the war found these activities with some building work completed, many things accomplished, and much of importance yet to be done. Shortly after the signing of the armistice a resolution was introduced at the convention of the United States Chamber of Commerce, assembled at Atlantic City, which sought to declare in favor of Government abandonment of its housing projects. The United States Senate, anxious to curtail expenditures instantly, provided shortly thereafter in a sweeping resolution. (S. J. Res. 194)

> That the United States Housing Corporation . . . be, and hereby is, directed to suspend work upon all buildings on which it is now engaged in all cases where the construction is not more than 75 per centum completed.

This action was followed by numerous protests, among which is that of the American Civic Association, which by its executive board stated, Dec. 9, 1918:

> The association holds that where these projects are situated in communities urgently in need of additional housing to meet post-war conditions . . . . the proper course for the Government is to complete the projects without interruption . . . . and then to dispose of them in an orderly, deliberate manner; except only in those cases where the Government can clearly obtain a greater net salvage by immediate abandonment and liquidation.

The association further holds that the arbitrary cancellation of existing contracts both with builders' organizations and with public service corporations and municipalities involves a serious economic loss; both actual, in the throwing away of that which has been done; and potential, through loss of expected benefits. Such protests have been effective in bringing about a substitute resolution of the House Committee, under the same name (S. J. Res. 194), which orders the completion of 24 of the projects and further proposes that the Secretary of Labor make to Congress recommendations and suggestions to meet the demands for homes for the citizens of the United States.

The question now is, Shall Government activities be continued and the initiation of successful management be the goal?

Projects Call for Different Answers

It is evident that different stages of progress in the various housing projects call for separate answers in different places, dependent upon the needs. Many situations exist where the investment is so large and the need of houses still so great, the opportunity for wise management in starting operations so opportune, and the waste so great which would come from stopping now, that good business judgment means the keeping of control until some favorable method and opportunity can be found for sale or disposal otherwise. No general rule can be laid down; the decision must rest upon the facts presented in each case. Surely, the engineer, in his new realization of citizenship, will be not less than alert to his opportunity to promote sound thinking and wise planning for the future, by insisting that the present occasion be used to the utmost to demonstrate

what wise and honest endeavor can do to prevent labor shortage and turnover. It is necessarily a matter of good judgment to determine the nice balance of economics between the salvage to come from abandonment, and the estimated results to come from the sale of completed projects, which in turn demands an intelligent estimate of the need, and the continuance of such need as a post-war condition.

Community Gain the Critical Element

It is unnecessary, even were space available, to present here the case for better housing conditions. Much has been said and written elsewhere on that subject, and it surely will be realized that the question of housing and living conditions is an important one in our future industrial life. The question, then, is not so much whether our Government organization, or one or more of its various agencies, shall save money out of its appropriation; nor is it a question of individual loss or gain. The real question is whether the community as a whole shall realize the full advantage from the already large expenditure made for the Governmental housing developments. In other words, the question is one of loss or gain in economy to the entire country, and not to one of its creatures.

Of secondary importance, perhaps, but none the less of real concern to the engineer, will be the stultifying effect upon the subject of correct housing which surely will ensue from arbitrarily stopping in many places the first comprehensive housing projects to be undertaken in the country on so large a scale. The practical results of many aims are at stake. It is plain, and probably needs no argument, that the projects now started, if abandoned, will now and for a long time in the future present a stumbling block in the particular community, as an example, to be quoted by some, of alleged insecurity and bad policy of the paternal care of labor. Notwithstanding this, there will be many who will think that the work should now be stopped rather than to continue to "sink good money after bad."

Advocates and opponents should not confuse the housing situation with that relating to Government ownership or landlordism, for the question of permanent Government control and management with the necessary acceptance of such paternalism is not before us now; even the most radical are not proposing this. Nor does the advocacy of continuing the present projects until they are going concerns savor of or favor Government ownership of public utilities *per se*. Nor should it be considered as equivalent to the much mooted proposition to continue the control and operation of the railroads, telephone or telegraph lines for the next five years. The former is an undertaking stated to be a war measure for the transportation of soldiers and materials for fighting purposes only; and, in the case of the latter, such facilities were also taken over as an emergency measure, with the understanding that return should take place as soon as the emergency is past. The utilities can be turned back to those agencies, long created and familiar with their duties and with the correct handling of their problems without the necessity for building new organizations. It is not so with housing. New agencies must be established in many cases, and can be successful only after careful and thoughtful consideration, and as a result of some experience. It must be remembered, however, that the danger of Government ownership, operation and control of workmen's homes, without a well considered program being developed, may open the way to a wasteful, political, paternalistic policy respecting certain institutions, industries, workmen and the occupants of the dwellings, and involve practices with regard to rentals and welfare activities which will saddle the Government with a policy not yet determined and approved.

There are, too, differences in the fundamental arrangements among the several projects already started which need careful consideration. For instance, in most of the housing developments of the Emergency Fleet Corporation the shipbuilding company, through a realty corporation, has provided the land without cost to the Government. Thus it has an equity in the proceeding, an interest and a privilege to take over the project and repay to the Government the investment made less the write-off due to excess war cost, as determined by appraisal; such amounts to be paid in 10 annual installments with interest of five per cent.

It is evident from the foregoing that decision should not be reached post-haste or as the results of any preconceived opinions. For instance, a loading-plant in the wilderness, never possible for any other use and perhaps only partially completed, will be considered differently than the shipyard likely to be permanently used in commercial maritime work, and whose need has always been felt and will continue.

What Is the Engineer's Interest?

It appears, therefore, that there is not only at stake a large part of the value of $185,000,000, but also the welfare of an important branch of engineering and its beneficial effects on labor. The interest of the engineer in this proceeding is self-evident. He is interested, first, as a public-spirited citizen in seeing that the community as a whole derives the utmost benefits from the work already done and the expenditures already made. He is also interested in seeing to it that no prejudice results to an important branch of his profession from arbitrary or ill considered legislation.

The determination of whether a given community development should be completed or not, necessarily involves more than consideration of the question of house building, for suitable and adequate facilities for water-supply, sewer, gas and electricity, highways, walks and transportation—all engineering features—are needed to make a town livable. It is no wild flight of the imagination to see beautiful and attractive houses, pleasantly grouped under shady trees, that remain unoccupied because there is a lack of street paving and walks, with failure to grade lots and gutters, resulting in muddy tracking of nice hardwood floors, and also in mosquito-breeding pools in the back yards.

Nor should the engineer be less interested in the complete communal development, such as provision for zoning, stores, schools, churches, and recreation areas, grading of yards, reasonable planting, and the initiation of those neighborhood facilities which promote agreeable social and community life. And it is not answering to say that private initiative, group arrangements by

those who live in a common block, or municipal endeavor, under taxation methods, will be a solution; for the new community finds many ways to use the public moneys and the subscription method is resorted to for many fields, and is usually overdone. In specific cases, however, certain of the group and communal activities may well be left to private initiative, on the basis that something must be left for people to do for themselves.

Too often has the engineer been subordinated in such community planning and development, partly because building houses is the primary purpose and the creation of the architect, which has resulted in a forgetfulness that the engineering questions of street layout, drainage, adequate and safe water-supply and disposal of wastes, are important and vital matters of such an enterprise; and, partly, it must be confessed, because the engineer, with his modesty and desire not to appear too prominent in the discussion of such enterprises, does not let it be known that he, too, is interested in other than plain houses, and that he, too, has a soul and likes to live in attractive, comfortable and convenient community developments.

Constructive criticism should be most apropos. A clear statement, based upon sound business judgment—a matter upon which the engineer should insist—is offered in the following program:

1. A project situated in such a place that during post-war conditions it will fill a demand for more housing facilities, should be completed as promptly as possible.

2. A project where salvage coming from abandonment and liquidation will not exceed the return which would come from sufficiently completing it in an orderly and deliberate manner, should also be completed.

3. The degree of completion must depend in each case upon the facts, and may or may not include all communal facilities. Certain facilities, however, are needed in order that a correct start as a going concern may be obtained.

4. Arbitrary cancellations of projects based only upon percentage of completion, without consideration of other factors, will generally be unwise and uneconomical.

5. Plans for continued operation should, in the absence of a definite Governmental policy, be approached with careful consideration of the influence upon the welfare, both of the worker and of industrial concerns, and possible discrimination, due to the advantageous situation of those favored by Governmental participations, should be guarded against.

6. On the other hand, a belief in complete failure of such endeavors should be avoided, by the institution of a wise program calling for management until a going concern is obtained; with an endeavor to turn over to existing agencies as soon as this result has been gained. Obviously, paternalism must be avoided.

United States Water Laboratories in France

NONE of the 48 officers and 69 enlisted men operating the water-analysis laboratories in France is on an early list to return home, according to Lieut.-Col. Edward Bartow, senior officer, formerly director of the Illinois State Water Survey. It is expected that the work in the Service of Supplies will continue for some time in the camps of concentration and embarkation.

Lieutenant Colonel Bartow's first service in France on his arrival, in October, 1917, was under the French Interministerial Commission, by which he was assigned to work in the laboratory of Prof. Louis Lapicque, *Laboratoire Muséum Histoire Naturelle*, on water sterilization by liquid chlorine. Tests made on the raw Seine river water formed the basis of a 30-p. article in the *Revue d'Hygiène* for January-February, 1918. This was reprinted and used by the engineers and sanitary corps officers of the United States Army to explain the process to the officials of French cities in which liquid-chlorine machines had been installed, including Brest, St. Nazaire, Savenay, Tours and Dijon.

Since March most of Lieutenant Colonel Bartow's work has been the organization and supervision of the laboratories of the Service of Supplies and the sanitary control of the water-supplies furnished by the engineers to the armies. Five mobile laboratories have been operating with the armies, and laboratories were established in Paris, St. Nazaire and Tours, France, and in Winchester, England.

Because of the necessity for speed and uniformity in obtaining results, the methods of the American Public Health Association, the American Chemical Society and the United States Treasury Department (Health Service) were adapted to the conditions existing in the American Expeditionary Forces, and were published in bulletin form.

The duties performed by the laboratory staffs included sanitary surveys of occupied areas; bacterial and chemical control of filter plants operated by the United States Army; industrial analyses of waters used in locomotives, laundries and airplane motors, and a comprehensive study of water supplied to troops in transit, leading to a recommendation for the addition of the requisite number of faucets, and facilities for sterilization.

Coal Saved by Electrifying Railroads in Italy

Saving in the use of coal has been effected in Italy in the past few years through the electrification of railroads and the harnessing of the water power of the country to generate electricity. The percentage of railroads electrified in Italy from 1900-1915 is greater than in any other European country. Electric traction of railroads began in Italy in 1900 with installations on the Varesina line, which runs through Milan, Gallarate, Varese and Ponteceresio, and on the Valtellinese line, which runs from Lecco to Chiavenna. Railways which run on mountainous routes and carry heavy trains are the Moncenisio line, the Ceva-Port Savona line, the old line of Giovi and the new supplementary Giovi line. The Moncenisio line is the longest—8.5 miles long, at an altitude of more than 1000 yd. above sea level, continuously on the ascent. The systems installed on these mountain routes increased the carrying capacity and the speed of the railways. There is at present under consideration the electrification of 1250 miles more.

Inland Ship-Steel Fabricating Plants of the Emergency Fleet Corporation

Shops at Pottstown and Leetsdale for Fabricating Hog Island Material, Designed To Produce 10,000 Tons Per Month Each, Are Laid Out for Straight-Line Movement of Material Through Five Aisles

By Leyburn G. Fishach
Authorized Representative, Emergency Fleet Corporation, Leetsdale, Penn.

STRUCTURAL-STEEL shops have fabricated a large tonnage for the shipbuilding program of the Emergency Fleet Corporation. Yet there are certain radical differences, between ship work and bridge or structural work, due principally to the large percentage of bent frames and wide plates characteristic of hull steel. These features affect not only the type and capacity of the equipment, but also the arrangement and spacing of the machines in the shop. Two great ship-steel fabricating plants which have been built for the Emergency Fleet Corporation by the McClintic-Marshall Construction Co. of Pittsburgh, Penn., are therefore strikingly different from bridge shops. They were laid out to suit the classifications of work represented in hull steel and give proper balance of the several departments.

One of these plants is at Pottstown, the other at Leetsdale, Penn.; each will have a capacity of 10,000 tons per month when in full operation and will fabricate for the Hog Island Shipyard. They are of the same general design, but in plan are of opposite hand. The following description applies specifically to the Leetsdale shop.

The plant consists of a single shop-building, with receiving yard at one end and shipping yard at the other, all planned for direct straight-line travel of material. The building is 594 ft. long, 390 ft. wide for half the length and 310 ft. for the remainder. It is one story in height, and has steel framing, brick walls, wood sheathing covered with asbestos, and steel sash in both outer walls and roof lights.

The roof construction is of the familiar high-and-low-bay type (see the view, Fig. 1), the bays running across the building. The high bays are 47 ft. wide, the low bays 23 ft.; this alternation of spaces was adopted to reduce the cantilever of the cross-travel cranes. Except for a small area of cement floor at riveter runs and clay floor in the forge shop, the floor is made of 1⅝ x 6-in. maple laid on 4 x 6-in. chestnut sleepers over a 4-in. concrete foundation. All the exposed steelwork and brickwork on the interior of the building, down to within 8 ft. of the floor, is painted white, to improve the interior lighting, as is also the under side of the roof sheathing.

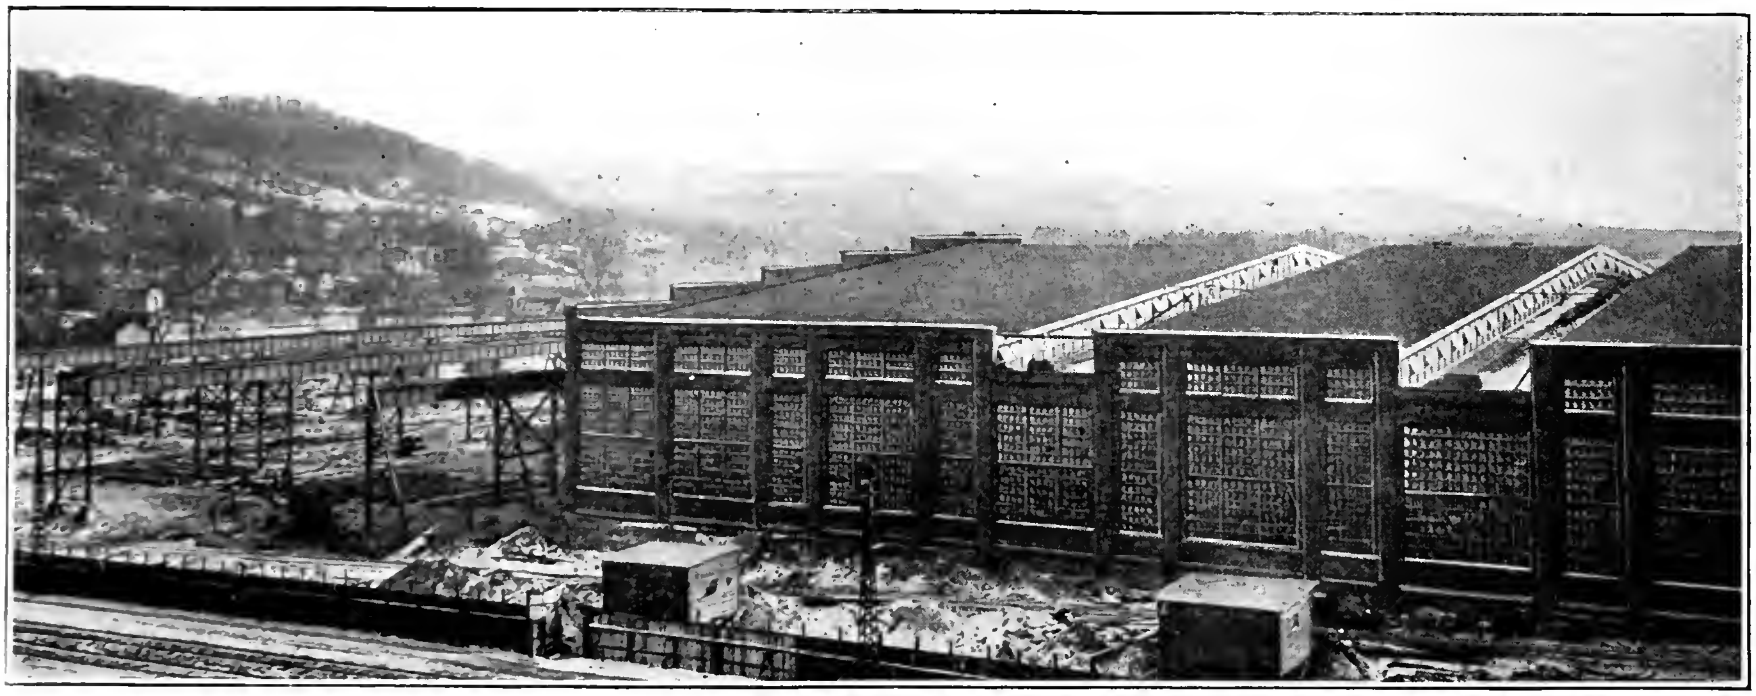


FIG. 1. RECEIVING-YARD END OF LEETSDALE SHOP—AMPLE GLAZING FOR GOOD INTERIOR LIGHTING

Continuous forward movement of ship steel will begin in the receiving yard and terminate in the shipping yard, at opposite ends of the building. These yards are 510 x 210 ft. each, placed at right angles to the building. They consist of two 80-ft. aisles, formed by runways for five-motor electric traveling cranes of 20 tons capacity, with 28-ft. height of lift; each aisle has one crane. Adjoining the receiving yard is additional storage area of 70,000 sq.ft., served by locomotive cranes.

Raw material in the receiving yard is stored opposite the shop aisle in which it is to be fabricated. It is thus most easily reached from the narrow-gage tracks which run down the center of each aisle and, as the stock is close to the machines, delays in getting the steel to the operator are minimized.

This latter effect is aided by the arrangement of the outside trackage, which prevents the interruptions to the shop program that would result from unnecessary handling of the raw and finished steel. A double line of tracks extends the full length of the site on each side of the building, and passes under the end spans of the receiving and shipping yard runways. A fifth line crosses the receiving yard and enters the shop. The entire system of trackage within the lot lines has a

total length of 5700 ft. It is connected with a siding 1200 ft. long adjacent to the main line of the Pittsburgh, Fort Wayne & Chicago Railroad.

Shop Division to Suit Fabricating Equipment—The desired arrangement of the fabricating equipment determined the length of spans of the trusses across the building, and divided the floor area into five aisles between the longitudinal column rows. The center aisle is 70 ft. wide, the other four 80 ft. each. These five aisles constitute separate shop units, equipped to act independently in the fabrication of their respective classes of ship steel: Furnaced and forge work, plate and angle work, and beam work. But as the plate and angle work requires more floor area than the other two classes, it occupies the three interior aisles, though there are subdivisions within that area for convenience in handling the steel. This unit system prevents backward motion of material and reduces cross travel into other aisles, so that it is a determining element of economical operation.

Transverse Crane System—The crane system within the building is contrary to the usual practice in that all cranes operate across the shop or aisle, while forward motion through the entire length of the building is by means of steel-framed trucks on an industrial track in the center of each aisle. One cross-line with turntables at each main line makes all parts of the shop accessible by the track system.

Traveling-crane rails are framed below the roof trusses at a spacing to give crane spans of 23 ft., and intermediate spaces 12 ft. wide. The run of cranes in the first and fifth aisles is confined to those aisles, while the three aisles forming the plate-and-angle shop have runs continuous across all three, corresponding to the unity of work in these aisles. Sixty of the 23-ft. cranes are installed, 52 being of six tons capacity and eight of 10 tons. All are operated electrically and are controlled from the floor. They furnish a complete handling equipment for each machine or small group, as the case requires, thus preventing the delays that are likely to occur when cranes traveling longitudinally serve a number of operators.

At the receiving-yard end of the building are two 5-ton electric traveling cranes with a span of 43 ft., operating on a runway extending entirely across the shop, by means of which it is possible to transfer material crosswise without using floor trucks on the cross-track near the center of the building. As shearing and most of the detail work are performed before other fabrication, these two cranes distribute the steel to the different aisles after this preliminary work is completed.

Furnace and Forge Aisle—Designed for the fabrication of all furnaced and smith work, the first aisle has three channel and angle furnaces for material 40 ft. long and one for shapes 50 ft. long, all built out into the receiving yard. These furnaces are inclosed within brick walls and are protected by reinforced-concrete roof slabs.

Some of their auxiliary mechanical features, of very unusual type, accomplish marked saving in labor. The shapes to be bent enter the furnaces from the receiving-yard end over a roller table and are moved forward by a motor-driven frame. When the steel is heated, it is

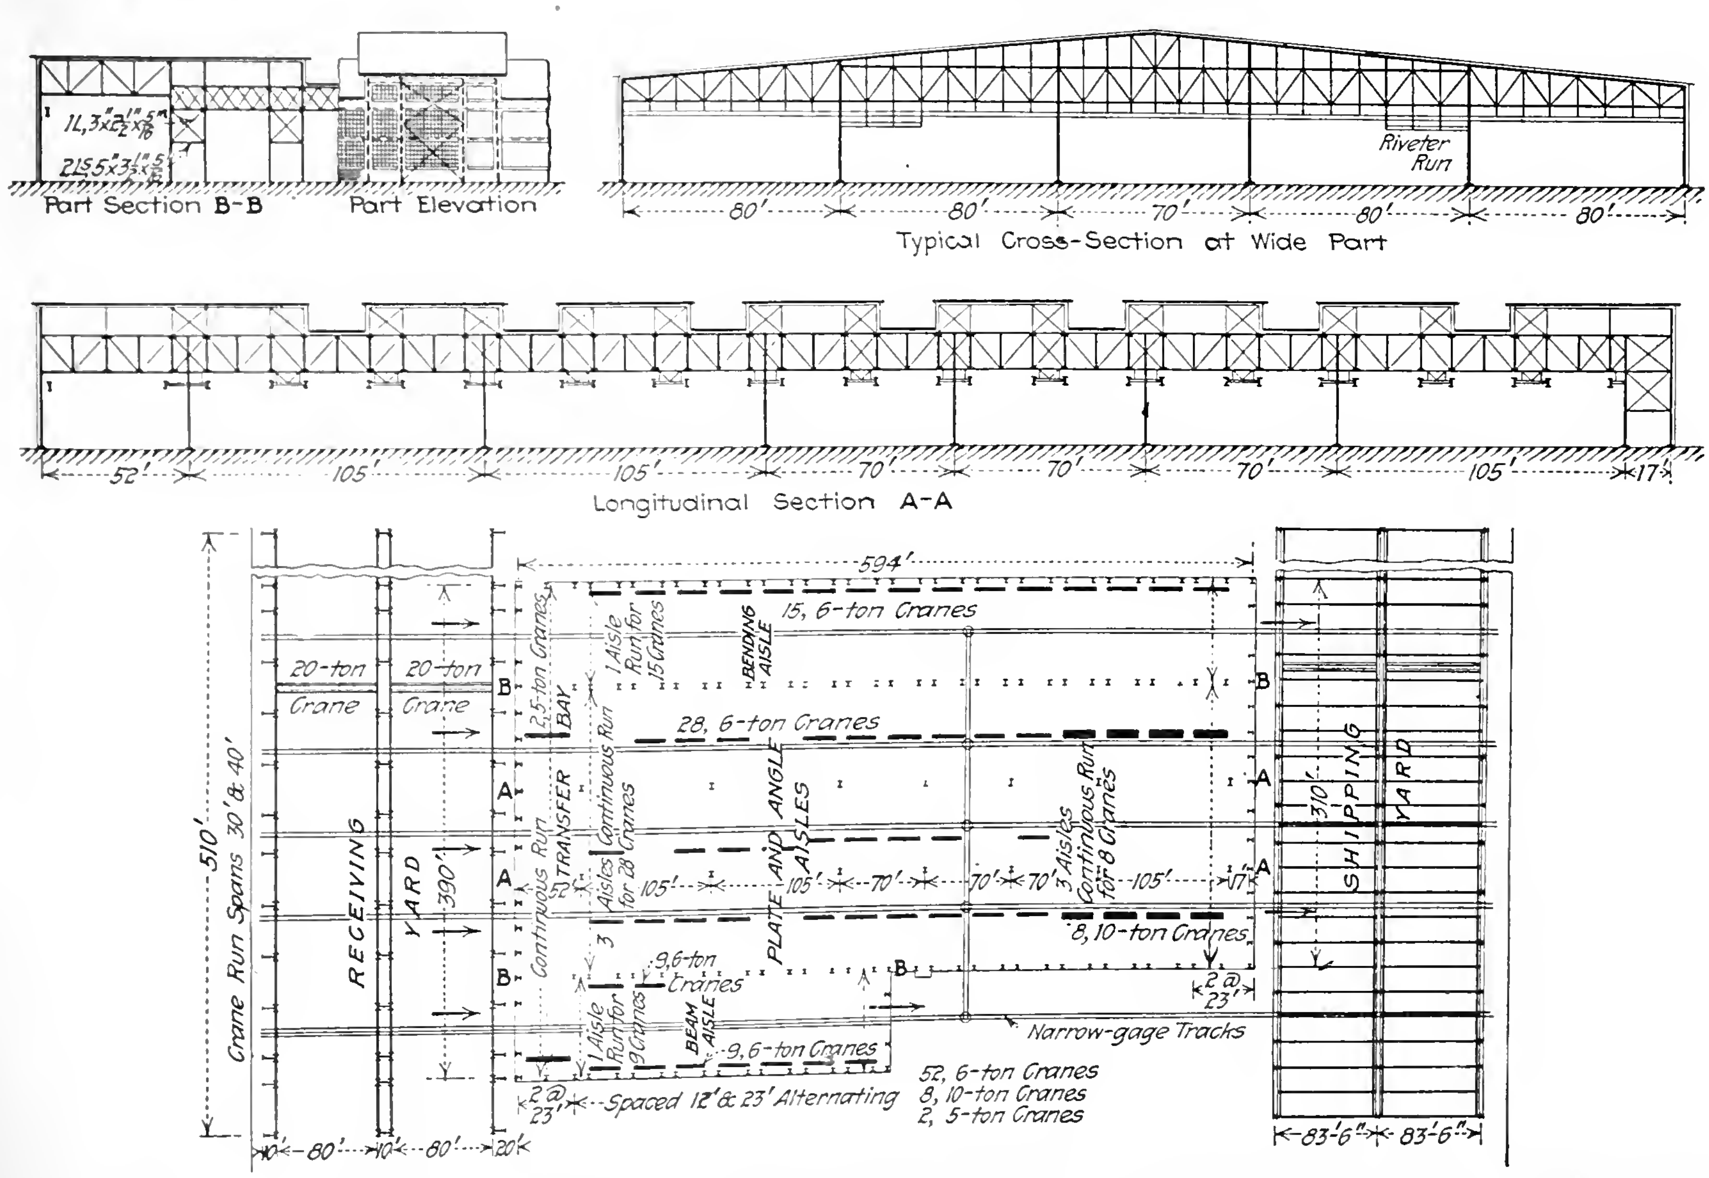

FIG. 2. SHIP-FABRICATING SHOP ARRANGED IN FIVE AISLES SERVED BY TRANSVERSE OVERHEAD CRANES AND LONGITUDINAL TRACKS; RECEIVING YARD AT LEFT, SHIPPING YARD AT RIGHT

pushed out of the other end of the furnace by the same power and then through a flaring or beveling machine, which, in the case of channels, flares both flanges at the same time. The shape is then on the bending floor and is pulled by electric winches around pins in the floor set to templet. This is all done in one heat.

The bending-slab area of the two sets of furnaces is 4200 sq.ft. One motor-driven beveling machine is provided for each pair of furnaces, each being mounted on a truck running on a narrow-gage track parallel to the front line of the furnaces, so that the machines can readily be placed in position where needed. Of the two machines, one is designed for angles and the other for channels.

The forge shop, following next after the bending floor, contains 12 forges and five blocks, for bending small angles and similar parts. There are also knuckling forges, hammers and a flanging press with furnaces adjacent, and a bulldozer and a gag press. Beyond these machines all material is worked cold. Layout skids are followed by four punches, two horizontal and two vertical.

At this point the cross-track enters the aisle. A 700-ton keel bender is located here for convenience; its base is set in a reinforced-concrete pit. An electric hoist on an overhead runway is provided for handling the steel fabricated by this machine.

Assembling Division—The remaining portion of the furnace and forge aisle forms the fitting and assembling shop. Two riveter runs with rivet-heating furnaces adjacent are required for the built-up sections; they are installed opposite each other along the sides of the aisle, in order to centralize the work. A second hydraulic gag-press, which is a duplicate of that near the forges, and two radial countersinking arms, complete the equipment. This division of the aisle, then, forms an independent shop for certain classifications of ship steel.

Fabricated material leaving the aisle is finally advanced by truck over a track scale at the entrance to the shipping yard and is ready for shipment.

All the hydraulic machines in the plant, except one, are located in the bending aisle. Tables are provided for the countersinking arms only. All other equipment is served by two-ton jib cranes with electric hoists. Similar hoists are provided for the riveter runs.

Plate-and-Angle Section—The second, third and fourth aisles may be considered the plate-and-angle shop, though it is subdivided into several separate units. In the second aisle narrow rectangular plates, sketch plates and angles (except the largest sizes) are fabricated. Further, this aisle, in conjunction with the first, builds the floors of the ship, as they consist of narrow vertical plates, angle frames and intercostals. This is all punched and riveted work which can be carried along uniformly and assembled without transfer to other parts of the shop.

For plate punching, one 12-in., three 48-in., and four 72-in. punches are provided in the second aisle, those with 48-in. throat being equipped with roller tables, and the large punches with tables manually operated in two directions. Two 48-in. plate shears, with roller tables, and a rotary shear were installed near the 72-in. punches for convenience in fabricating sketch plates and similar work. Opposite one of the 48-in. punches is a joggling press of 350 tons capacity, provided with electric hoist and runway, and designed also to cut manholes up to 18 x 30 in. at one stroke. These openings were formerly cut by flame in most shops, and this part of the floor fabrication was therefore performed with unnecessary delay and difficulty, on account of lack of better facilities.

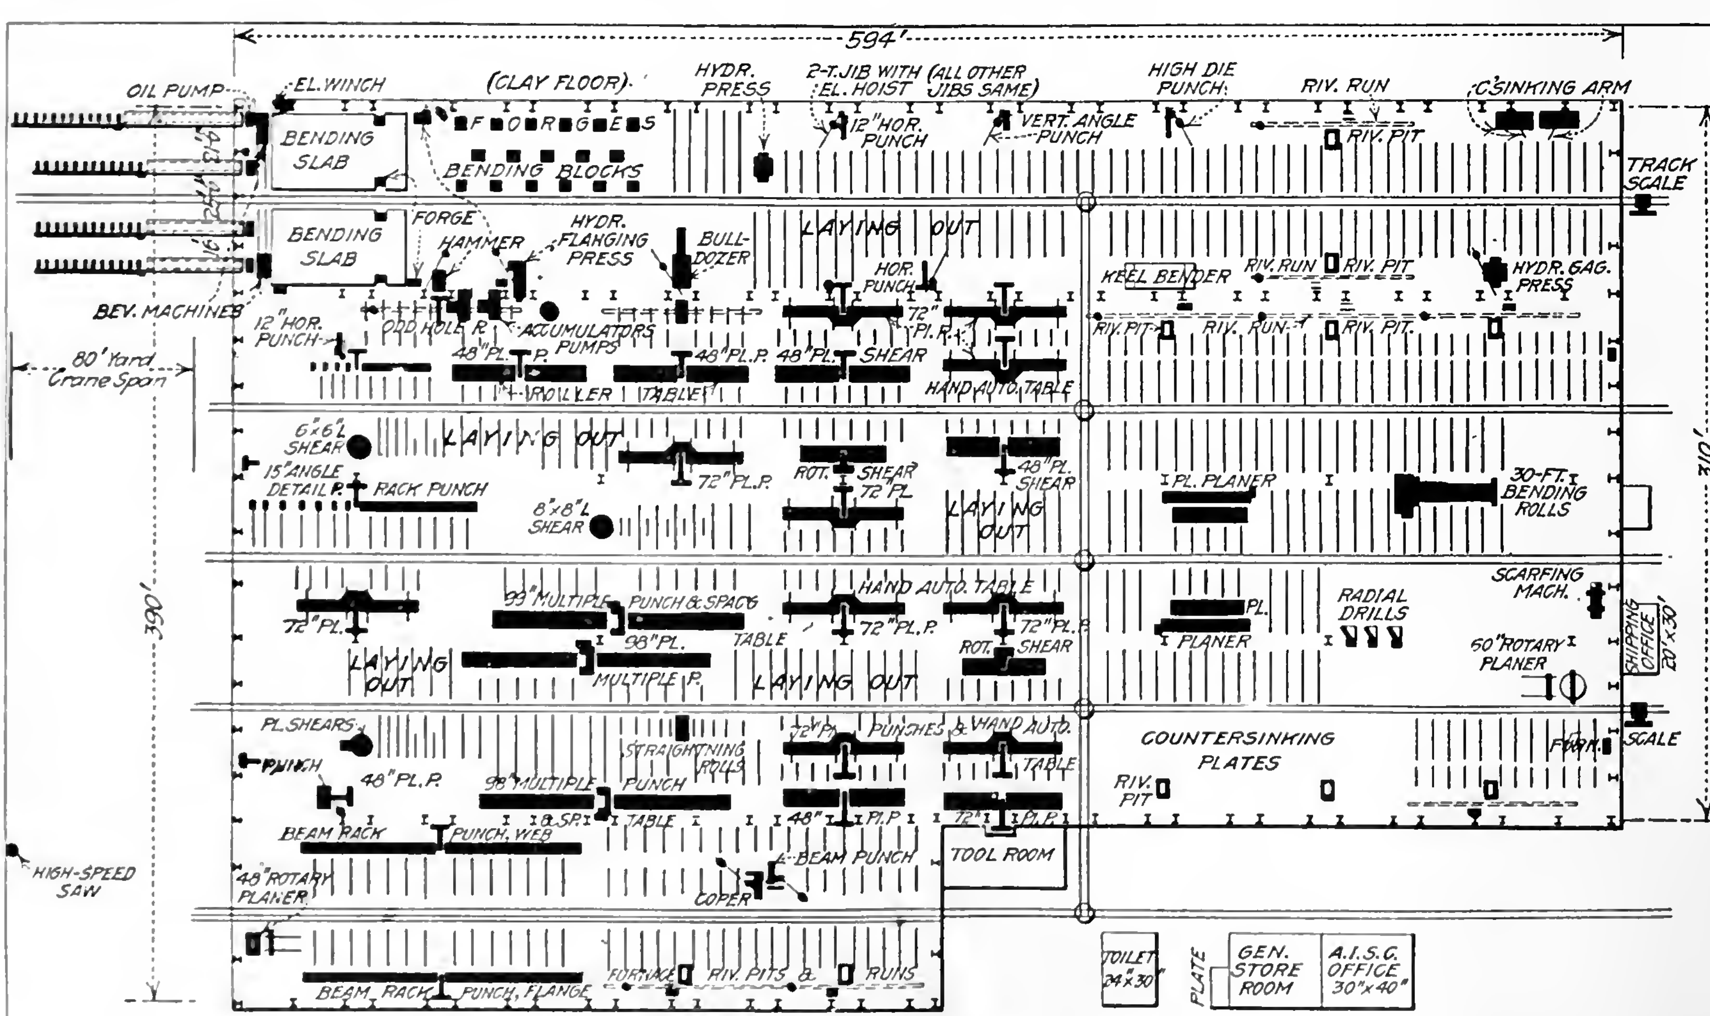

FIG. 3. ARRANGEMENT OF MACHINES; MATERIAL MOVES FROM LEFT TO RIGHT IN FABRICATING SHOP

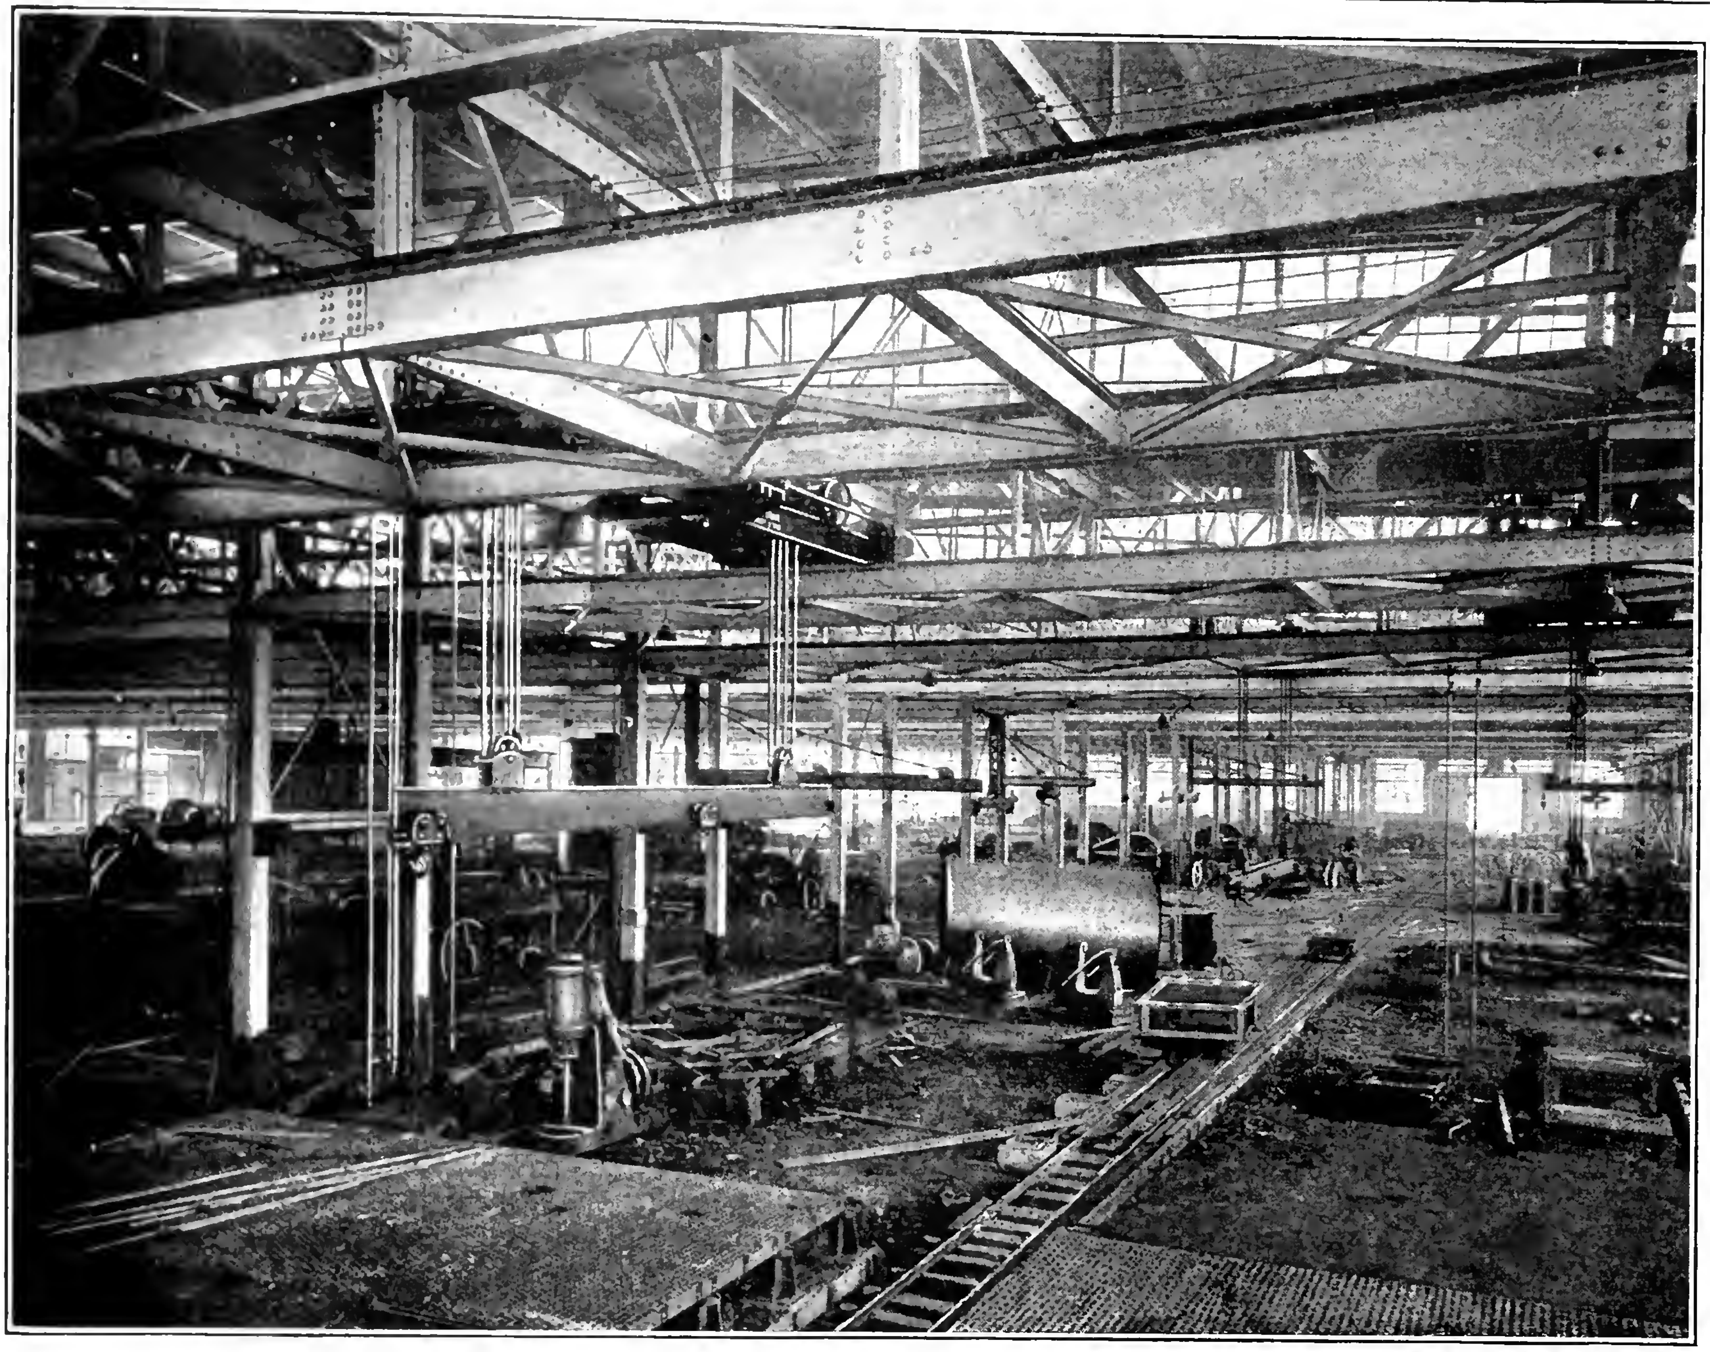

FIG. 4. BENDING AISLE OF POTTSTOWN SHOP IN DECEMBER, 1918, WHILE MACHINERY WAS BEING INSTALLED

The angle shop is not a separate division within the aisle, but the equipment is located at the beginning of the aisle for convenience. It consists of an angle shear on a rotary base, a two-angle rack punch with a spacing table, an odd-hole punch, and a 15-in. detail punch. The remainder of the aisle, which represents two-fifths of its area, is arranged for assembling the parts, and three riveter runs are provided for the purpose.

Multiple Punches for Large Plates—All large plate work, such as shell and deck plating, bulkheads and tank tops, and also large angles, will be fabricated in the third and fourth aisles. Since this plate work involves only planing, punching and countersinking, a large tonnage will be obtained from the three 98-in. multiple punches located near the receiving-yard end of the shop. These machines will punch 40 holes $\frac{15}{16}$ in. in diameter through $\frac{3}{4}$-in. metal and shear a plate 84 x $\frac{3}{4}$ in., all at one stroke. Two of the punches are equipped with end shears and side-trimming knives. Roller tables of original design are provided.

For plates which cannot be entirely punched in the multiples, and for other single punching, six 72-in. punches with manually operated tables, and one 48-in. punch with a roller table, follow the large machines. Irregular and curved cuts are made by a rotary shear after the plates are laid out. The detail work is done at the beginning of the aisle by a 25-in. and a heavy 48-in. punch. Special shearing is also done at this point, the plates being deposited over an inclined table. For straightening plates, a set of six rolls has been installed near the punches, with capacity to correct 1-in. plates at a speed of 35 ft. per minute.

After punching is completed, the plates are laid out and are advanced to the planers, located in the third aisle. Two of these machines are required to balance the plate capacity of the punches. They will plane the edges of plates 1 to $1\frac{1}{2}$ in. in thickness to a length of 30 ft. at one setting; the plates are clamped by a series of pneumatic jacks.

Molded plates will be passed through a set of 30-ft. bending rolls adjacent to the planers. A row of three radial drills for holes that cannot be punched, and also floor space for operating portable buggies carrying motor-driven countersinking drills, are provided near the end of the third aisle. Ten of these buggies, each operated by one man, are required for the plate shop.

Before passing over the scales, the plates from the third and fourth aisles are planed by a 60-in. rotary planer, and are also scarfed, where necessary, on a double-head machine. Three riveter runs at the end of the fourth aisle handle the work requiring shop riveting, which is fabricated on this side of the plate-and-angle shop.

The angle shop in these two aisles was placed at the receiving-yard end, adjacent to the second aisle, where it forms the part of the group handling the heavier

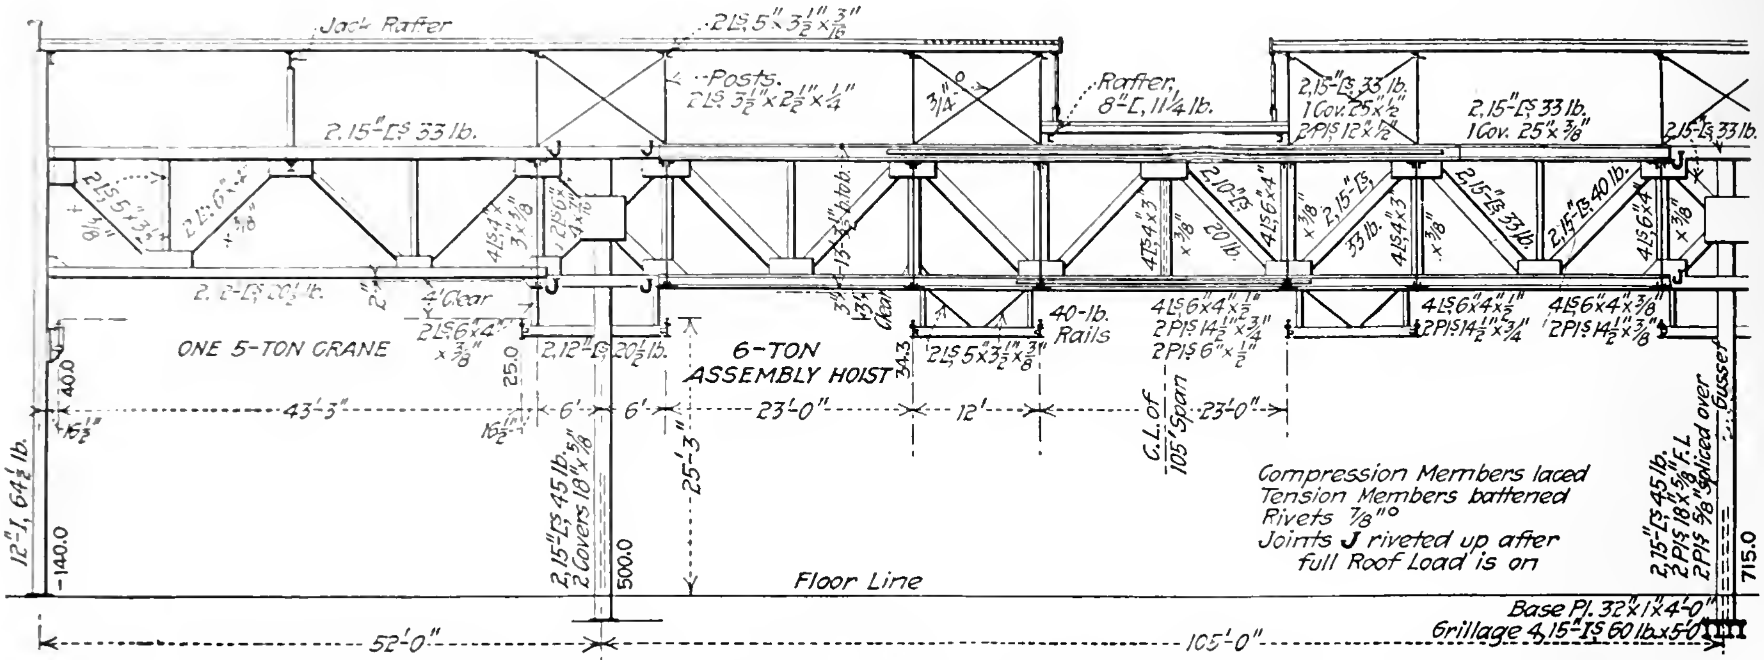

FIG. 5. PLATE-AND-ANGLE AISLES KEPT CLEAR BY WIDE SPACING OF COLUMNS AND SUPPORT OF ROOF BY LONGITUDINAL TRUSSES

material. A 15-in. detail punch, a 4-angle rack punch with a spacing table, and double shears on a turntable for angles up to 8 x 8 x 1¼-in., constitute the equipment.

Beam Shop—The fifth aisle, forming the beam shop, is only 303 ft. long, about half the length of the building. A high-speed friction saw, operated by a 45-hp. motor, is included in this equipment, although located not in the shop itself but just opposite its entrance, in the receiving yard. This saw is designed to cut continuously up to 24-in., 80-lb. beams, and equivalent channels, Z-bars and angles. One 48-in. rotary planer, with tracks and carriage, at the beginning of the aisle, is sufficient to meet the requirements.

On opposite sides of the track, near the entrance, are two beam punches, one for webs and the other for flanges, with die blocks of sufficient height to punch also 8 x 8-in. angles. Spacing tables are provided for these machines. A special beam punch and coping machine follow the punches, with capacity for all standard sections up to 24 in. and for Bethlehem sections up to 30 in. A 24-in. odd-hole beam punch adjacent to the coper completes the equipment in the aisle, except for the riveter runs, of which there are two. No tables are provided for the coper and adjoining punch, as the steel will be handled by jib cranes. This aisle contains the only standard-gage track entering the building; it is laid in conjunction with the industrial track.

Full Equipment of Skids—Throughout the entire building, skids built up of angles and channels form part of the equipment at each machine, wherever their use will facilitate the handling of the steel. Laying-out and assembly skids are 2 ft. high; those for partly fabricated material are 9 in. high; those for certain other machines are of heights required by the special conditions. At the plate-and-angle shears, skids with roller tops are used, and at the riveter runs the skids are movable. In the yards 10 x 10-in. oak skids with steel bar or rail wearing surface are provided.

The offices for the shipping-yard and receiving-yard clerks, and for the superintendent and the inspector, are built as lean-tos, as are also the tool room and electric repair shop. All other auxiliary buildings are detached. The electrical shop contains transformers which step the voltage (2300) down to 220, used for power throughout the shop, except for the cranes, which are operated by direct current of the same voltage. From the second floor of this lean-to a walkway extending through the roof trusses gives access to the cranes for repairs. The main shop is well lighted throughout, with 500-watt lamps in reflectors.

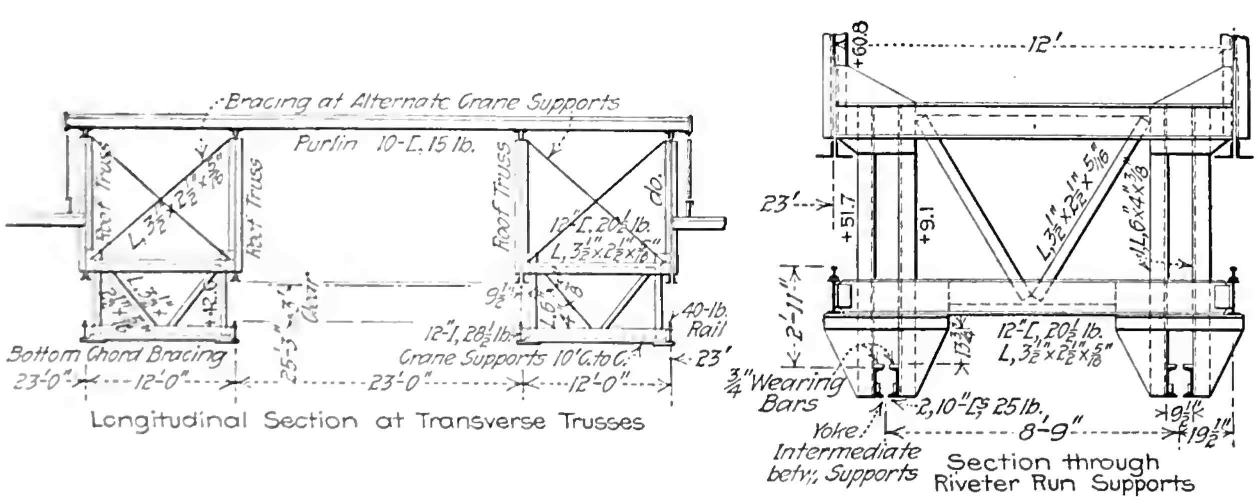

FIG. 6. TYPICAL CRANE-RUN SUPPORT DETAILS

A. McKinley of the McClintic-Marshall Construction Co. designed the Leetsdale and Pottstown plants. The buildings were erected by the Hughes-Foulkrod Co., under the supervision of C. H. Harlan and H. C. Walton, managers of construction at Leetsdale and Pottstown, respectively. J. W. Fenton, assistant authorized representative, was in charge of the work at Pottstown for the Emergency Fleet Corporation.

Head-Office Expense of Highway Department

The division of head-office expense in the New York State Highway Department for the year 1917 is shown in the annual report of H. Eltinge Breed, first deputy commissioner of highways, to be as follows: Checking of final estimates, 23.12 per cent; maps, 13.53 per cent; plans, 13.40 per cent; miscellaneous, 25.22 per cent; lettings, 9.76 per cent; repair work, 7.46 per cent; bulletin, 3.98 per cent; Federal aid, 3.53 per cent.

Preparing Six Hundred Acres of Land for Irrigation

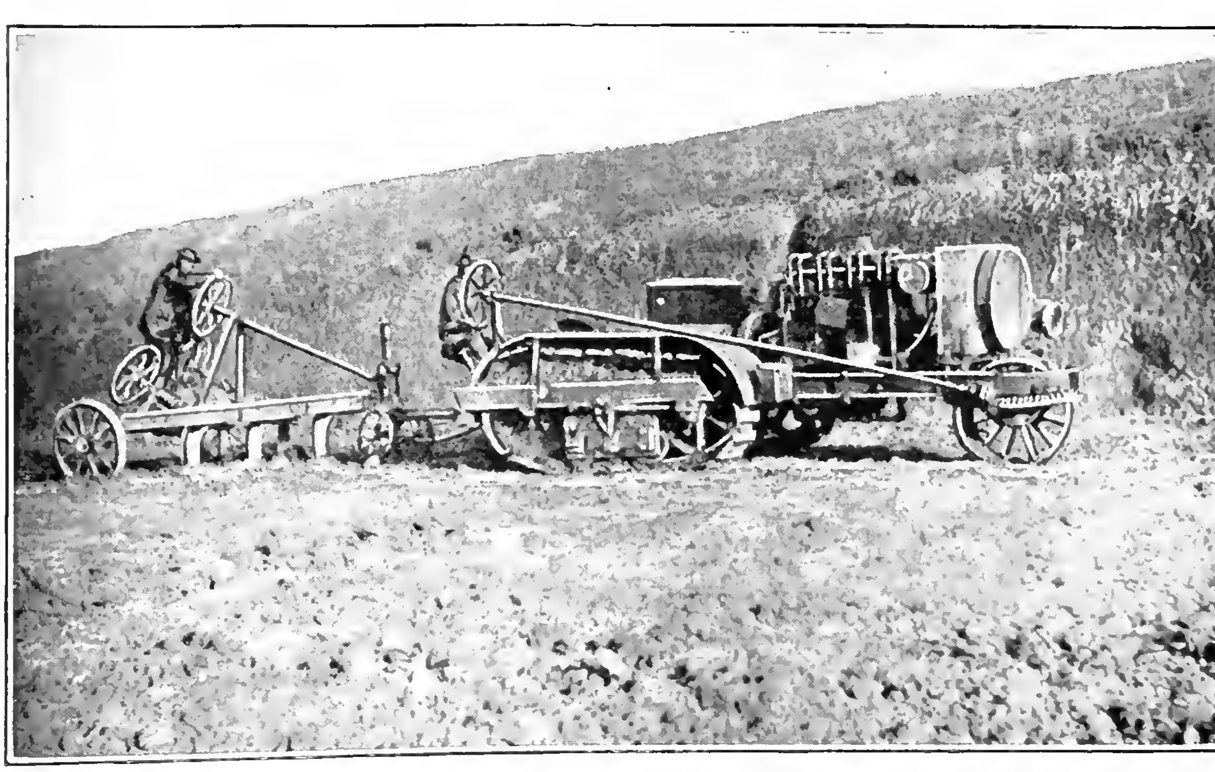
Soil Studies, Surveys, Supply and Drainage Ditches—Land Leveling and Ditch Construction Operations Described—Tractor Plows Run Day and Night—Ground Planes and Scarifiers Used

By F. W. Herron
Daly City, Cal

In preparing large tracts of land for irrigation, engineering methods are employed to an increasing extent. Especially is this true when modern farm tractors are used, as the large amount of capital invested in equipment of this kind and the high cost of operation render it essential that the work shall be carefully planned and economically executed. The following account of the preparation of a 600-acre tract with a construction outfit that included 35 scraper teams and five Holt caterpillar tractors describes briefly the engineering features of this kind of work, and gives a summary of costs.

The tract in question is the property of the Crocker-Huffman Land & Water Co., of Merced, in the San Joaquin Valley, California. For some time it has been the policy of this corporation to prepare and seed to alfalfa each year a part of its extensive land holdings included in the Merced irrigation system. The writer was in charge of field work for the company from August, 1915, to July, 1917, and during this two-year period supervised the preparation of about 2500 acres of land, including the tract described in this article. These notes on the work were prepared directly after its completion, but for reasons beyond the control of the writer could not be published then.

The soil on this tract is classed by the Bureau of Soils, United States Department of Agriculture, as Madera clay, and is described as follows: "The Madera clay is a dark brown or reddish brown clay or silty clay varying considerably in texture within short distances. It is compact and very difficult to handle, especially when not worked under proper moisture conditions. When drainage is established, the soil is well adapted to irrigation." In reading this article, and especially considering the cost data, it should be borne in mind that this work was done under very unfavorable moisture conditions, when the ground was too dry and hard to be handled with ordinary horse-drawn farming implements. Before designing the irrigation and drainage system, the writer made a contour map of the tract, to a scale of 400 ft. per inch, and a contour interval of 0.5 ft. Field work was done with transit and stadia. On the finished map a rough paper location was made of all laterals and field ditches and also of all main drainage ditches. Distances and bearings were scaled from the map, and the ditches located in the field with transit and stadia, using compass bearings.



SCARIFIERS DRAWN BY 30-HORSEPOWER TRACTORS LOOSEN DIRT FOR DITCHES AND CUT DOWN KNOLLS

All laterals and field ditches were 8 ft. wide on the bottom, with side slopes of 2: 1, a total depth of 4 ft., and with banks 3 ft. wide on top. The usual grade was 1 ft. per 1000 ft. These ditches were so located and constructed that water could be held in them 1 ft. above the highest ground to be irrigated, but in no case was the high-water mark allowed to approach closer than 1 ft. to the top of the ditch bank. Ease of construction and maintenance and an ample water-supply were assured by the adoption of the 8-ft. bottom width for all ditches, while the substantial banks and generous freeboard allowance insured against expensive breakages and seepage losses. Drain ditches were also 8 ft. wide on the bottom, and about 2 ft. deep, and were located as far as possible on natural drainage lines. They were intended, of course, to provide surface drainage only.

As the ground surface was rough and broken, with numerous large knolls and depressions, it was necessary in laying out the tract to adopt the method known as contour checking. In this method low levees are built on contour lines, and the areas between levees are irrigated by flooding. The contour interval used in this case varied from 5 to 0.3 ft., the latter being employed wherever possible. The check levees were 6 ft. wide on the bottom, and from 12 to 16 in. high. Levee lines were located on the ground by a level party, which set stakes from 50 to 100 ft. apart, marking them with the contour elevation. In order to render these stakes plainly visible, the writer adopted the cheap and very

TABLE I. COST OF PREPARING 600-ACRE TRACT FOR IRRIGATION

	Per Acre	
Engineering and Superintendence:		
Surveying	$1 37	
Superintendence and overhead	1.90	$3.27
Team work:		
Irrigation ditches	10.73	
Drainage ditches	5 68	
Checking and leveling	5 19	21.60

Structures:		
Canal structures	4 20	
Service structures	11.61	15.81
Total cost per acre		$59 03

Total length of irrigation ditches, 33,200 ft. Total yardage moved, 44,513 cu.yd., or 1.34 cu.yd. per linear foot of ditch. Cost per cubic yard, $0.172.

effective expedient of dipping the tops in whitewash. Great care was taken in locating the levees to avoid all sharp bends and loops and to make the total amount of earthwork a minimum, at the same time securing a check that could be irrigated quickly and evenly. After the lines were located they were marked by a single plow furrow, and the levees were constructed by a small gang of scraper men with special experience in that kind of work.

In starting construction work, a block containing about 100 acres was laid off at one end of the tract and plowed by the tractors. One 75- and two 60-hp. tractors were employed on the plowing, each drawing two six-gang disk plows. The ground was so hard that the plows were frequently broken, and in the case of the 60-hp. tractors it proved necessary to remove two disks from each rear gang. As soon as this block was plowed, work was started on another, about the same size, and immediately adjacent to the first, plowing with night shifts only. Day crews were started on the first block rough leveling with ground planes. Ditches were also staked out on this block, and construction work was started on them with teams and fresnos. As soon as the ground was approximately level and the ditches were completed, the levees were staked out and built, and the ground inside the checks was finally leveled by the ground planes. Work proceeded in this way from one end of the tract to the other, the different gangs being so proportioned that all main ditches were built well in advance of the levee building and finish leveling.

As soon as the checks were completed, stakes were set to mark the location of all water gates and boxes and a gang of men was put to work making the excavations for them. Double-wing wooden gates, with a 6-ft. opening, were placed in the canal banks at all points at which water was to be diverted to the checks, and also in the levees wherever water was to be turned from one check to the other. Smaller single-wing boxes were placed in the levees at points where the water from a check was discharged into a drainage ditch. All these service structures were built at the ranch headquarters, three miles away, and hauled to the work by a three-ton motor truck, which distributed them in convenient piles along the road bordering the tract. From these piles the gates were loaded on wagons and hauled to their places in the field. Over 200,000 ft. bm. of cedar lumber, costing about $30 per 1000 in place, was used in making these gates and boxes.

Some special implements used on this work were the ground planes and the scarifier shown by the two views. These ground planes were invented by Henry A. Lage, general superintendent of the Crocker-Huffman Co., and were built on the ranch under his direction. They are easily handled, move dirt at a low cost, and very thoroughly pulverize the most refractory soil during the process of leveling. A 12-ft. plane, drawn by a 60-hp. tractor, will average about 2 yd. of dirt at a load, and in ordinary leveling will handle from 200 to 300 yd. per day. The depth of the cut or fill is easily regulated, and excellent leveling can be done by the ordinary unskilled laborer, after a few days' practice.

TABLE III. PERFORMANCE RECORD OF 45-HORSEPOWER TRACTOR NO. 20080

Item	Hours	Minutes	Per Cent. of Total Time
Starting delay	20	50	4.84
Engine trouble	8	20	1.94
Repairing track	5	30	1.28
Repairing cooling system	12	45	2.96
Repairing implements	5	35	1.29
Filling and greasing	23	00	5.35
Traveling to and from service station	18	45	4.36
Rain	8	00	1.86
Lost time	102	45	23.88
Working time	327	15	76.12
Total time, 43—10-hr. days	430	00	100.00

The scarifier was used in loosening dirt in the ditches and in cutting down some of the large knolls, as the very hard soil could not be plowed successfully by the teams. This scarifier was drawn by a 30-hp. tractor and loosened about 1000 cu.yd. of dirt per day, breaking it up so that it was easily handled by the fresnos. In the illustration the scarifier is shown breaking up hardpan in a large canal constructed in another part of the county.

Itemized costs of the work are given in Table I. Table II shows the daily cost of operation of a 60-hp. tractor and Table III is a performance record of a 45-hp. tractor which was used in plowing, harrowing, and scarifying in the finished checks, to prepare them for seeding. These performance records were kept for each machine and served a double purpose. Not only did they reveal errors in operation and deficiencies in equipment but they also fostered a healthy spirit of rivalry, between individual tractor drivers, that resulted in decidedly increasing the amount of work performed per tractor per day. All data shown in these tables were abstracted from the complete records kept by the company, and are accurate and reliable.

In the past the irrigation engineer has considered his

TABLE II. DETAILED COSTS OF OPERATING 60-HORSEPOWER TRACTOR NO. 2008

Item	Cost per Day
Interest and depreciation	$4 56
Wages of tractor crew	4 80
Board of tractor crew	1.68
Teams	.50

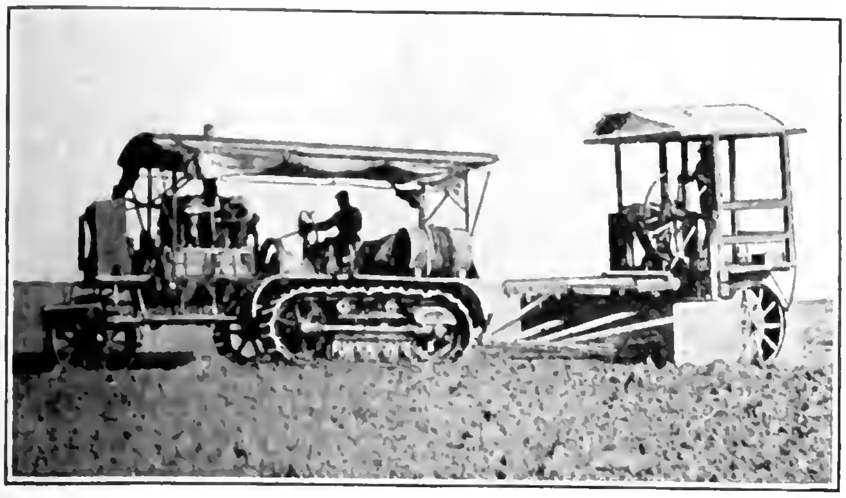
Cup grease, 2.5 lb	13
Repairs	4 08
Miscellaneous labor	2.43
Miscellaneous supplies	.78
Implements (repairs, interest and depreciation)	2.71
Superintendence and general overhead	2 67
Total daily cost	$27.71
Total daily cost:	
Tractor No. 2116, 75 hp	30 20
Tractor No. 2003, 60 hp	25.70
Tractor No. 20080, 45 hp	17.25

work completed when he has brought the water to the outskirts of the irrigable land. The equally important and rather more difficult task of preparation for the efficient and economical application of the water to the soil has been left largely to the farmer. The partial or complete failure of most of our irrigation projects will testify to the fact that this method of procedure



GROUND PLANES DRAWN BY 60-HORSEPOWER TRACTORS LEVEL LAND AND PULVERIZE SOIL FOR IRRIGATION

has not been an unqualified success. Since increased crop production has become and will doubtless remain a matter of great national importance, the writer believes that the engineering profession can well afford to devote some of its attention to the problem of the economical preparation of land for irrigation.

American Engineer at Burma Camp Fights Epidemics

Detention Camp on Railroad Effective, but Coolies Bring in Cholera Through Jungle—No Uncooked Food Permitted

By Harry N. Jenks

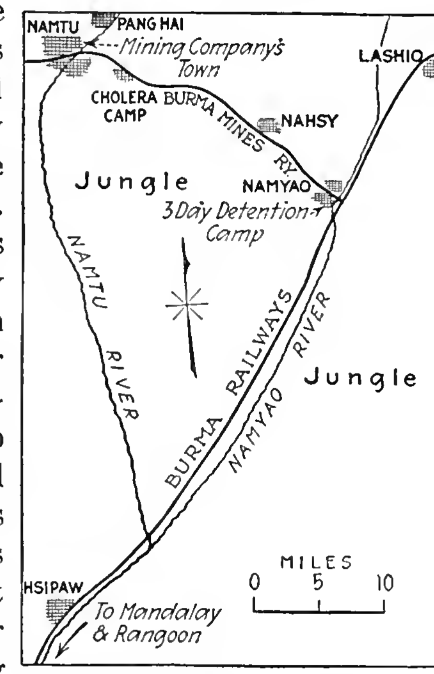
Sanitary Engineer, Burma Mines, Limited, Namtu, Burma

Combatting three highly contagious deadly diseases within six months, two of them simultaneously, in the experience of the author of this article, a young sanitary engineer of Berkeley, Cal., who has been with a British mining company at Namtu, Burma, India, for the past two years. As an instance of where and into what the coming international trade will carry pioneering American engineers, these notes and also Mr. Jenks' longer article on sanitation at the Namtu mining camp, printed in "Engineering News-Record" of Jan. 23, p. 172, are timely and informing.—Editor.

Things may happen slowly in Burma, but when they do happen they take a long time to stop. For the first time in the camp's history, we had bubonic plague last spring; and it is only now (Oct. 18, 1918) that we are nearing the end of a four months' fight against cholera, a fight that was made all the more difficult by the simultaneous occurrence of a severe epidemic of influenza. From the standpoint of training in public health work, this year has furnished me with exceptionally good experience, but the number of coolies that have been claimed by the epidemics, and those that have disappeared into the jungle to escape infection, have left us with barely enough labor to "carry on."

This has been a particularly untoward year all over India, as regards the prevalence of sickness. Unseasonable weather created conditions that seemed to favor the spread of both influenza and cholera. Earlier in the year the unusual conditions of temperature and moisture were, presumably, largely responsible for the appearance of plague, which in the first instance came probably from some previously infected place, such as Mandalay. Neither the plague nor the cholera was in true epidemic form, occurring as each disease did in sporadic cases, mainly with no apparent causal connection. If, however, there ever was an epidemic anywhere, the influenza that struck us takes highest honors. It started about last June in Bombay, traveled all over India, came up through Burma from Rangoon, and carried away with terminal pneumonia some 200 known cases among the natives in Namtu.

Our cholera troubles started last June, when the disease broke out in Hsipaw and spread through the jungle, paralleling the Burma Rys., as far as Lashio. The sketch shows the position of these towns in relation to Namtu and the company's railway that connects with the Burma Rys. at Namyao. Precautionary measures were taken immediately to prevent the infection from traveling up our line to Namtu. We established a detention camp at Namyao, where all third-class passengers from the Hsipaw side as far as Maymyo were kept under observation for three days before being allowed to proceed on our railway. All foodstuffs from infected areas were destroyed. No food that could be eaten uncooked was permitted to be kept for sale in the local bazaars. Guards were placed on roads and trails through the jungle to intercept all persons going from infected areas toward Namtu.



THREE-DAY DETENTION CAMP AT NAMYAO KEPT CHOLERA FROM NAMTU FIVE WEEKS

In this and other ways we kept the infection at a distance for about five weeks, when a case suddenly developed in Namtu, and within a few days sporadic cases were reported all along the line to Namyao. Pretty nearly everybody was then taken off his regular job and detailed to help the medical and sanitary staff to cope with the situation. In this work we received the assistance of Government medical officers, who spotted cases and administered treatment. We built a big cholera camp at Hsaikhao to receive contacts and to care for the cases that developed among them, and for such cases as could be sent to the camp.

In Namtu we placed a European guard, working in eight-hour shifts, over our water-supplies. We discontinued the fresh milk supply, and for a while subsisted mainly on potatoes and onions for vegetables. A cordon of men was flung around the European side of the camp, and a guard was stationed at the bridge across the Namtu, in order to prevent any coolies from

the jungle coming into camp. This step was necessary because of the fact that the coolies had the dangerous habit of straggling along the open road or through the jungle from village to village when in the initial vomiting and purging stage of the attack.

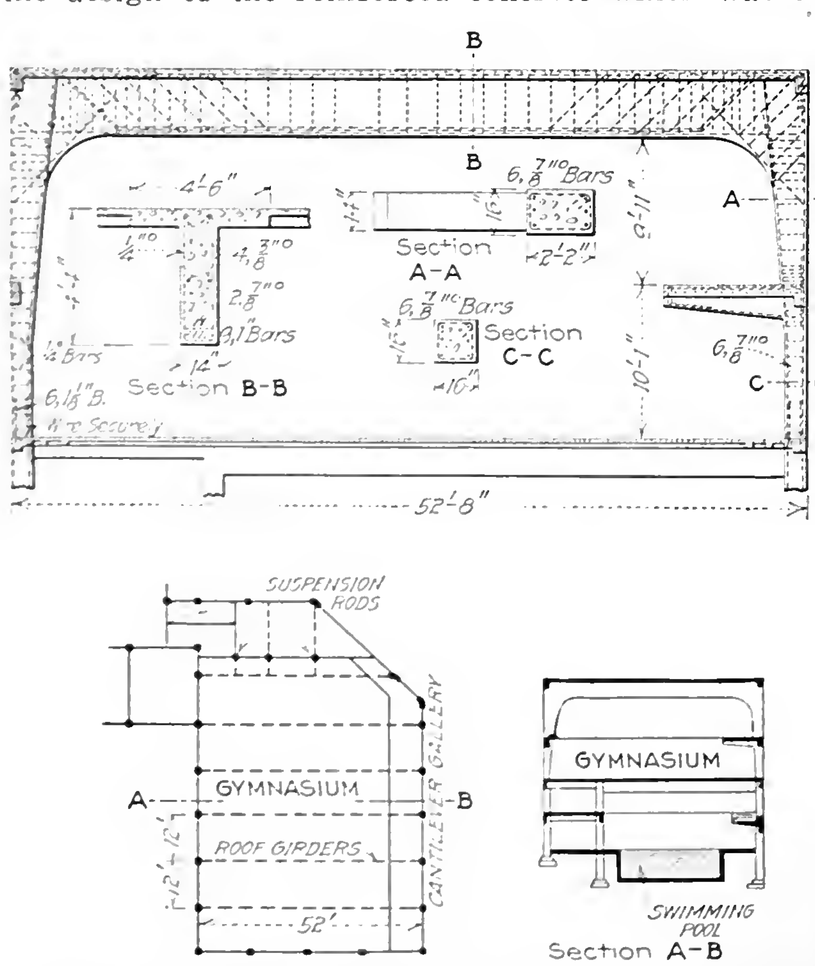
Within a short time Namtu itself was freed from infection, but up to Oct. 18 residual cholera has persisted in the jungle stations and villages. About four weeks ago I was detailed to take charge of the anti-cholera work along the railway, with headquarters at Nahsy, in order to attack the last footholds of the infection. After three weeks' work, the chief features of which were the continual inspection of all dwellings, the spotting of cases of sickness and provision for their treatment, and the disposal by incineration of those cases that terminated fatally, we have apparently attained our object; although even after the required 21 days' time has elapsed since the last case one cannot be certain that a sporadic case may not appear suddenly.

Long Girders and High Columns Designed as Rigid Frame

Gymnasium Requiring 52-Foot Span and 20-Foot Clearance in Height Carried as Third Story of Building

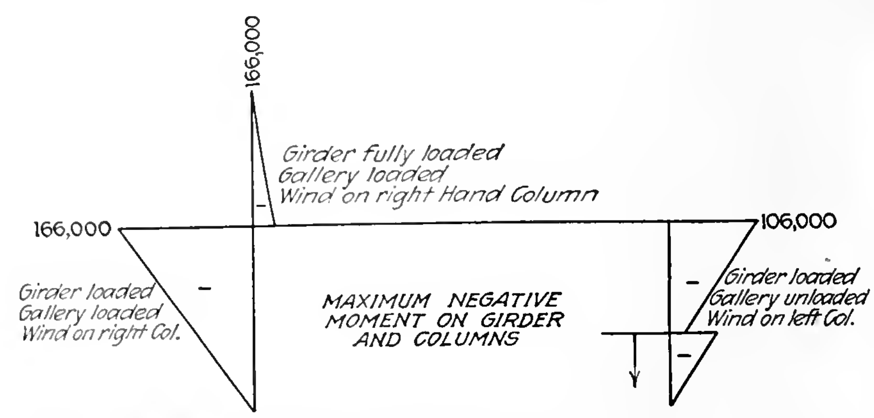
By A. E. Wynn
Truscon Steel Co., Syracuse, N. Y.

Architectural requirements in the layout of the Y. W. C. A. building, at Syracuse, N. Y., necessitated the use of some rather unusual details in the design of the reinforced concrete which was used throughout the building. In the gymnasium, a wing of the main building, a rigid frame analysis was followed for the 52-ft. roof beams and attached columns.



ROOF OVER GYMNASIUM OF REINFORCED CONCRETE, DESIGNED AS RIGID FRAME

The lower portion of this section of the building is excavated for a swimming pool 60 ft. by 25 ft. in plan and sloping in depth from 4 to 8 ft. The sides are 10-in. concrete walls reinforced for both earth and water pressure. Above the tank, and on all sides, is a gallery. Along two sides this consists of a slab, varying from 4 to 7½ in., thick cantilevered out 7 ft. from the wall lintels, and on the other two sides it is carried on beams and columns. Above the swimming pool is the gymnasium floor. This is carried over the pool by beams of 38 ft. span, 14 in. wide and 30 in. deep,



MAXIMUM NEGATIVE MOMENTS FOR EACH COLUMN AND GIRDER

Showing the column not carrying the gallery is under larger bending moment

with a floor slab of 4-in. terra cotta tile and 2-in. concrete.

The gymnasium itself had to be free of columns, so in order to frame the roof it was necessary to span 52 ft. from wall to wall at a height of 24 ft. above the floor. Long girders of this type are usually designed as simple beams freely supported at the ends, and the columns simply to take the total loads and then increase to a section conforming to some empirical rule, such as making the depth a certain fraction of the span and adding so much steel to the outside face. This method generally gives sections which are too large, and there is usually doubt as to what stresses exist in the columns. In this particular case the structure was designed as a rigid frame, the girder being considered monolithic with the columns. As it was to be used for sport, the roof slab was designed for a live-load of 100 lb. per square foot, and the columns and girders for 60 lb. per square foot. Maximum fiber stress in the girder was 650 lb. and in the column 700 lb. per square inch.

The design of the frames is shown in the accompanying detailed drawings. The columns are 12 ft. apart and in section are 16 in. wide and 26 in. deep at the top, and 16 in. wide by 16 in. deep at the bottom. They are reinforced symmetrically, the columns carrying the gallery with six ⅞-in. square bars, and the opposite ones with six 1⅛-in. square bars. The girders are 14 in. wide by 52 in. deep, the roof slab forming a T 54 in. wide, and they are reinforced with nine 1-in. and two ⅞-in. square bars. Some of the outside bars in the columns are bent over into the top of the girder, and some of the bars in the girder are bent well down into the columns, thoroughly bonding the girder and columns. At the junction of the columns and girder are curved brackets, which add greatly to the appearance of the structure and provide greater depth to the columns and girder at points of maximum negative moment.

The method used in designing these frames was as follows:

Any load acting upon the frame will cause the girder to take a certain slope at its junction with the columns. This slope can be calculated for any condition of loading and is dependent not only upon the loading but upon the relative stiffness of the girder and columns and the amount of fixation at the base of the columns. Knowing the angle of slope, the moment at the junction of column and girder required to produce this slope can be found. By equating the moments of the external forces on one side to this moment, the thrust at the base of the column is obtained. The moment at any point in the frame can then be easily found, and then the stresses.

Taking the simplest case of the girder uniformly loaded and using the following symbols:

l = span of girder columns c. to c.;
h = height of columns;
w = uniform load per foot;
L = slope of girder at junction to column;
E = modulus of elasticity;
I_B = moment of inertia of girder;
I_C = moment of inertia of column;

then

I_B/l is a measure of stiffness of girder

and

I_c/h is a measure of stiffness of column.
K = constant depending on amount of fixation at base of column = 3 if base is considered free.

Then for a beam uniformly loaded and considered as monolithic with the columns the slope L is given by

$$L = -\frac{wl^2}{12}\left(\frac{1}{\frac{3I_c}{h}+\frac{2I_B}{l}}\right)\frac{1}{E}$$

and the moment required to produce this slope is given by

$$M = K\frac{I_c}{h}EL$$

$$M = \frac{3I_c}{h}\left(-\frac{wl^2}{12}\times\frac{1}{\frac{3I_c}{h}+\frac{2I_B}{l}}\right)$$

$$= -\frac{wl^2}{12}\left(\frac{\frac{3I_c}{h}}{\frac{3I_c}{h}+\frac{2I_B}{l}}\right)$$

and if H = horizontal thrust, $H = M/h$. In a similar manner the thrust for other conditions of loading are found.

The different steps in design are as follows:

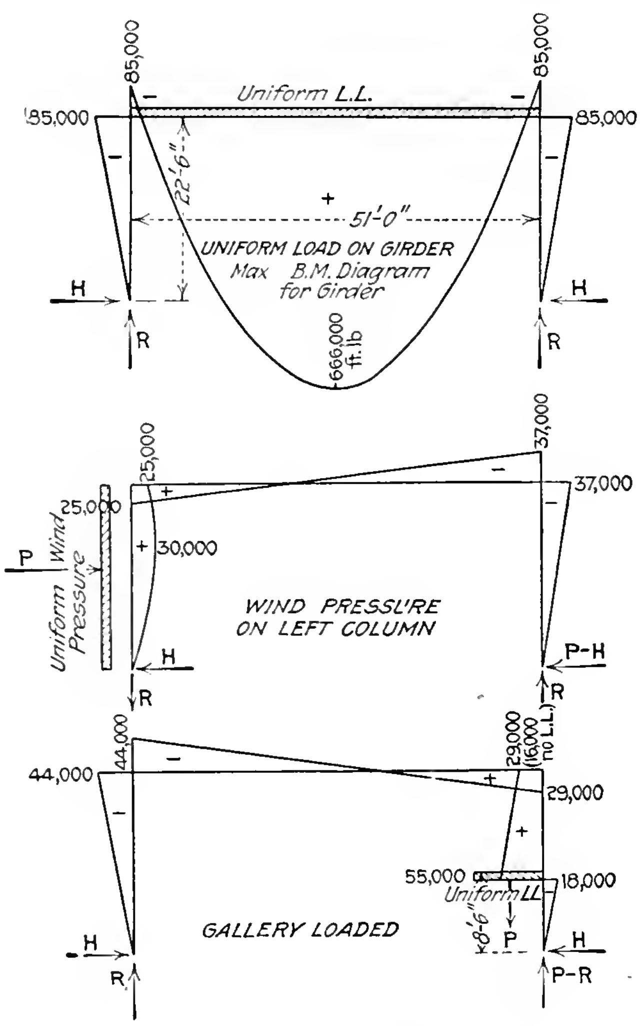
1. Design the girder with full live load for a bending moment of $wl^2/12$ at the center and $wl^2/24$ at the supports to obtain the approximate size, area of steel and width of T. Assume a column section, placing the steel symmetrically.

2. Calculate the moments of inertia of the girder and column.

3. Take the different conditions of loading, such as girder loaded and unloaded, gallery loaded and unloaded, and wind pressure on either side, and for each condition calculate the horizontal thrust H and vertical reaction R at the base of the columns, assuming that they are free at these points, as this condition gives the maximum moments in the columns.

4. Knowing these thrusts and reactions, the bending moment at any point in the frame can be found by taking moments about that point. Draw the moment diagram for each force acting upon the frame.

5. It will be seen from these, as shown in the accompanying diagrams drawn, for this particular case, which combination of loadings will give the maximum positive



BENDING MOMENT DIAGRAMS SHOWING BENDING ACTION OF LOADS ON GIRDERS FOR THREE DIFFERENT CONDITIONS OF LOADING

and negative moment in the girder and columns. Draw a final moment diagram giving these worst conditions combined.

6. Check the maximum moments found for the girder with those originally assumed.

7. Combine the maximum moment in the columns with the corresponding vertical reactions, and hence find the fiber stress for a column under bending and axial thrust.

8. If the moments in the girder differ materially from those assumed, and if the stress in the columns is higher or much lower than the allowable stress, it will be necessary to change the sections or steel areas or both, and as this will change the respective moments of inertia, the calculations will have to be repeated. Experience tells the sections to assume, and it is not often necessary to make more than two sets of calculations.

9. The outward thrust at the base of the columns must be taken care of by tie rods or if, as in this case, they are connected by beams, by the tension steel in the beams. It is not really necessary to draw the bending-moment diagrams, as an examination of the direction and magnitude of the thrusts will show which

are the worst conditions. Even if, as in this case, the columns are continuations of columns carrying the floors below, they cannot be considered as fixed at their base, but if any doubt exists as to the amount of fixation the calculations can be repeated for a frame with fixed ends and the stresses found at the foot of the columns. A much higher fiber stress can be assumed as safe, as absolute fixation hardly ever occurs.

Referring to the accompanying moment diagrams, it will be seen that the maximum positive moment occurs in the girder when the roof is fully loaded, the gallery is unloaded and there is no wind pressure. The column not carrying the gallery has maximum moment when the girder and gallery are fully loaded and with wind pressure on the opposite column. These conditions also give the maximum negative moment in the girder. The worst condition for the column carrying the gallery is when the girder is loaded, the gallery is unloaded and there is wind pressure on the opposite column. The roof load brings tension on the outside face of the columns and is a maximum at the top. Wind pressure brings tension upon the inside face of the column it is acting upon and upon the outside face of the opposite column, thus decreasing and increasing, respectively, the tension at the top of the columns.

When the gallery is loaded it brings tension on the inside face of the column above the gallery and on the outside face of the opposite column, having an effect similar to that of wind pressure.

The maximum fiber stress in the girder was 650 lb. per square inch and in the columns for worst conditions 700 lb. per square inch. The architects for the building were Taylor and Bonta, of Syracuse and the general contractors were Dawson Bros., of Syracuse.

Mechanical Devices Help Overcome Engineer Shortage

Combined with Tables and Standard Formulas, They Work Out Well in South Carolina Highway Department

By R. A. Brown

Assistant Engineer, South Carolina State Highway Department, Columbia, S. C.

WITH so many draftsmen and computers called into military service, it was a problem to utilize the less experienced men and get out presentable plans in a reasonable length of time. The State Highway Department of South Carolina lost 27 men to military service during the past 15 months. To utilize new recruits and some of the field men on plans and computations mechanical devices have been adopted, as it is easier for the average boy under 18 years of age to learn the use of a mechanical device than to perform intricate or even fairly easy computations.

A calculating machine is used by the department for most of the larger computations. Much of this work is done by a young woman who had no previous experience in engineering computations. To aid her in computing grades on vertical curves, the formula and a typical example worked out in detail were written out and pasted alongside the keyboard. The formula used is that for the approximate parabola: Middle ordinate, $M = \frac{1}{8}(G_2 - G_1)L$, where G_1 is the grade of the back tangent with proper sign, G_2 is the grade of the forward tangent with proper sign and L is the length of curve in stations. A plus result indicates that the ordinate is to be added to the elevation on tangent.

To enable the computers to find from the middle ordinate the ordinates at other points on the curve, the table herewith was computed for the curves usually used by this department. Having the middle ordinate, multiply it by the factor opposite the given distance and under the length of curve being used, to get the ordinate at any given distance from either end of the curve.

Since the grades can be added, the result multiplied

VERTICAL CURVE TABLES

Factors by which the middle ordinate must be multiplied to obtain ordinate at a given distance from point of curve. Example: On a 200-ft. curve, the ordinate at a distance of 27 ft. is 0.073 × middle ordinate.

Dist. Along Curve	200-Ft. Curve Factor	250-Ft. Curve Factor	300-Ft. Curve Factor	Dist. Along Curve	200-Ft. Curve Factor	250-Ft. Curve Factor	300-Ft. Curve Factor

50	0.250	0.160	0.111	100	1.000	0.640	0.444

by the length of curve, divided by 8, and the quotient multiplied by the factor taken from the table without clearing the calculating machine, the operation of figuring ordinates is accomplished very quickly. To find ordinates for 400-, 500- and 600-ft. curves, take one-fourth the ordinates given under 200-, 250- and 300-ft. curves, respectively, for the same distance.

It might be added that the calculating machine is used also for finding elevations of grade on tangents, as well as on vertical curves. Starting from a given elevation on the grade tangent, the rate of grade is added or subtracted successively for each 100-ft. station. For fractional stations the rate is quickly multiplied on the machine by the fractional station, and applied.

Letters to the Editor

Comment on Matters of Interest to Engineers and Contractors Will Be Welcome

Properly Allocating the Cost of Highway Transportation

Sir—The letter by W. Earl Weller, city engineer of Binghamton, N. Y., in *Engineering News-Record* of Jan. 9, 1919, p. 107, brings up a question that must be settled sooner or later, and to which I believe consideration should be given now—that is, the question of properly allocating to the cost of goods transported over the highways by motor trucks their fair share of the cost of building and maintaining those highways.

Though I do not agree with Mr. Weller that the ton-mile cost is the proper basis for comparing the cost of motor-truck transportation with rail transportation, because the elements of flexibility of delivery and time of delivery demand careful consideration in determining the choice of method of transportation, I feel that he has brought up a very important subject for discussion when he reminds us that under present conditions the consumer of rail-transported goods pays his full proportion of the cost of roadway construction and maintenance, while the consumer of truck-transported goods shifts that portion of the cost to society as a whole. The exception to this would be in a state where motor vehicles were taxed as nearly as possible in proportion to their destructive effect upon the highway.

As an abstract proposition, that would seem to be the ideal solution of the whole problem; but I fear that the practical difficulties of equitably determining the rate to apply to each vehicle would be insurmountable, since neither weight or speed alone, nor the two together, are always the only or even the most important factors in determining the destructive effect of a vehicle.

There can be no doubt that within a moderate radius of the larger cities and between large cities situated comparatively close together, there is a marked tendency to transport all perishable and other high-class freight by motor truck, and it is probably but a question of comparatively few years until all of this work will be handled by motors, leaving the railroads to handle the through freight and the low-grade bulky freights.

This is going to mean an even more insistent demand than at present for good interurban roads and for wider roads to take care of the denser and—because of the rapid increase in the use of pneumatic tires on trucks—more rapidly moving traffic. Unless some satisfactory method of assessing the cost of building and maintaining these roads is worked out, the cost of these items is likely to be unjustly distributed.

As an instance, consider the State of New Jersey. The roads of that state, though the condition of many of them at present offers nothing to be proud of, represent the investment of large sums of money, yet I believe that more than half of the heavy traffic using the roads across the central portion of the state neither originates nor terminates in New Jersey and, naturally, the state receives no other revenue from this traffic than the small amount of the license fee from those trucks which are registered in New Jersey.

I do not, at this time, feel prepared to offer any solution of this important problem, but merely write because I feel, as Mr. Weller and many other engineers seem to feel, that we cannot have too much discussion on the subject. CHARLES F. DINGMAN.

Palmer, Mass.

Restudy of Column Loadings to Unify Column Formulas

Sir—Dr. Waddell's letter in your issue of Jan. 16, 1919, p. 155, is along the lines of the discussion offered by me on the report of the Committee on Steel Columns and Struts of the American Society of Civil Engineers. Many engineers can testify that this report has caused a doubt to be raised among designers, and not only among those who have no ready means of verifying the basis for the formulas that they must use, but seemingly among many that should have confidence in what has been done in the past and in their long experience in designing steel columns.

That there was not unanimity of opinion among the members of the committee in propounding the formula $20,000 - 100l/r$, between the limits of 80 and 100 l/r, with a maximum of 12,000 lb. is certain, and it is to be regretted that there was not a minority report to call attention to the fact that the formula was not one having the approval of the entire committee, thus saving the whole society from having to stand sponsor for it before structural engineers and engineers generally.

However, there is yet time for the various societies to get together and make every endeavor to arrive at an agreement on one straight-line formula for each grade of material, and discard the dozen or more that are now in common use to a greater or less extent. There should be no doubt that the Engineering Institute of Canada, of which the writer is a member, would join in such a movement. Extended use has not yet been made of the new parabolic formula which they have recently adopted. That formula would cause a great deal of difficulty in designing long spans, especially such a structure as the Quebec cantilever, for which was used the formula $17,500 - 70l/r$ with a maximum of 14,000 lb. or, when all the stresses had been included and

PRESENT FORMULAS FOR STEEL COLUMNS COMPARED WITH NEWLY PROPOSED FORMULAS

secondaries as well, a maximum of 18,000. This is for a medium steel with a yield-point of 35,000 pounds.

An investigation of the Niagara railway arch just carried out by the writer necessitated the careful study of the proper unit stresses to use, including column formulas; and as it was proposed to include all kinds of stresses in the totals, including secondaries and impact, the resulting total stress was in effect an equivalent dead-load stress, as is the case for any complete stress sheet at the present period. Therefore, the most logical column formula or curve of unit stresses for columns seemed to be one derived from the table of unit stresses, for the same class of steel and type of columns, established for the Hell Gate arch by Gustav Lindenthal. This is shown at the top of the annexed diagram, and is nearly 23,000 — $100l/r$ for the ordinary form of chord section and for steel with a yield-point of 33,000 lb., the maximum to be 20,000 lb. and the superior limit of l/r to be 135.

The diagram shows an essentially correct plotting of the principal column formulas that have received the sanction of engineers for various purposes, although some of them are of local adoption. All of the more commonly used ones lie in a zone between 12,000 — $60l/r$ and 18,000 — $60l/r$, and the new Canadian and the proposed A. R. E. A. formulas lie in the same zone. The mean of these two, or 15,000 — $60l/r$ is of course at the center of the zone, and is practically the same as the formula of the New York City building code. This is what the writer had adopted for a 1919 edition of "General Specifications for Steel Roofs and Buildings," but now that a still more unsettled condition of this subject has come about, it would seem advisable to await an adjustment and an agreement by all concerned. The lower limit of the zone represents the ultra-conservative opinion, and the upper limit the approach to what must eventually be adopted if the seemingly ultimate conclusion is to be reached. The practice of adopting a maximum stress limit below a certain value of l/r is to the writer by no means rational if the columns are properly detailed, except in the case of the formulas like the topmost one, giving values in excess of 20,000 lb., or corresponding values for other formulas for other grades of steel. The same formula for a given grade of steel might, however, be used for various classes of work, by adopting one set of limits of l/r for building work, one set of limits for highway bridges, and another set of limits for railway bridges. The maximum for such a formula might be considered 24,000 —$120l/r$, with a maximum of 20,000 lb., and of course making the rest of the specification conform to the formula. This would entail a study of whether to adopt the use of the net section in designing the columns of a structure, after the method developed by Mr. Lindenthal on the Hell Gate arch, and of many other seeming refinements. The loading to be incorporated in railway specifications is also inseparably tied up to the unit stresses, and seems quite far from a final settlement. The limits would, as stated, be much greater in the value of l/r for highway bridges, and greater still in the columns and struts for mill buildings and similar structures.

When we study the very unsatisfactory condition as shown by the diagram, it would seem to be only a logical course for the American Railway Engineering Association to ask for conference committees from the American Society of Civil Engineers; the Engineering Institute of Canada; the state highway departments; the building departments of the larger cities; the bridge division of the National Highways Association, and similar other interested organizations.

The necessity would then present itself, in arriving at the proper formulas, of a careful selection and plotting of all of the column tests of the past, and the more recent ones, such as those made by the American Society committee, and those given in the more recent report of the Bureau of Standards, using of course only those tests made on fairly well designed columns and those which are reliable from every point of view. The lower lines in the zone too often represent formulas that took account of tests of columns that were improperly designed and detailed. The matter of end conditions,

especially for high buildings, should be settled and plainly defined.

The parabolic curve C on the diagram, beginning at 12,000, is the Canadian formula $12{,}000 - 0.3\ (l/r)^2$, and that starting from 13,000 is the proposed formula of the A. R. E. A.—$13{,}000 - 0.25\ (l/r)^2$. While they are comparatively simple, it is by no means certain that it is wise to go back to curved formulas after having abandoned them to a very great extent in favor of the more-simple and, in the opinion of many, equally exact straight-line formulas. The restudy of all of the available data will, however, determine this to the satisfaction of all concerned.

CHARLES E. FOWLER,
Consulting Engineer.

Corrects Statement of Levelman's Pay

Sir—Replying to the letter of R. Reimann in your issue of Jan. 30, 1919, p. 253, relative to the pay of a levelman *on a line now owned by the Baltimore and Ohio R.R.*, the line referred to was the Pittsburgh Southern R.R., acquired and now operated as the Wheeling division of the Baltimore and Ohio.

It is a matter of congratulation that the pay of levelmen is at least $145, which shows that there has been an advance.

E. N. GINEER.

Buffalo, N. Y.

Engineers' Salary Schedule Proposed

Sir—On account of the responsibility resting upon the railroad technical engineer for the success of transportation, it is important that he receive proper recognition in the way of pay. This is of interest and of importance to the public.

Had the engineer been adequately represented in the hearings before the Wage Board of the United States Railroad Administration prior to the issuing of Order No. 27, that order might not have been totally oblivious of his work. A conference of railroad technical engineers will be held in Chicago Mar. 17 to discuss economic questions of interest to the profession. Among these is the application of overtime rules of the Railroad Administration. Many engineers are opposed to overtime on the ground that it does not permit the best work. They hold that the monthly salary should be adequate and that overtime should not be considered.

The inclosed schedule, which was prepared by the American Association of Engineers and approved by its railroad committee, consisting of W. H. Finley, E. H. Lee and W. W. K. Sparrow, is the first attempt made by an organization of engineers to say what salaries should be paid. This is not a final schedule but a preliminary one, and comment is invited. It is being sent to managers and to others interested in this subject. You will note that there is no attempt made to take up specialties in the railroad field, but it does lay the groundwork for uniformity in classifying the various positions in railroad engineering departments.

Chicago, Ill.

C. E. DRAYER,
Secretary, American Association of Engineers.

Over $5,000,000,000 Worth of Minerals Mined

Mineral products worth more than $5,000,000,000 were produced by the mines of the United States in 1918, according to estimates by the United States Geological Survey. This, it is estimated, is more than $150,000,000 increase over 1917, and nearly $2,000,000,000 more than 1916. The estimates show that the output of pig iron, copper, ferro alloys, lead, zinc, gold, silver and aluminum was valued at slightly under $2,000,000,000 in 1918, as against a little more than $2,000,000,000 in 1917, whereas the nonmetallic products, the principal of which are coal, petroleum, clay products, cement and natural gas, were valued at more than $3,250,000,000 in 1918, as against less than $3,000,000,000 in 1917. These figures, as announced, are preliminary estimates of the production of 1918.

SCHEDULE OF MONTHLY SALARIES FOR TECHNICAL ENGINEERS RECOMMENDED BY AMERICAN ASSOCIATION OF ENGINEERS

	Monthly Salary: Railroads Having Over 5,000 Miles of Track	Monthly Salary: Railroads Having Less Than 5,000 Miles of Track
Chief engineer: In charge of entire railroad system, responsible for all engineering work and organization, including valuation	Salaries commensurate with duties performed	
Assistant Chief Engineer: In charge of portion of line or entire territory; reporting to chief engineer; responsible for such work as may be assigned to him by the chief engineer	Salaries commensurate with duties performed	
District Engineer: In charge of two or more divisions; reporting to assistant chief engineer in charge of that territory; responsible for all maintenance of way and minor construction	$425	$375
Assistant District Engineer: Same territory as district engineer—like responsibilities. Reporting to district engineer	350	300
Division Engineer: In charge of one division; responsible for all maintenance of way and permanent way work	375	350
Resident Engineer: In charge of one residency; reporting to division engineer. In charge of construction work only. This position not required for maintenance of way or permanent way work	275	275
Assistant Engineer: Acts as assistant to division engineer, assistant district engineer, and assistant chief engineer. Responsible for such duties as may be assigned him	275	275
Chief Draftsman: Reports to chief engineer or assistant chief engineer; in charge of general drafting room at principal headquarters	Salaries commensurate with duties performed	
Engineer of Bridges: Reports to assistant chief engineer or chief engineer. Responsible for maintenance and construction of all bridges—wooden, steel and concrete	400	350
Valuation Engineer: Responsible for all valuation work on entire system. Reports to assistant chief engineer or chief engineer	400	350
Assistant Valuation Engineer: Reports to valuation engineer; has like responsibilities	350	275
	Permanent Work, One Year or More	Temporary Work, Less Than One Year
Instrumentman: Reporting to engineer or chief of his assigned department	$200	$225
Rodman: Reporting as assigned	125	150
Tapeman: Reporting as assigned	100	120
Designer: Reporting to chief draftsman or as assigned, and qualified to prepare original design on engineering or architectural work	250	275
Draftsman: Reporting to chief draftsman or as assigned, or general drafting work involving general detailing	160	200
Junior draftsman: Reporting as assigned and qualified for general drafting room work	115	160
Tracer: Reporting as assigned, and qualified to prepare neat tracings on special designs	110	120

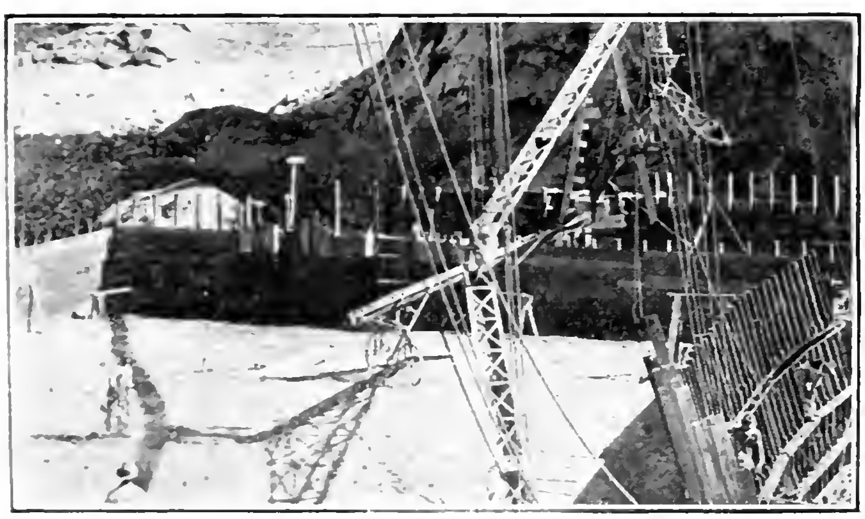
Hints for the Contractor

DETAILS WHICH SAVE TIME AND LABOR ON CONSTRUCTION WORK

Home-Made Bicycle Support for End of Concrete Chute

IN THE construction of the Gibraltar dam, near Santa Barbara, Cal., there was built on the job a two-wheeled support for the end of the concrete chute. This device made it easy to shift the delivery end of the chute, thereby saving the expense involved in a separate block-and-tackle support or the delay occasioned in moving when the delivery section is supported on a trestle.

As shown in the accompanying illustration, the "bicycle" was made up of two wheels taken from an ordinary concrete buggy and mounted on a frame built



THIS CHUTE HAD BICYCLE TO RIDE AROUND ON

up of scrap-iron and short pieces of old pipe. By putting a through bolt and nut in the head of the fork supporting each wheel, and keeping the bolt fairly tight, the wheels could be kept steady in any direction after being aligned by hand. Thus, for moving ahead the wheels would be directed at right angles to the frame, or for swinging around the swivel joint they would be placed parallel to the frame, and wherever placed would retain their relative positions as the end of the chute was moved to a new location.

A slope of 3 to 1 was standard for concrete chutes on the job, so the irons used to attach the bicycle frame to the chute were made accordingly. To change the device to another section of chute it was only necessary to remove the bolts, two on either side where the frame was attached to the lip of the chute, and make the same connections on the new chute section.

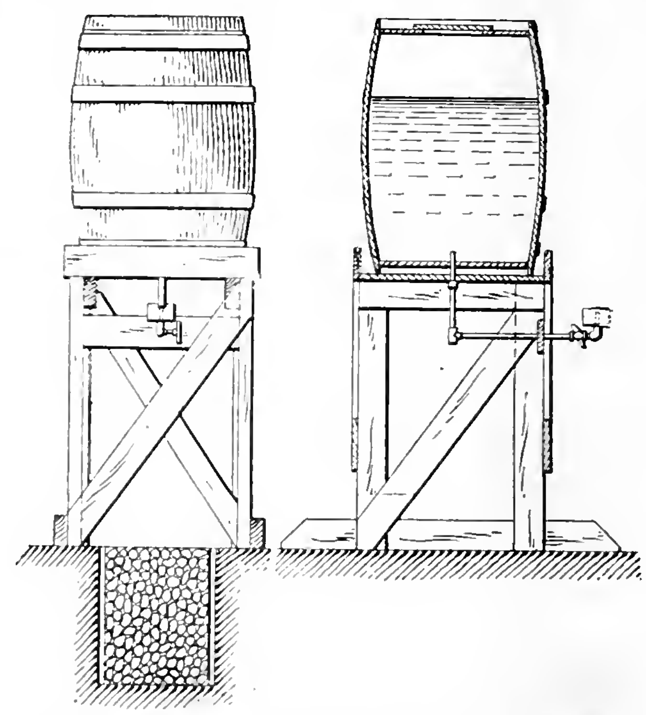
The device was developed by Mr. Slocum, one of the superintendents for Bent Bros. and W. A. Kraner, contractors on the Gibraltar dam.

Camp Drinking Fountains Improvised From Barrels

DRINKING water was distributed by means of bubbling fountains improvised from barrels to workmen constructing the extension to Camp Custer. As shown by the drawing, 50-gal. casks were mounted

Other Articles in This Issue of Interest to Contractors:

upright on stout wood frames 2 x 2 x 3 ft. A half-inch connection in the cask bottom connected with ¼-in. pipe to the bubble jets. These were set in ordinary pint tin cups so that the lips of the drinkers would not touch the jets. The jets were also slightly inclined to prevent the water from falling back on itself. Perforations in the tin cup permit it to drain out. To prevent formation of a puddle to breed mosquitoes a sump, as shown, is built under the bubblers. This sump



BUBBLING FOUNTAINS SUPPLY DRINKING WATER TO WORKMEN AT CAMP CUSTER

is 1 x 1 x 1½ ft., and is filled with broken stone. The barrel is filled through a hinged door in the top.

At the height of operations, when the working force was about 2500, one driver and two helpers with a wagon kept all the fountains supplied with fresh water.

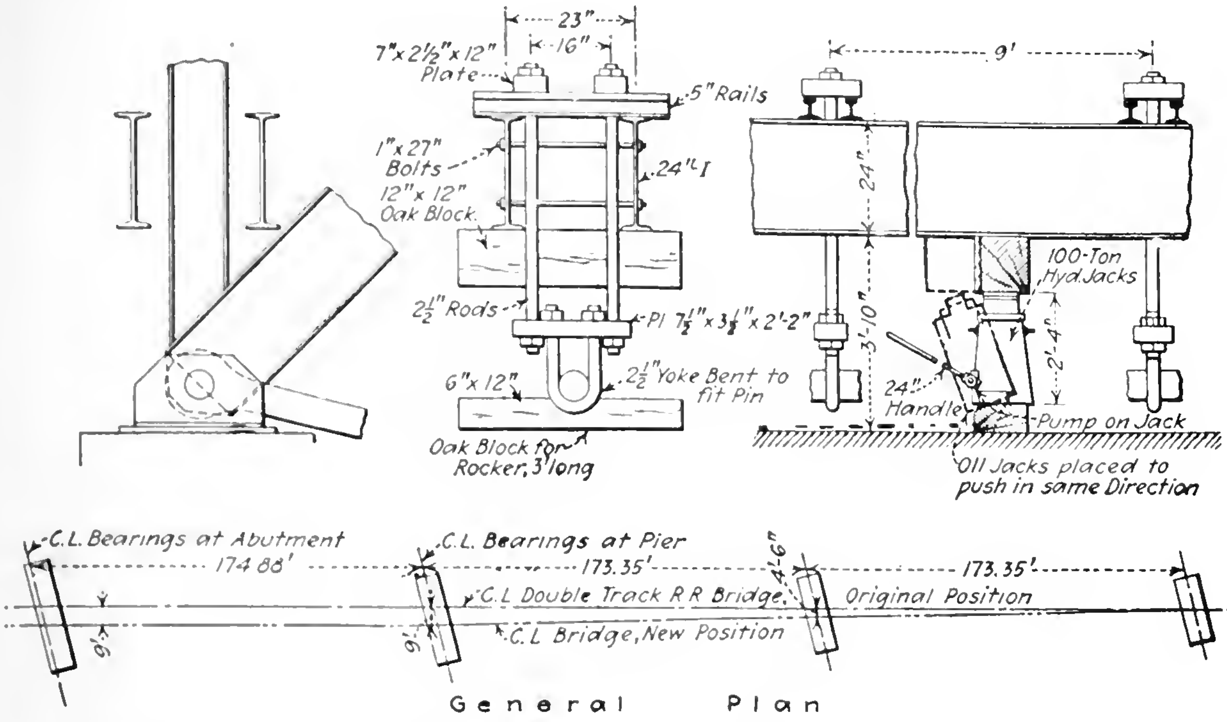
Camp Custer was built by the W. E. Wood Co., Detroit, Mich., contractors, under the direction of Maj. T. A. Leisen, constructing quartermaster, and Samuel A. Greeley, supervising engineer.

Skew Bridge Spans Shifted Laterally by Jacks on Rocker Blocks

By S. A. Snyder

Field Superintendent, The Foundation Co., New York City

A UNIQUE method of shifting bridge spans was recently applied successfully at the Delaware River bridge of the Central R.R. of New Jersey at Easton, Penn. Three 174-ft. double-track railroad spans were



DETAILS OF JACKING SCHEME FOR SHIFTING BRIDGE SPANS LATERALLY

shifted 9 ft. south when it became necessary to build a new bridge of heavier design alongside of the old bridge. The sketch herewith indicates in outline the details of the method used. An acetylene torch was first applied to cut through the plates of the main shoes, which were made in one piece and had to be divided in order to allow independent movement of the spans.

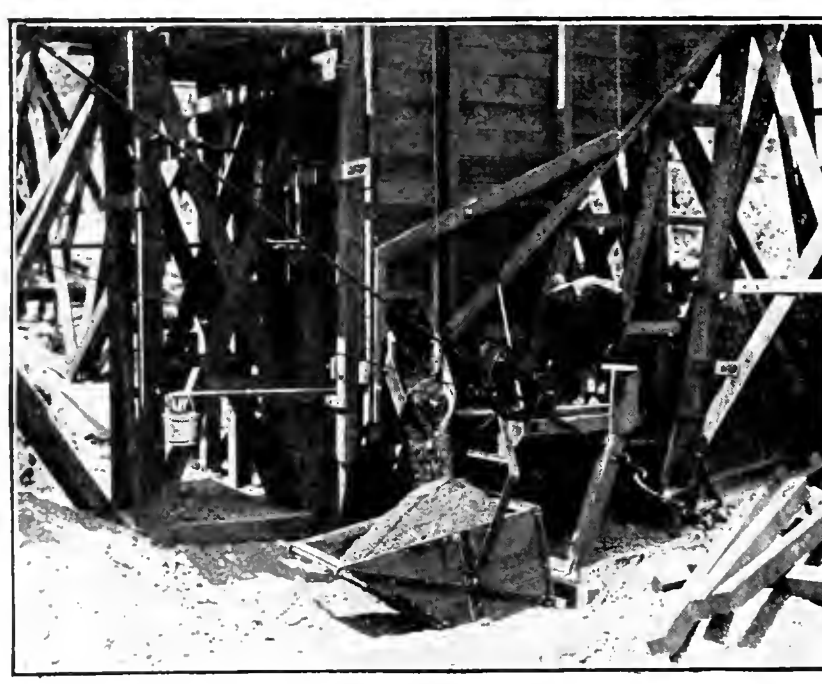
A special yoke, of 2½-in. diameter, bent into the shape of U-bolts with 3½ x 7-in. steel yoke plates, was made fast under the end pins. Hanger bolts carried the load to the 24-in. 80-lb. I-beams, as shown in the sketch, by the 5-in. rails laid across these beams and the 7 x 2½-in. plate on top. Oak blocks, 12 x 12 in. in size, were fastened to the under side of the beams with nails, and below them 100-ton hydraulic jacks were erected upon the rocker blocks 6 x 12 in. in size.

Twenty-two jacks in all were used, and two men were stationed at each. At the given signal all started pumping at once; when the spans lifted the jacks rolled on the rocker blocks, moving sidewise and endwise at the same time to allow for the skew. The movement was made in six working hours by The Foundation Co., 233 Broadway, New York, with the writer as field superintendent, under the general direction of A. E. Owen as chief engineer of the Central R.R. of New Jersey.

Single Line Automatic Dump Skip Makes Speedy Record

TO ELEVATE mixed sand and gravel to screens, on the dam near Santa Barbara, Cal., a wooden skip was designed to be operated on a cableway by a single line, and to dump automatically. The skip was supported from a two-wheeled carrier, as shown in the illustration, in such a way that when full it balanced in a stable position. The forward end of the skip carried a round bar projecting on either side. As the skip passed over the bunkers these projections were caught by slots in a pair of rails, thus stopping and holding the forward end. Then, as the carrier was advanced a few feet farther, the skip would revolve around the pins on which it was supported, and turn over into dumping position. The slope of the forward end of the skip, as shown, insured a clean delivery of materials. The weight of the skip and the steep angle of the cableway (something over 30 degrees) were found sufficient to secure a prompt return to the loading point when the hauling line was slacked away. The skip was built up on the job partly for economy and partly because all equipment for this work had to come through a tunnel with a maximum clearance of 42 x 46 inches.

The skip was devised by W. A. Kraner, of Bent Brothers and W. A. Kraner, contractors on the dam, and worked so successfully that two of them will be used when the work is resumed after the season's high water. During the season just closed the skip regularly made a round trip per minute, handling 50 cu.ft. of material on a 185-ft. lift.



THIS SKIP SAVED MONEY FOR THE CONTRACTOR

Cost of Resurfacing Street Excavations in Los Angeles

Resurfacing of street excavations to the amount of 579,062 sq.ft. has been done at Los Angeles for the following unit costs, according to the annual report of the Engineering Department. The names of the various pavements included and the unit cost per square foot for replacement are as follows: Asphalt, 27.31c.; macadam, 16.16c.; brick, 33.34c.; granite block, 18.67c.; concrete, 17.58c.; oiled gravel, 10.51c.; streets not oiled, graveled nor paved, 0.42c.; sidewalks, 18.69c., and curb per linear foot, 43.39c. All excavations are taken care of by city forces under the supervision of a city foreman, which method is reported to be both satisfactory and economical.

NEWS OF THE WEEK

New York, February 13, 1919

Conference Promotes "Build Your Own Home" Movement

Discusses Legislative Measures Whereby Loan Association Securities May Be Made Available

At a recent conference held in Washington ways and means were discussed by which legislation may be enacted to make negotiable the securities of the building and loan associations, for the purpose of financing the "Build Your Own Home" movement. The conference was called by F. T. Miller, director of the Division of Public Works and Construction Development, Department of Labor, and was held in the offices of the division in Washington, D. C. A number of delegates representing the legislative committee of the United States League of Local Building and Loan Associations were present.

It was announced by Mr. Keesler, president of the league, that a caucus had been held previously to the meetings. The Solicitor of the Treasury was present at the caucus, which decided informally upon the following:

"A law should be advocated modeled somewhat upon the Federal farm loan act and somewhat upon the provisions of the act establishing the Land Bank of the State of New York—in other words to establish home loan banks in each Federal Reserve district, providing for small fixed capital and safeguarded by proper restrictions, of which banks the local building and loan associations would become stockholders. These would be authorized to accept building and loan collateral from member associations and issue debenture bonds therefor. Such bonds and the assets of the home loan banks would be declared instruments of the United States Government and exempt from taxation."

The league has a membership of 7269 associations with a collective individual membership of 3,838,612. It was stated that it had loaned all its available money and that it was now six months in arrears in making loans. In the present condition of affairs, the members are unable to assist the construction movement because of the non-negotiability of their assets, but, it was pointed out, if this could be remedied, the associations could make loans for home-building purposes to a very large extent.

Their assets, it was stated, which are estimated at $2,000,000,000, are for the most part first real estate mortgages. These are not acceptable at the Federal Reserve or national banks, and in many states are not transferrable by state.

American Delegates to Paris Engineering Congress Report Conditions in France

Describe Waterways, Road Situation, Lens Mines, Hydro-Electric Conditions and Ports—Franco-American Commission Proposed

That French engineers do not desire help from American engineers, except certain specialists, was again emphasized at a large meeting of the New York members of the four national societies in the auditorium of the Engineering Societies Building on Feb. 10. Most of the delegates to the French engineering congress in Paris were present and informally reported on the trip to France and their impressions of the French attitude and engineering conditions there. Col. H. S. Crocker, vice-president of the American Society of Civil Engineers, presided.

This delegation was invited by the *Société des Ingénieurs Civils* to visit a Paris Congress of Engineers, as described in our issue of Nov. 28, 1918, p. 1003, and attended various sessions and committee meetings from Dec. 16 to Jan 18. A significant action of the Congress was reported—it proposed a permanent Franco-American International Commission.

Dr. George F. Swain, past president of the civil engineering society, who was made chairman of the delegation after Maj. J. S. Case left for Italy, described the work of the Congress and stated that it included public men and business men. M. Millerand, former Minister of War of France, was chairman of the Congress. It was desired to consult American engineers with reference to three problems: (1) Changing war industries to a peace basis; (2) rebuilding the devastated districts, and (3) the great engineering problems. The last were discussed by the Congress through committees on ports, navigable waterways, roads, waterpower, and technical education. Reports are to be prepared by the American delegates and sent back to the Congress.

Dr. Swain described their visits to various ports in southern France, Grenoble, Marseilles, and Lyons, where they were entertained by the Chambers of Commerce, and said that French engineers are anxious to coöperate and learn American methods, having been surprised by the speed of the Army construction in France. He reported the action of the Congress in voting to ask for the permanent Franco-American International Commission. The delegates left a preliminary report, answering questions and commenting on the action of the Congress on various subjects.

Employment

Professional and Special Section, United States Employment Service; Thomas T. Read, manager Eastern zone, 16 East 42nd St., New York, and Ward R. Robinson, manager, Central and Western zone, 63 E. Adams St., Chicago.

American Association of Engineers, F. H. Meyers, manager, 29 So. La Salle St., Chicago. Service to members only, but Army or Navy engineers in uniform who are eligible to certified membership may join without payment of entrance fees or dues while in uniform and for six months after discharge.

Navigable Waterways and Technical Education

Dr. Swain stated that France had spent more than any other European country in improving her inland waterways and expected a great increase of commerce through her ports to replace Hamburg and Bremen, and that they are making plans for developing canals and navigable rivers. He commented on the lack of economic studies, and comparison with railroad costs. The state assumes all the burden; but he claimed that the present emergency required more economic study to insure sound economy.

Technical education in France is more theoretical than in this country, but many changes in their educational methods are being considered. The desirability of exchanging students with France was discussed at the Congress, and hopes were expressed that more American students would go to France for technical study, rather than to Germany as in the past. The French are hoping to change their previous restrictions, which have discouraged the attendance of American students.

George W. Tillson, one of the civil engineering delegates, discussing the roads situation in France, stated that the French wish to build for permanence, but are very conservative. They believe in the use of asphaltic macadam, using the penetration method rather than the mixing method, apparently because the latter is more costly in requiring larger plant. The American engineers urged concrete and brick for such permanent roads.

Mr. Tillson discussed the methods of financing for road building, stating that many French roads are paid for by fifteen annual instalments, the cost thereby being at least 65 per cent. more.

E. G. Spilsburg, who represented the Institute of Mining Engineers, described a trip to Lens and the devastation in the coal region. He stated that not a building was standing in Lens, where there were sixty mines, eighteen of which were operating before the war. All the head frames had been leveled, being pulled over by motor trucks after the legs were cut by oxy-acetylene flame, if they had not been blown down by shells. The mines were flooded by laying pipes from the Somme Canal. He stated that it would require 30,000 horsepower per year to unwater the mines, and that probably coal mining would begin about nine months from next spring. He insisted that the French were not seeking the help of foreign engineers, except specialists; they expect to use their own machinery and man power.

AGRICULTURE, FINANCE AND HYDRO-ELECTRIC POWER

George W. Fuller, one of the civil engineering delegates, discussed the subject of agriculture and finance, saying that France had increased her government expenses by at least $2,000,000,000 per year as a result of the war and had lost 2,000,000 men from active life. The transition to peace is relatively slow, the rehabilitation program being quiescent, due to the fact that the railroads are tied up in rationing Belgium, Alsace-Lorraine, and French devastated regions. The French are inclined to wait for the results of the Peace Conference, and the reparation and indemnity funds to be asked from Germany. They also await Parliamentary elections soon to occur.

Lewis B. Stillwell described the three regions for waterpower development in France—the Alps, drained by the River Rhone, the Pyrenees, not yet much developed, and the highlands in the south of France, where low heads are available, with good locations. The total estimated horsepower developable is from 4,500,000 to 6,000,000. After mentioning some of the historic developments of high-head plants, he stated that we could teach the French nothing in the technique of hydroelectric application to industry, except perhaps in the magnitude of operation. An electrolytic process for making iron pipe by depositing iron on drums was described, the plant being near Grenoble. The French believe in taking industry to the waterpower. The delegation's preliminary report recommended that the coal regions should be connected up with the waterpower centers. They are making a serious effort to standardize frequency and potentials, so as to allow inter-connection in the future—a frequency of 50 has been recommended by the Paris Congress.

PORT DEVELOPMENT—MARSEILLES TRIP

A. M. Hunt—one of the civil engineer delegates—described the port developments in France and the French plans for an east and west railroad to Basle, Switzerland. They expect to act promptly and one plant is already being developed at Saint Lazaire. They ask a report on the methods of handling freight at ports in America, especially for ports where there is a great range of tide, 16 to 20 ft., as in France. Floating docks are also greatly needed.

One of the most stirring addresses of the evening was the last, by Nelson C. Lewis, a civil engineer delegate, describing the "Smiling Valley of the Marne" which they passed through on the first sunny day of their trip. He pictured the great changes in France, the separation of families, and the question was raised whether many of those who are now in southern France would desire to return to the devastated districts. The problem of women in industry is causing serious complications, and the French are attacking the industrial essentials before they can return to their artistic development. He cited the figures on the devastated areas, which include 6000 sq.mi. in the north of France, quoting the total as $13,700,000,000 as the estimated amount of this destruction and pleading for the necessity to force Germany to pay every cent of this as reparation.

Position Offered Parsons as Transit Construction Commissioner

Governor Smith of New York has offered to Col. William Barclay Parsons the position of director of rapid-transit construction in New York City. Colonel Parsons is still in France, and a reply to the offer has not yet been received. According to the Governor's recommendation to the legislature, regulation of public utilities is to be separated from the direction of construction work, and a single commissioner is to administer the latter. Up to the present the legislature has not acted on the recommendation, but some form of revision of public-utility work in New York State is considered certain.

Departments Report on Canals

Two reports relating to canals have just been made public by Congress. One is a report from the Secretary of Commerce to the Senate on the Atlantic intracoastal canal system; the other, a report from the Chief of Engineers through the Secretary of War to the House of Representatives on the Houston ship channel in Texas. The Atlantic canal report goes thoroughly into the proposed canal system paralleling the Atlantic coast and some distance back from it. It includes descriptions of the Cape Cod Canal, the New Jersey Canal and the Chesapeake & Delaware Canal, all of which make up the proposed connected system. The Houston report is in effect a recommendation by the Chief of Engineers to extend this channel, which now connects the hitherto inland city of Houston with the Gulf of Mexico.

An Innovation in Motor-Truck and Good-Roads Boosting

In Macon, Ga., an innovation is being undertaken by the Chamber of Commerce to promote the use of motor trucks for hauling produce and freight to and from the suburban districts. The test will take place Apr. 3, and more than 250 trucks will be used.

The plan is to have six motor-truck fleets leave the city in six directions, proceeding to terminals approximately the same distance from the city. On the outgoing trip they will be loaded with merchandise, and on the return trip with livestock and farm products. A parade in Macon before the start and a rally at each terminal point, with stops along the way, will be used to advertise the experiment.

Motor-truck dealers and manufacturers, together with merchants and farmers, have promised their coöperation, and it is planned to have with each train specialists whose duty it will be to record every phase of the test, including mechanical operation and cost, bridge and road conditions, tonnage, time, etc. The plan is to demonstrate what can be done with motor trucks over good roads.

Engineering Council Appoints License Committee

The question of the licensing of engineers has been taken up by the Engineering Council, and a license committee has been appointed, with the following members: Chairman, T. L. Condron, Chicago, Ill.; F. C. Shenehon, Minneapolis, Minn.; Farley Gannett, Harrisburg, Penn.; John H. Dunlap, Iowa City, Iowa; Arthur M. Greene, Jr., Troy, N. Y.; Caleb M. Saville, Hartford, Conn.; James H. Herron, Cleveland, Ohio; A. M. Schoen, Atlanta, Ga.; John Klorer, New Orleans, La.; Philip N. Moore, St. Louis, Mo.; A. Lincoln Fellows, Denver, Colo.; C. H. Snyder, San Francisco, Cal.; and Amos Slater, Seattle, Wash.

The country is being divided into districts by the chairman, to be assigned to the various members of the committee for the gathering of information from state officers and others, relative to existing and proposed legislation on the subject of licensing engineers and architects. The committee is already receiving inquiries for information, and assistance on this subject from many quarters.

Build a Home Movement

(*Concluded from page 348*)

law. Because of the excellent character of the securities, members of the associations were of the opinion that they would be able to rediscount at a comparatively low rate. The associations, it was said, did a business in 1917 of $1,250,000,000, at an expense of 0.00875 per cent.

Motion Pictures Show Essentials In Making Concrete

At the meeting of the American Society of Civil Engineers in New York City Feb. 19 Nathan C. Johnson, consulting concrete engineer, will present a moving-picture film which illustrates the essentials, in materials and mixing, in the making of good concrete. The film embodies the results of Mr. Johnson's five years' study of concrete with the microscope and the motion-picture camera. The early results were presented in *Engineering Record* of Dec. 4, 1915, p. 684.

The film takes up the materials and processes through which they are put, examining each material and each step in the mixing and placing in its effect on the final product. The effects of erroneous methods are shown as well as those of correct procedure. Throughout the film, which consists of two and a half reels, are full explanations of the various parts of the picture, so that it is entirely self-explanatory. However, in presenting it Mr. Johnson will use a type of projector that allows the film to be stopped for any length of time, so as to permit full explanation and discussion.

Among the most interesting features are sections of the film which show setting and other operations; this picture was taken over long periods. One particular portion was made with exposures extending continuously over 50 days, a motor-driven camera being used for the purpose.

Kansas Engineering Society Wants State Aid for Roads

At the annual meeting of the Kansas Engineering Society held at Topeka, Jan. 30-31, the retiring president, C. M. Buck, pointed out the necessity for hard-surfaced roads, and urged the society to use its influence with the state legislature to have measures passed allowing state aid on roads and bridges and increasing the salaries of county engineers. A special legislative committee was appointed to prepare resolutions.

Dean Shaad, of the school of engineering of Kansas University, spoke on engineering education, emphasizing four main points: (1) Vocation schools; (2) designing, covering the courses generally included in a technical curriculum; (3) executive and administrative, covering special courses in these fields; (4) good citizenship, taught in the entire course.

Lieut. K. P. Cecil discussed the subject of artillery at the front, explaining three methods of range-finding—the three-point-sound method, the flash range, and the high-burst range, where trial shots are made above the target that they may be observed by the range-finders. The Lambert system of coordinates as used in mapping the battlefield was explained. Capt. L. R. Tillotson presented a paper on "With the Engineers in France." He praised the roads of France, and said that they were a key to the success of the army. Railway and harbor improvements were described in detail. Maj. Clark Mandigo gave a short description of some of the engineering construction that was undertaken at the front.

Resolutions were adopted to be submitted to the four national engineering societies, requesting their aid in the matter of increasing salaries. The following officers were elected: President, A. A. Potter, dean of engineering, State Agricultural College, Manhattan; vice-president, H. A. Rowland, McPherson; secretary-treasurer, Lloyd B. Smith, Topeka.

Research Assistantships Available at University of Illinois

There will be eight vacancies in the research graduate assistantships, Engineering Experiment Station, University of Illinois, Urbana, Ill., at the end of the current academic year. Two other such assistantships in gas engineering have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry.

Nominations, made from applications received by the director of the station not later than Mar. 1, are subject to the approval of the president of the university and are based upon the character, scholastic attainments and promise of success in the principal line of study or research to which the candidate intends to devote himself. Preference is given to those applicants who have had some practical engineering experience following the completion of their undergraduate work.

Bill Introduced To Promote Industrial Education

Representative Caldwell of New York on Feb. 4 introduced a bill into Congress to provide for further educational facilities by requiring the War Department to loan certain machine tools not in use for Government purposes to trade and technical schools and universities. Each institution so equipped shall be responsible to the United States, under regulations to be prescribed by the Secretary of War, for the proper care and safe return of such equipment when demanded, ordinary wear and tear excepted.

Technical Editors Make Trip to War Areas of Europe

Notes on Journey of Observation to England, Belgium and France at Invitation of British Government

Last October Great Britain, through its Ministry of Information, invited a party of 15 editors and publishers of technical and business papers in the United States to visit England and France, in order that civilian intercourse might continue in spite of the obstacles interposed by military regulations. While in Europe the travelers attended many social functions, but back of the luncheons and dinners there was a serious purpose, the former being merely the medium chosen for its accomplishment. It was a tribute to the technical and business press of America of which, says one of the returning editors, we may well be proud.

Notes of the Trip

The following notes have been abstracted from an article by one of the party, H. C. Parmelee, editor of *Chemical and Metallurgical Engineering.* Among others on the trip were Samuel O. Dunn, editor of *Railway Age*, Chicago; William W. Macon, managing editor of *The Iron Age*, New York; Floyd W. Parsons, editor of *Coal Age*, New York; H. C. Estep, editorial director, Penton Publishing Co., Cleveland; and Arthur J. Baldwin, vice-president of the McGraw-Hill Co., Inc., New York, Mr. Parmelee writes:

"Before leaving England we were entertained at luncheon by Lord Northcliffe, owner of the London *Times*, at Printing House Square. For this occasion our host had invited leaders of industry and political thought to meet and talk with us, and we counted the affair one of the most instructive we had attended. Sir Robert Hadfield spoke of the possibility of giving workmen a summer holiday with pay instead of making them take their holidays on their own time.

"A brief visit to Sheffield University allowed an hour with Prof. J. O. Arnold, who is at the head of the department of metallurgy and engineering.

It is greatly to be regretted that work such as that Professor Arnold has done and is doing is not adequately supported. It seemed to me as though England had not yet risen to an appreciation of her technical men, despite the fact that they were the ones on whom she had to call when she was confronted by a foe skilled in technology and the application of science in the art of warfare. I was told that the Government had actually contemplated providing chemists for some of its works with the munificent salary of £125, about $625, per annum, a sum which would not attract a bottle washer in our American laboratories. This was but one instance of what seemed to me to be a lack of appreciation of

technical education, but I was told that a change is coming and that England is alive to the needs of research, coordination of industry and universities, and the value of technology in the national life. Incidentally, some excellent work has been done by such men as Professor Arnold and Sir Robert Hadfield, and we may expect some good papers from their pens.

"France gives one the impression of being somewhat dazed over her recent experience, and at a loss to know just where to begin to retrieve her lost fortunes. We had a number of dinners and luncheons with their leaders of industry, who said frankly that France was in the position of having to ask preferential treatment at the hands of the other nations. One gentleman even suggested that they would like to see French goods enter the United States duty-free, and American goods pay a duty on entering France. They are alarmed at the prospect of the Germans capturing world markets before France can even rehabilitate her factories and get new machinery in running order. The Germans return to factories that are intact, ready to turn out their products into world trade, while France must begin at the bottom and build again her principal industries. These are the things that worry France and are probably having something to do with the new terms in the extension of the armistice.

Gained a New Point of View

"We landed in New York on New Year's Day, glad that our home is in the U. S. A., but not forgetting the ties that must inevitably bind us closer to our English-speaking friends on the other side. One cannot experience two months of travel in foreign lands and contact with peoples with whom we have been united in a vital struggle without getting a new point of view, broader, larger, more comprehensive and sympathetic. We have been deeply impressed with the endurance and fortitude of the British and French, and we can but admire the high ideals that animate them in their approach to the solution of problems that concern the world's future welfare. Our own participation has been deeply appreciated, so much so that we are likely to be led into exaggeration of the importance of our part in the great struggle. At the same time our help is just as urgently sought in meeting the problems of peace, and to that end we must all lend sympathetic and broadminded aid."

No Federal Aid for Hudson Tunnel as Postal Route

Vote of the United States Senate, Feb. 7, defeated the Calder amendment to the Post Office appropriation bill authorizing Federal participation in building a vehicle tunnel under the Hudson River at New York. The amendment was held to be in order, but a vote on its adoption defeated it, with 12 votes in favor to 48 against.

Castle Formation by Engineers On Last Day Under Arms

The accompanying photograph of the 209th Engineers, Camp Sheridan, Alabama, was taken on their last day under arms, Jan. 21. The men were photographed from a tower 40 ft. high. The camera was 5 ft. higher, and the nearest edge of the castle formation was 57 ft. away.

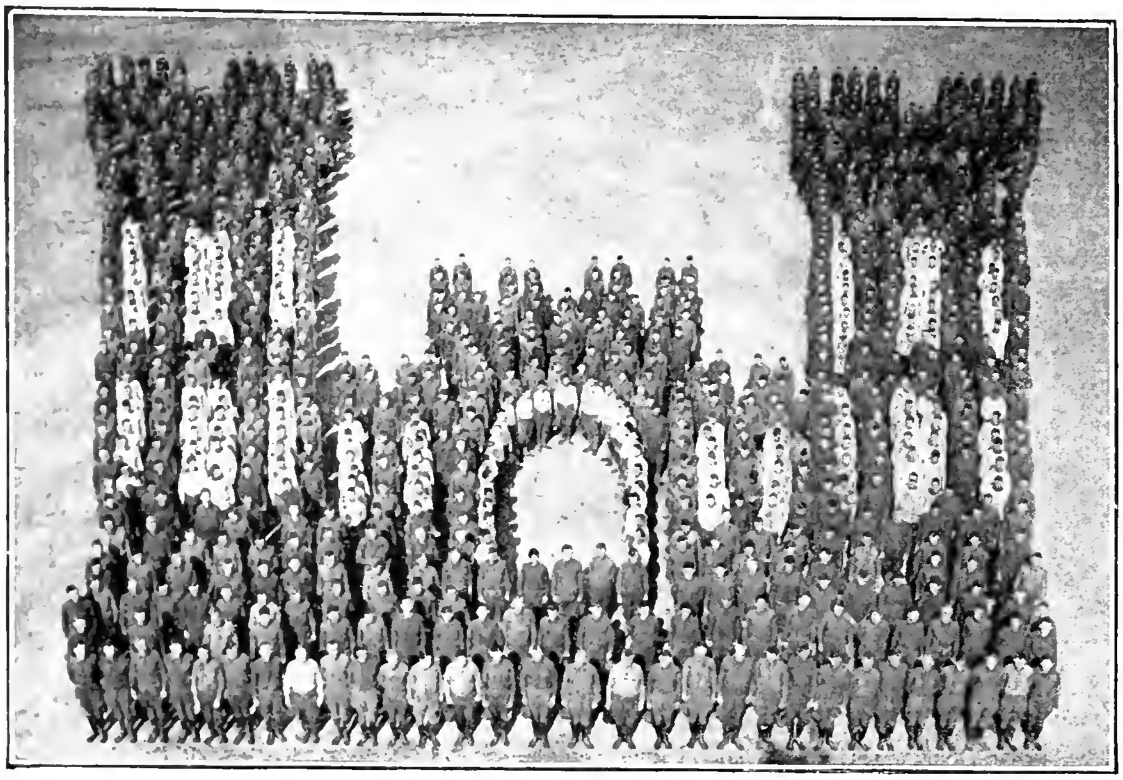

Photo copyright by G. F. Jennings, Montgomery, Ala.

209TH ENGINEERS IN CASTLE FORMATION PHOTOGRAPHED FROM 40-FOOT TOWER AT CAMP SHERIDAN, ALABAMA

The design called for 1000 men to fill in the castle, but only 925 were used. The design was made by Capt. D. C. McConnell, regimental topographical officer. A camera with a focal length of 14 in. was used. Col. Beverly Dunn, Engineers, was the commanding officer, and Lieut. Col. H. F. Cameron was second in command.

Propose To Take Office of County Engineer Out of Politics

Abolition of the elective office of county engineer in the State of Washington and the substitution of a superintendent of highways, appointed by the county commissioners to serve as long as he proves efficient, are the purposes of a bill that has been introduced in the state legislature now in session at Olympia. The bill is recommended on the ground that it would take the county engineer's office out of politics.

Qualifications of the superintendent of highways are set forth and include as a requisite that he shall be a civil engineer of recognized standing, shall have had a degree conferred by some college or university having recognized courses in civil engineering, and shall have practiced his profession in connection with highway engineering or railway engineering for two years, or, in case he does not hold such degree, he shall have practiced his profession for five years. The bill requires a bond in the sum of $5000.

The state shall pay the superintendent $100 a month, with traveling expenses, to be paid out of the county current expense fund. The bill contemplates that each county shall pay the superintendent an additional salary, the total not to exceed $5000 per year. It would make the county commissioners agents of the state highway department, and require that they appoint a competent engineer to work under direction of the department.

To Build Devil's Gate Dam

Bids for the construction of the Devil's Gate dam, a portion of the project to control floods in the Arroyo Seco, will be received by the Board of Supervisors of Los Angeles County, California, on Feb. 19. The estimated cost of the dam and appurtenances is $290,000. The structure will be an arch dam, with a maximum height above the stream bed of 100 ft. and a crest length of 310 ft. Cyclopean masonry will be used. On top of the dam there will be a roadway 20½ ft. wide and two 4½ ft. sidewalks. Besides a spillway with 10 openings, each 10 x 11 ft. in size, there will be an outlet tunnel. The latter will be controlled by three 7 x 9 ft. sluice gates. The site of the dam is near the northwest corner of the City of Pasadena. The drainage area above the site is 30 square miles, and the estimated maximum discharge is 11,400 sec.-ft. The proposed contract calls for beginning work within 30 days after the award and for completion by Dec. 19, 1919. The purpose of the dam is to control the flashy winter floods on the Arroyo Seco, a stream which joins the Los Angeles River near Elysian Park. J. W. Regan is chief engineer for the project.

Active Construction Delays As Labor Unrest Increases

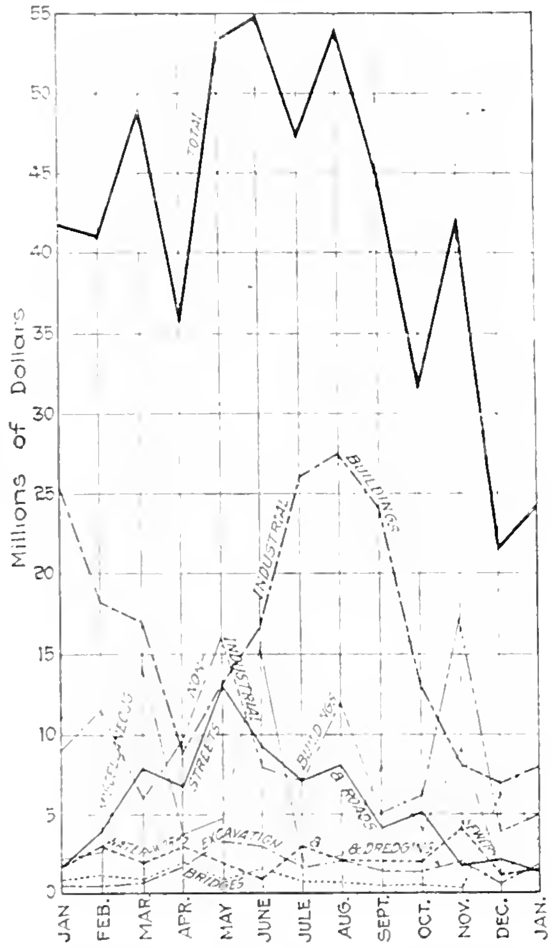
With Work Under Contract Millions Less Than Year Ago Proposed Work Shows No Advance Over Last Month

A survey of contracts let and projected work reported to *Engineering News-Record* shows that the hoped-for construction boom has not yet started. Contracts let, as indicated in the accompanying diagram, total some $20,000,000 less than those reported a year ago, and do not include the cantonment and other heavy war construction of the Federal Government at that time.

In an effort to learn the amount of public work that will be undertaken in 1919 *Engineering News-Record* sent letters and telegrams to all state highway departments, to state architects, and to city engineers of municipalities down to 50,000 in population. Of the replies received those on highway work were the only ones that were even approximately complete, and they totaled but a little over $350,000,000 for the year, which is only a small fraction of the annual amount of road work usually carried on throughout the country in normal times. The replies on municipal work were so fragmentary that they give no indications as to the probable trend of work, less than $60,000,000 worth being reported. A majority of the replies, however, show that, although the engineers were prevented from giving definite data on account of incomplete budgets, etc., they were alive to the gravity of the situation and were bending their efforts toward getting as much work started as possible.

The campaign for emergency construction started by the War Labor Policies Board in Washington deserves credit for some of this activity, the members of the board having made strenuous efforts to stimulate work to the utmost. Questionnaires have been sent to every city in the country to get information to enable the War Labor Policies Board to make a survey of the anticipated demand by municipalities for capital and labor. The data from the replies to date are still incomplete, but so far approximately $50,000,000 is reported, for which funds are already provided, $80,000,000 for work already authorized, the money to be raised by bonds, and $40,000,000 for work already, or likely to be, authorized and to be paid for by tax levies. Although small, these figures, it is believed, are more definite than those given in the table, since much of the latter amounts were derived from estimates. The figures in the table represent thousands of dollars.

It is evident, however, that the real start of construction work has not yet been made. It will be noted in the table that the proposed building construction amounts to but a bare $200,000,000, in spite of the dearth of building throughout the country and that contracts let in January amounted to less than $5,000,000. The amount of building construction in any one year cannot be definitely determined, but the pre-war work is variously estimated as amounting to between $2,000,000,000 and $3,000,000,000 annually. The war-



MONTHLY VOLUMES OF CONTRACTS LET REPORTED BY "ENGINEERING NEWS-RECORD"

time restrictions and the increase in population have been such that builders believe that for the next five years building construction will average in excess of $3,000,000,000 annually. It is evident that if the labor situation is to be relieved much heavier amounts must be reported than these to consider the work as even having started. The Bureau of Public Roads estimates that for every $1,000,000 worth of road work only 1000 men are employed, so that even should the total amount of estimated road work as shown in the table be converted into active projects, it would absorb less than 400,000 men. The Bureau of Public Roads recently requested the various state highway departments to send in an estimate of the requirements of labor that would be needed on the road work in the various states. Thirty-eight states replied, but only 29 gave definite figures. They report that they can use approximately 12,000 soldiers and sailors as skilled laborers, and slightly over 19,000 as unskilled. Those classed under skilled labor include masons, carpenters, quarry bosses, concrete finishers, road foremen, roller men and superintendents. Unskilled laborers were not classified.

Holding out for better prices of labor and material is, of course, the key reason for the delay. Better prices are hoped for, and a saving on construction work generally is believed possible by waiting.

The material men say, however, that there will be no decline in prices. Labor has stated that wages will not be reduced, and the owners, architects and builders are holding off for a more favorable season. Commenting on the situation, a prominent engineer in the cement industry pointed out the fallacy of the waiting, in that the threatened upheaval that will surely come if relief is not promptly forthcoming will be far more costly than the prosecution of work at the prevailing high prices.

CONSTRUCTION WORK PROJECTED FOR 1919

Bursting of Molasses Tank in Boston Charged to Bad Design

A steel tank for storing molasses belonging to the United States Industrial Alcohol Co., and standing on the company's ground in Commercial St., Boston, burst Jan. 15, and 19 persons were killed. The tank was full, having been filled, for the first time in its history, two days before. It was 90 ft. in diameter by about 50 ft. high, and contained 48 ft. 10 in. of molasses when it burst. In an inquest on the deaths, Municipal Court Justice Bolster found Feb. 8 that the building law was violated in the obtaining of a permit and the passing of plans for the tank, and that the city building department passed the plans without technical examination. The plans were found to be defective. They were drawn to an order for a tank to hold molasses weighing 11¾ lb. per gallon, with a factor of safety of 3. Plans were prepared by the iron works that built the tank.

No evidence was found to show that explosion or external violence brought about the failure, though the molasses in the tank was in a process of fermentation at the time. The court finds:

"My conclusion from all this evidence is that this tank was wholly insufficient in point of structural strength to handle its load, insufficient to meet either legal or engineering requirements.

"I am satisfied that the adequate and predominating cause of this accident was a bursting from internal pressure exceeding its structural strength."

Columbus, Ohio, Engineers Effect Close Relation With Council

As in the case of Atlanta, Ga., an unpaid advisory engineering board is to be appointed to assist the city of Columbus, Ohio, and its officials in the consideration of questions of a technical nature. The action is the result of an effort of the Columbus Engineers' Club, which presented the matter to the mayor and council Jan. 23. It is not proposed that the board should render services of a nature conflicting with the legitimate duties of engineers employed by the city or to interfere with the employment of consulting experts as needed, but it should act simply as an advisory board for the purpose of aiding in a determination of policies in regard to improvements, and in the settlement of difficulties or differences of opinion which may arise from time to time, either during the preliminary stages or during construction.

A bill to establish a state board of engineering registration and to regulate the practice of civil and mining engineering and surveying is being pushed by the club. The mechanical, electrical and chemical engineers and other classes felt that the bill should include them. The club went on record as favoring the licensing of professional engineers and the appointment of representatives of the different branches of engineering to take part in the meeting of the Association of Ohio Technical Societies, when the bill will be considered finally.

ENGINEERING SOCIETIES

Calendar

Annual Meetings

AMERICAN INSTITUTE OF MINING ENGINEERS: 29 West 39th St., New York City; Feb. 17-20, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION: 150 Nassau St., New York City; Feb. 25-28, New York City.

AMERICAN ASSOCIATION OF ENGINEERS, 29 S. LaSalle St., Chicago; May 13-14, Chicago.

The Providence, R. I., Engineering Society held its third annual banquet Feb. 12. Captain Delport, of the French Army, and Lieut. J. A. H. Muirhead, Royal Engineers, British Army, spoke on some of the engineering problems in connection with the armistice and reconstruction. Alfred D. Flinn, secretary of the Engineering Council, addressed the meeting on war activities of engineers. P. H. W. Ross, president of the National Marine League, spoke on "Public Participation in Maritime Affairs," and Leonard W. Cronkite of Boston, special agent of the United States Department of Labor, on "Co-operating for Reorganization." Newly released motion pictures were shown of the assembling and operation of 14-in. naval guns at the front, by Ensign C. S. McCrae, U. S. N. R. F., of the Naval Bureau of Ordnance.

The Colorado Society of Engineers was addressed by E. A. Moritz, of the United States Reclamation Service, on "The Engineer's Part in Reconstruction," at the third annual banquet of the society Jan. 25. A. L. Fellows, irrigation engineer, United States Department of Agriculture, read a paper on "The Future of Irrigation Engineering." Other papers read were: "Reconstruction and Good Roads," by T. J. Ehrhart, chairman of the Colorado State Highway Commission, and "Problems of Railroad Readjustment," by Arthur Ridgway, assistant chief engineer of the Denver & Rio Grande R.R. It was recently voted to change the name of the society from the "Colorado Society of Civil Engineers" to the "Colorado Society of Engineers."

The Detroit Engineering Society was addressed Feb. 7 by Dr. W. F. Rittman, of the United States Bureau of Mines, who spoke on "Motor Fuel," the principal theme of the address being the potential supply of fuel. The society will hold a joint meeting with the Michigan Chapter of the American Society of Heating and Ventilating Engineers, Feb. 21, at which L. D. Royer, of the Power and Construction Department, Ford Motor Co., will speak on "The Measurement of Flow of Liquids and Gases by Means of the Pitot Tube."

The American Association of Engineers will hold a conference in Chicago Mar. 17, under the auspices of its railroad committee, to discuss a tentative report of the committee, including the alleged need of an association of all railroad engineers to look after their economic welfare, and to consider the application of Order 27, and supplements, of the United States Railroad Administration, especially with reference to overtime and classification of engineers and rates of pay. W. H. Finley, chairman of the committee, will preside.

The Engineering Council will hold its annual meeting Feb. 20 at the Engineering Societies' Building, 29 West 39th St., New York City. The first session of the meeting will be held at 2 p. m. and will be continued in the evening, if necessary.

The International Federation of Draftsmen's Unions, Chicago, Local 14, accepted 122 new members at the semi-monthly meeting Feb. 1. John Fitzpatrick, president of the Chicago Federation of Labor, installed the following new officers for the year: President, M. J. Brown; vice-president, C. H. Monger; recording secretary, E. Hemmer; financial secretary, F. Wizeszez; treasurer, H. Matthei; business manager, F. C. Brodman, 4954 West End Ave., Chicago.

The Illinois Section of the American Water-Works Association will hold its 11th annual meeting at Urbana, Mar. 25-26.

The Engineers' Club of Seattle elected the following officers at the recent annual meeting: President, H. E. Horricks; vice-president, L. Murray Grant; secretary, E. J. Bartells, and treasurer, Amos Slater.

The Technology Club, Syracuse, N. Y., was addressed Feb. 3 by George T. Hammond of Brooklyn, who spoke on sewage disposal, in light of the plan of the City of Syracuse for a complete system of disposal. City officials attended as guests of the club.

The Louisiana Engineering Society was addressed by Maj. A. M. Shaw on "The Construction Division of the Army," at the regular meeting held Feb. 10.

The Colorado Association of Members of the American Society of Civil Engineers held a regular meeting Feb. 8, which was addressed by Walter L. Drager on "Federal Ownership of Railroads." The subject was discussed by Charles W. Comstock and Arthur O. Ridgway.

The Brooklyn Engineers' Club will be addressed Feb. 13 by William H. Grove, electrical engineer, Republic Engineers, Inc., New York City, who will speak on "A New 66,000-Volt Steel Tower Transmission Line in the Steel

Mill District of Ohio." A meeting of the club will be held Feb. 20, at which Walter E. Truesdell, of Joseph H. Wallace & Co., will speak on "Wood Pulp Machinery."

The Engineers' Club of Philadelphia will be addressed by Joseph A. Steinmetz on "News from the Peace Zone," at the weekly luncheon Feb. 18.

The Rochester Engineering Society, Rochester, N. Y., will hold its regular monthly meeting Feb. 14.

Personal Notes

Readers who are returning to civil life from military, naval or other Government service are strongly urged to send in items about themselves and about their friends who are in similar situation. Items should give former position, describe character of military or other service and state the civil work to which the engineer or contractor in question is going. In the case of those with service abroad, information regarding the activities of the units to which they were assigned is especially desired.

J. H. Knowles, bridge engineer, Western Pacific R.R., Tidewater Southern R.R., and Deep Creek R.R., has been appointed chief engineer in charge of construction and maintenance of way and structures, under Federal Manager W. R. Scott, sucsucceeding T. J. Wyche, resigned.

Capt. D. A. Tomlinson, until recently assistant senior instructor in orientation, Coast Artillery, Fort Monroe, Va., has become special agent, Professional and Special Section, United States Employment Service, with headquarters at 63 E. Adams St., Chicago, under Ward R. Robinson, manager, Central and Western Zone. Captain Tomlinson, who served six months on the Mexican border, was valuation engineer for the Chicago & Western Indiana R.R. He reënlisted at the outbreak of the war, acting first as camp adjutant to the constructing quartermaster, Camp Grant, Illinois, before entering the Coast Artillery service.

O. C. Smith has been appointed manager of the recently reorganized Division of Steel and Machinery of the American International Shipbuilding Corporation at Hog Island, Penn. The division was previously known as the Division of Ship Design and Production. Other appointments in connection with the reorganization of the division are as follows: C. C. Thomas will continue as manager of the department of machinery; C. L. Harkrader has been appointed manager of the department of hull fabrication; H. W. Osgood will continue his duties as electrical engineer; D. E. Bigelow as estimator. All of the departments and sections are in charge of Mr. Smith.

Maj. James C. F. Shafer, 52nd Artillery, who previously was general manager of the Structural Concrete Co., Dayton, Ohio, has returned from France and received his discharge from the service. He has become vice-president of the Boldt Construction Co. of Cleveland, specializing in the construction of industrial and power plants.

W. A. Leland, formerly president of the Tennessee Eastern Electric Co., Johnson City, Tenn., has been appointed chief engineer and general manager, Charleston Engineering and Contracting Co., Charleston, S. C.

Maj. Edward D. Rich, Sanitary Corps, U. S. A., who was director of the School of Sanitary Engineering at Camp Greenleaf, Georgia, succeeding Maj. William C. Hoad, promoted to lieutenant colonel and ordered to the Surgeon General's office, has received his discharge from the service and has returned to his duties as state sanitary engineer of Michigan.

George W. Brown, who for 21 years has been engaged in the construction and operation of coaling plants for the Navy Department, has been relieved from duty at the Naval fuel depot, Tiburon, Colo., and placed in local charge of coal storage for the department at Hampton Roads, with headquarters at Norfolk, Va.

I. W. McConnell has resigned from the Division of Ship Design and Production, American International Shipbuilding Corporation, Hog Island, Penn.

Capt. W. J. Carrel, Engineers, U. S. A., who was attached to the training school in highway engineering at Camp A. A. Humphreys for the instruction of replacement troops for the expeditionary forces, has received his discharge from the service and resumed his duties on the faculty of the College of Engineering, University of Kentucky, in charge of courses in structural engineering.

Charles L. Spaulding, resident engineer, electric zone, New York Central R.R., with headquarters at New York City, has been appointed secretary and engineer to the Yonkers, N. Y., Water-Front Commission. In 1914 he became resident engineer in charge of construction work on four-tracking and grade-crossing elimination and new station buildings in the electric zone of the New York Central from the Grand Central Terminal to Harmon. He has also been engaged in the preparation of plans for the West Side improvement project of New York City.

H. G. Balcom has resigned from the Division of Ship Design and Production, American International Shipbuilding Corporation, Hog Island, Penn.

Capt. H. E. Babbitt, Engineers, U. S. A., who was engaged in work in the advance section in France, has returned to the United States and received his discharge from the service. He has resumed his work as associate in sanitary engineering, College of Engineering, University of Illinois.

James G. Esch, for the past year general manager of H. Schmitt & Son, Inc., general contractors, Milwaukee, has become vice-president of the Boldt Construction Co., Cleveland.

Col. C. H. Crawford, U. S. A., formerly of the Purchase, Storage and Traffic Division, General Staff, has been elected director of the American Association of Engineers, succeeding T. M. Chapman, deceased. Colonel Crawford is now associated with the Baldwin Locomotive Works, Philadelphia.

J. A. L. Waddell, consulting engineer of New York and Kansas City, has been made a corresponding member of the Sociedad de Ingenieros de Peru.

Lester E. Armstrong, previously of Babcock & Wilcox, has become advisory engineer for the Powdered Coal Engineering & Equipment Co., Chicago.

Capt. Herbert T. Nowell, Engineers, U. S. A., who previously practiced as a consulting engineer in Montana and Wyoming, specializing in city planning and public works, has received his discharge from the service and is now at New Rochelle, N. Y.

G. L. Gillette has resigned from the Division of Ship Design and Production, American International Shipbuilding Corporation, Hog Island, Penn.

E. Earl Glass, road department, Los Angeles County, California, has resigned to become sales manager, Hydrometric Co., Los Angeles, in charge of the sale of Reliance irrigation meters.

John F. Nealis, Aëro Observation, U. S. A., formerly engaged in research work for the United States Steel Corporation, has received his discharge from the service and become associated

with the Powdered Coal Engineering & Equipment Co., Chicago, as advisory engineer.

OBITUARY

WILLIAM N. BANNARD, formerly special agent, Pennsylvania R.R., in the office of the general manager, at Philadelphia, died in Wilmington, Del., Jan. 31. He was born in 1848 and was graduated from the Massachusetts Institute of Technology in 1869, when he entered the service of the West Jersey R.R. as a rodman. In 1872 he was appointed resident engineer of the West Jersey line, and two years later was made assistant engineer, New York Division, Pennsylvania R.R. In 1883 he was appointed superintendent of the Camden & Atlantic R.R., and a year later of the Schuylkill division. After serving for a short time as superintendent of the Schuylkill division he was appointed superintendent of the Amboy division, and afterward became superintendent of the Altoona division. In 1895 he was appointed superintendent of the Maryland division, with headquarters at Wilmington, and served in this capacity for 15 years, until his appointment as special agent in the office of the general manager.

DR. BROWN AYRES, president of the University of Tennessee since 1904, died in Knoxville Jan. 28, at the age of 62. He received his early education and course in civil engineering at Washington and Lee University and was afterward graduated from Stevens Institute. He was professor of physics, College of Technology, from 1880 to 1904.

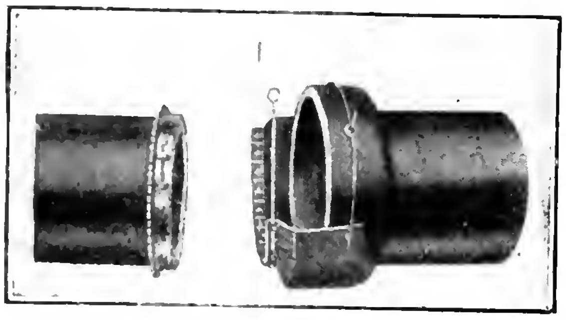
A. C. SCHILLING, attached to the Office of the United States Engineer, Mobile, Ala., died in that city Feb. 5. He was formerly connected with the engineering department of the Borough of the Bronx, New York City, and more recently had been assistant engineer and chief of sewers, United States War Department, in connection with installations at Camp Meade, Maryland.

FREDERICK DONALD HART died in Brooklyn, N. Y., Feb. 2, at the age of 84. He installed the first pumping engine for the Ridgewood pumping station of the old Brooklyn water-supply service. He also supervised the erection of the pumping engines, then said to be the largest of their kind, for Woodruff & Beach Iron Works, Hartford, Conn., installed in the Atlantic Ave., Brooklyn, pumping station in 1858. He remained in the service of the old City of Brooklyn as supervising engineer of the water-works until 1878, when he became associated with John W. Masury & Sons. He retired from active life in 1898.

Gasket and Form for Cementing Joints in Tile Pipe

A gasket and form has been designed by a New England contractor to simplify the making of waterproof cement joints in tile pipe sewers. It makes possible the maintenance of proper alignment of the invert while the pipe is being laid, and also the laying of the pipe in water.

The gasket consists of a sheet-iron flange, the inner edge of which is turned over to fit on the spigot end of the pipe, while the outer ring is notched to fit into the hub of the pipe into which it is to be placed. The outside diameter



GASKET AND FORM IN PLACE

of the gasket is the same as that of the inner diameter of the hub, and is held tight on the pipe by means of a small stove bolt through two lugs. The sheet-iron form is made to fit closely the outside of the hub as well as the pipe. It is placed on the lower half of the hub and is wired in place.

When pipe is laid the spigot with the gasket on it is placed in the hub in the usual manner and forced into place. No attempt is made to center the pipes, as the gasket does this automatically. The pipes are then tested for line and grade, and the trench is back-filled to a depth of one-half the diameter of the pipe. When this is done there can be no disturbance of the joints after they are made. After a convenient number of pipes have been laid in this manner the joints are poured with a thick grout from one side of the form. The upper half of the joint is then plastered with cement mortar in the usual manner.

With this device sewers have been laid in trenches containing water and with water running through the pipe to a depth of one-half the diameter of the pipe, thus saving the expense of pumping or the use of subdrains.

The device is made by L. A. Weston, Adams, Mass.

Foreign Trade Council Will Hold Convention in April

A formal call for the sixth National Foreign Trade Convention to be held in the Congress Hotel, Chicago, Apr. 24-26, 1919, was made by the president of the council. The urgency of the foreign-trade situation will be the theme of the convention.

"The abrupt termination of the war in Europe," says the chairman, "has brought the United States suddenly face to face with questions of grave concern to American foreign trade and industry."

BUSINESS NOTES

The Alexander Millburn Co., 1420 West Baltimore St., Baltimore, Md., announces that it has opened a branch office at 998 Monadnock Building, San Francisco, Cal., under the management of E. F. Walter.

Capt. Edward E. Ashley, Jr., formerly mechanical and electrical engineer for Starrett & Van Vleck, architects, New York City, has resigned his commission in the air service of the Army to accept an appointment as sales engineer of the Mercury Manufacturing Co., Chicago, Ill. The Mercury company manufactures electrically driven tractors for use in connection with industrial haulage systems.

Wharton Clay, director of the Military Training Camps' Association, has become associated with the Expanded Metal Manufacturers' Association as commissioner, and is located in the Cleveland office. Mr. Clay left the United States Gypsum Co. to take up association work when the association named above was founded.

The Portland Cement Association announces the appointment of H. G. Meigs as district manager of its Milwaukee office, First National Bank Building, Milwaukee, Wis.

TRADE PUBLICATIONS

The A. S. Aloe Co., of St. Louis, Mo., has isued a supplementary catalogue describing and illustrating engineering, drawing and drafting supplies which the company carries in stock.

The Wallace & Tiernan Co., 349 Broadway, New York City, has issued a 65-p., 8½ x 11-in., paper-bound book entitled "Chlorine Control Apparatus for Water and Sewage Purification." Besides being a treatise on the chlorination of water, its history and development, it contains a large amount of data and charts for use in the installation and operation of the apparatus manufactured by the company. It is illustrated with a large number of half tones showing the various equipment at work, as well as installations throughout the country. A summary of types and characteristics of the company's chlorinators is given.

The Blaw-Knox Co., Pittsburgh, Penn., has issued a pamphlet describing its automatic single-line clamshell bucket. The pamphlet illustrates the bucket in several operating positions, and gives other information regarding the machine.

Psychological Test for College Entrance

ONE definite effect of war experience on education is seen in the recent announcement that Columbia College will abandon the old system of entrance requirements and in September substitute psychological tests. These tests are patterned after those used in connection with the admission to the Students' Army Training Corps, but will be designed definitely to test the applicant's fitness for continuing academic work. As Dean Hawkes aptly expresses it, "We expect these tests to show us whether it will be worth our while to try to educate the student, and whether it will be worth his while to have us try." One of the best results of the new experiment, it may confidently be predicted, will be the more intelligent selection of students—for the system must by its very nature introduce more of the element of judicious choice, which is to be based not alone on the new psychological test, but also upon the high-school and general previous record of the student. In this way, the highly reprehensible practice of accepting men who cram up a few weeks before college entrance examinations, and then disgorge upon examination day, will be effectually abolished. It is to be expected that engineering colleges all over the country will follow in the adoption of tests of the new type, in order to determine those qualities of general intelligence and maturity of mind which in the last analysis make a given student's career in college valuable, both to himself and for the future of his profession.

Monolithic Brick Pavements Justified

CONCLUSIONS drawn from the investigation of the construction of the ramps of the Pennsylvania Station in New York City favor the use of rigid brick construction. Considerable interest centers around these ramps, the replacement of small sections of which is described on p. 378. This is due to the fact that they were among the earliest instances of rigid construction and also because they were a bone of contention between those who held to the old theory that vitrified brick must be laid upon a sand cushion, and those who favored the rigid system of construction known as the monolithic. The excellent service which these ramp surfaces have given is all the more striking because the brick were only slightly more than half the standard depth for paving block, which is 4 in. Furthermore, they had worn more than halfway through and were still in an unshattered condition, which certainly discredits the theory that impact has a pulverizing effect upon rigid brick surfaces, and supports the contention of those who advocate the use of much thinner brick in monolithic and semi-monolithic construction. In the reconstruction it has been necessary to use a deeper cement-sand bed than is usually recommended, to bring the pavement up to the new street grade. This would have been dangerous on the old sand-cushion type of construction, and the action of these surfaces with mortar bed will be watched with interest.

Work of National Society Secretaries

PROTEST has been made against a letter signed "M. Am. Soc. C. E.," printed in *Engineering News-Record* of Jan. 23, 1919, p. 201, wherein the author criticises the secretaries of our national engineering societies and foundations, declaring, among other things, that their sole occupation is to write useless reports and letters, and that they get two to three months' vacation a year. The sweeping scope of the criticisms is their own condemnation. Manifestly, it is absurd to characterize the work of the societies as useless, even though one does not agree with policies, while the statement that the secretaries get from two to three months' vacation each year does not accord with the facts. The thoughtful reader, conversant with the work of the societies, will realize that the concluding paragraph of the letter was perhaps written in a Pickwickian sense. We regret that, through an error in the editorial office, the offending paragraph was left in the letter.

Public Works or Public Charity

SINCE the signing of the armistice this journal has persistently urged the quick resumption of public works on a large scale, holding that it was the duty of the community to "take up the slack." In fact, even while the war was in progress, we persistently urged the planning of public works, holding construction in abeyance until hostilities should cease. Since the armistice came, the public-works propaganda has received considerable impetus. Much literature has been produced, but nowhere have we seen the case of public works versus public charity presented so clearly as in a pamphlet by Prof. Harold G. Moulton, of the University of Chicago, published by the Union League Club of Chicago. He puts the case in his conclusion in these expressive words:

"We know as a matter of course that we cannot permit either our returning soldiers or war workers to starve; we know that the least we can do, if jobs

are not available for all, is to open our charitable purses and extend them such indirect alms as we may. We have the choice, therefore, of two methods of meeting the situation: (1) By providing employment on public works of enduring value; (2) by supporting by public charity an army of unemployed in nonproductive idleness. The former is the way that will make for satisfied, self-reliant American citizenship; the latter is but a palliative—it prevents starvation, but it does not avoid ingratitude and bitterness of spirit, nor make for orderly social and economic life. The former is the socially efficient way, the way that conserves human resources and increases the productive capacity of the nation; the latter is the socially wasteful and inefficient way—that makes for the degradation of the individual and the depletion of national productive power.

"The latter is the way of the old era of ill adjusted and unregulated industrial life; the former is the way of a new era of economic and social efficiency. Which way shall we make the AMERICAN way?"

Universities Should Act to Help the Engineering Profession

THE protest of Dean Richards, of the University of Illinois, against the low pay of engineers in railway service, printed on p. 368 of this issue, is a protest from the right source. Such protests ought to be forwarded from dozens of the universities. There has been in the past a regrettable tendency on the part of engineering school authorities to close their eyes to the evidence that all was not well with the engineering profession. There has been ample publicity of statements from the engineering schools as to the great need for engineers and the great future of the engineering profession as a factor in the world's activities; but how seldom has there been outspoken public utterance to impress upon the public its great loss from failure to appreciate properly and reward properly the engineer's service!

The heads of our engineering schools are but human, and it has been quite natural for them to force into the limelight those of their graduates who have achieved phenomenal business success and quietly ignore the men, in many cases of equal ability, who, through force of circumstances, and—to put it frankly—the oversupply of engineers in particular fields, have been forced to continue in routine work at meager compensation. The heads of our great engineering schools and universities, however, have a large influence on public opinion. Such protests as that which Dr. Richards has so well voiced might well be heard from every school in the United States which teaches railway engineering. Such protests are called for not merely in justice to their own graduates and to the men they are preparing for service, but on the ground of public welfare. No one doubts the truth of Mr. McAdoo's recent declaration that national prosperity depends upon the efficiency of the country's transportation system. That efficiency is largely determined by the quality of the men placed in charge of the railways and their expert knowledge of the business. Unless railway engineers can receive adequate compensation, the engineering schools may as well abandon their courses in railway engineering.

Improving the Efficiency of Ship Fabrication

SHIPBUILDERS have been very slow to accept the idea of ship fabrication. Many of them are indifferent to the subject, some even to the degree of denying it a hearing in their own thoughts. With the completion of the two great inland fabricating shops built at the initiative of the Emergency Fleet Corporation, the fabricated-ship system takes on a new aspect. The layout of these shops, described in our issue of Feb. 13, 1919, p. 332, was not hampered by any external conditions, and had the benefit of thorough experience in all classes of steel fabrication. Shipyard shops lack similar advantages, and their comparative working results are likely to reflect this fact. They will find these new shops redoubtable competitors.

A recent English word on the prospective future of fabricated ship construction compels attention. Describing the "N" or national fabricated steel ships being built in England, *Engineering* of Jan. 17, 1919, said:

"The fabricated ship is a vessel of almost mathematical precision, which may in subsequent years set a distinct shipbuilding precedent, even among private owners. . . . No estimate of the cost of a fabricated vessel is available, but whether it be higher or lower than the cost of a vessel built in the ordinary way is no comparative criterion of value. Organization and facility of resource are the only weapons with which to combat the abnormal costs due to the war, and in consequence with the lapse of time the fabricated vessel is bound to prove a cheaper vessel than what might be termed a 'single-effort' ship."

For a year past, experiences in America have pointed substantially to this conclusion, available to all concerned with the shipbuilding industry; yet many yard men may regard the above expressed views as a weighty confirmation of what we ourselves had learned.

With shops now available for shipwork that are larger and more skilfully laid out than any shipyard shops, and, furthermore, are free from all the local limitations of the yard, the question of economy in the steel-fabrication part of shipbuilding will depend solely on the organizational skill with which the relations between shop and yard are handled. Given a satisfactory solution of this problem of organization, it may be said at once that on the score of economy the outside-fabrication system of shipbuilding will succeed in holding its own, since design and templet processes and the task of erection are easily adjusted to the system.

However, any new system, in order to become a working success, must be handled with sympathy and even a certain degree of enthusiasm. It is hardly open to doubt that the concerted hostility of all shipyard men would kill off the fabrication system temporarily, in spite of the most convincing demonstration of superiority. On the other hand, since the support and cultivation of any system tending to promote economy and efficiency is greatly in the national interest, it is to be hoped that the operation of the new shops will be directed with unusually careful attention to efficiency and schedule sequence, and that the facts as to results obtained may be made public as soon as possible. By this course the real possibilities of outside fabrication should be fully developed, and their application for the benefit of our shipbuilding industry made certain.

Garbage During the War and After

THE war wrought sweeping and, it may be, lasting changes in garbage disposal. It lessened the volume and grease content of garbage and led many cities to utilize vast quantities of fats and fertilizer base which had been going to the dumps or the furnaces. It is hardly to be expected that the household economies which resulted in decreased volume and richness of garbage will be fully maintained now that the war-saving spur is over, but in the interests of family, community and national thrift it is to be hoped that not all this gain will be lost. Certainly, for some years to come engineers, contractors and municipal officials having to do with garbage disposal cannot safely ignore these reductions in the quantity and richness of municipal garbage

How extensive have been the changes from nonutilization to utilization methods, the great further possibilities in this respect, and the main trends in garbage collection yields during the past two years, are shown by data and analysis in a contribution by F. C. Bamman, based on United States Food Administration investigations, which appears elsewhere in this issue.

The outstanding fact in the article is that during the year 1918 alone, 40 cities changed from dumping or burning their garbage to feeding it to hogs. That only three cities changed to reduction was chiefly due to war inhibitions on using capital, labor and materials for building reduction works. But now that the possibilities of hog feeding, with its relatively small plant and capital equipment, and the speed with which it can be got into use, have been shown, further rapid extension of this method of disposal may be expected.

Experience shows that garbage feeding is practicable for large cities. Some of the cities that changed from waste to feeding in 1918 have populations of more than 100,000. Moreover, already in 1919 Baltimore has let a five-year contract under which the garbage of that large city will be fed to hogs, as set forth at length in *Engineering News-Record* of Feb. 6, 1919, p. 287, and St. Louis has made terms for disposal by feeding while drafting specifications on which to invite bids for a longer contract. It should be noted that this change at St. Louis means the closing of a garbage-reduction plant.

Demands for glycerine and fats during the war stimulated garbage reduction wherever plants for that purpose were available. A world shortage of fats still exists, but recently the price of grease has fallen heavily, apparently due to after-war conditions which it is hoped will be but temporary. There is still need for fertilizer tankage which, like grease, is a product of garbage reduction. It is to be expected that ultimately both grease and tankage will sell at considerably less than war prices. This must be taken into account in projecting new garbage-reduction plants, as must also the present high prices of material and labor entering into their construction.

Until the various uncertainties now attending garbage reduction are removed by time and experience, conservatism in entering on new projects will be the part of wisdom. This does not mean that a pound of garbage need be wasted. Hog feeding is a ready means of utilization which should receive consideration wherever reduction—in existing or new plants—is for the time being impossible or of doubtful expediency.

The municipal field for garbage utilization by either reduction or feeding is still large. Mr. Bamman's conclusion is that the garbage now wasted would yield 30,000,000 lb. of grease and 60,000 tons of fertilizer tankage, with a remainder sufficient to produce 40,000,000 lb. of pork yearly. The world needs this grease, fertilizer and pork. Our cities, engineers and contractors should join hands for their production.

At such a juncture those unfamiliar with political and other local conditions in New York may well be surprised to hear that the garbage of some 5,000,000 people is to be dumped at sea temporarily while plans are being made and effected to burn it in refuse destructors scattered over the city. No evidence has been brought forward to show that the reported decision to destroy vast potential quantities of grease and fertilizer is based on careful engineering studies. The subject is one to which the engineers and engineering societies of Greater New York might well direct immediate attention.

A Federal Department of Public Works

IN TWO committee hearings recently members of Congress have discussed with witnesses proposals to establish a Federal Department of Public Works. One of the proposals was, it is true, for an emergency board, but the principle of a single engineering construction organization for the National Government was involved.

To the surprise of the civilians who appeared before the committees, the attitude of the senators was a sympathetic one. The war lesson as to the value of coöperation has had a telling effect, and the absurdity of scattering the Government's engineering and construction work through five administrative departments stands out stronger now than in the days of antagonistic individualism. A government which demanded of each industry that it mobilize in a single trade association or war-service committee does not find it so difficult now to see prospective benefits from combining under one head all its own functions of a similar character.

We do not believe that there is a member of Congress who would undertake to defend the placing at one time of public-building work under the Treasury, river and harbor work under the War Department, the Geological Survey under the Interior, and the Coast and Geodetic Survey under the Department of Commerce. No logic can defend the existing situation. Administrative exigencies or influences, which long since have disappeared, made for a now indefensible distribution.

But that which exists, no matter how absurd and illogical it may be, will always have defenders. Consequently, it will be necessary for those—the engineers of the country—who realize the absurdity of the present scattered scheme, to press home repeatedly and with emphasis the advantages of coördinating all of the Government's construction and engineering work. What are the advantages?

Under centralization, there would be elimination of duplication, especially in supervising the widely scattered work of the Government. There would be standardization of specifications and of materials. The large scope and volume of work would permit of the employ-

ment of a goodly number of broad-gaged engineers at the top, whose experience and counsel would make for the broader planning and execution of work. In private engineering enterprises it has been demonstrated that a high-salaried engineering organization is a *sine qua non* of economy. Then, too, come all the advantages of close alliance between men engaged in the same class of enterprise—the interchange of thought between experts—while the size of the organization would permit of a degree of functionalization not possible when the same amount of work is split up among ten or more bureaus.

These are obvious advantages; advantages such as are reaped in any consolidation, whether in industry or in government bodies; advantages that have been aimed at in several states in consolidating their engineering and construction bureaus into a state department of public works.

But there is another advantage which in the National Government weighs heavily for a Department of Public Works. It so happens that the great Congressional pork barrels are the rivers and harbors and the public buildings bills. These have become public scandals because no great administrative department in the President's cabinet was in a position to lay out a defensible scheme of public improvements that the President could back as a policy and on which he could solicit the support of the country. The execution of rivers and harbors work has been a side issue with the War Department, and its immediate execution placed in the hands of men whose habit is to obey without question, whose initiative is discouraged by the Army system, and who lack the business experience and point of view to assume responsibility for an economic program. Consequently, though executed under a body of notably highminded men, our river and harbor work has been—counting returns for our expenditure—one of the shames of the nation. A Secretary of Public Works and Engineering in the President's cabinet could secure for a sound policy that Presidential support which on occasion, by threatened veto, has forced river and harbor bills into some semblance of decency. Moreover, a sane policy would be a refuge for many a Congressman now forced into the pork scramble by real or assumed pressure from constituents and by the contagious example of his fellow legislators.

Were the ten or more engineering and construction activities of the Government thrown into one department, the aggregate expenditure, on the pre-war (1916-17) basis, would be nearly $100,000,000. This would be no mean department, for, on the basis of amount of appropriation, it would be exceeded only by the War and the Navy departments.

Reforms of this sort do not come easily. They do not come through the silent wishes of thinking citizens, nor even through the resolutions of engineering or other bodies. They come through the education of the people's Congressional representatives by the people themselves.

If you believe that there should be a national Department of Public Works, if your engineering society believes it, there is but one useful course of action—to tell it to your Senators and Representatives. And, in the telling, it might be wise to soften your strong views on the iniquity of pork-barrel methods.

How Not to Start a Canal Going

OFFICIAL explanations of last year's low traffic on the completed New York canal system, as abstracted on another page, do not increase public confidence in the Federal control of the system. Operating a modern canal is a new business in this country. Neither navigators nor shippers are used to it; the one is not at all persuaded either of its economy or its effectiveness, the other does not sufficiently realize that old mule-boat methods mean the added time and expense which defeat the purpose of the waterway. They both, in the advertising man's parlance, have to be "sold" on the canal "proposition." The State of New York has $155,000,000—much more if the old canal is capitalized—tied up in the Barge Canal, and it cannot get a fair return on this investment unless the canal is used. To get it used is the main duty of those who control it. Here is where the Railroad Administration failed.

The Federal authorities took the canal over as a going part of a successful transportation business—that is, the railroads adjacent to the canal—and expected it to show like returns on the investment. It did little to encourage canal traffic except to provide boats, which, contrary to prediction, were available far in excess of the freight offered. It permitted an erroneous impression of Federal monopoly of operation to remain abroad many months. Finally, it insisted on freight rates which paid a profit according to its own system of bookkeeping, the bookkeeping of a going concern. "Here is the canal; use it or leave it," was, in effect, its attitude.

No waterway today can be started on any such basis. The economy of canal transportation is at best debatable, and it will not be settled in this country until a fair experiment is carried through. An experiment will not be fair unless all the methods of starting any new business are tried. Such methods include liberal advertising and publicity, and small profits until trade is developed. To expect a waterway business automatically to spring full grown into successful financial competition with long-established railways is to kill it before it is well started.

There is a growing sentiment in favor of waterways in the United States, in spite of what appears to be good economic evidence against them. Strangulation of the one full-sized experiment will not kill off the growth of others. In justice to the whole transportation problem, on which the critical cost of living so depends, the New York canal system should have a fair chance to show what the modern inland waterway can do. It cannot have that so long as it is run entirely by railway men or is under divided control—or, worse yet, under an unprejudiced administration which considers it as a passive route ready for those who may want to use it. It must be administered by those who want to show that it is eventually to be successful. It first must be made known to the people who should use it, and then its use must be made attractive. If there is anything at all in the inland waterway idea, it is that the increased public first cost will be returned to the people in reduced final cost of the commodities which go over the waterway. Increasing that first cost a little, then, to make the proposition known, and to get it used, is only good business judgment.

Economic Balancing of Highway Excavation by a Semi-Graphic Method

Device Called "Trace Curve," Used in Designing Storm King Highway of New York State Highway Department, Is Particularly Useful to Supervising Engineers in Checking Earth Distribution

By Dudley P. Babcock
Assistant Engineer, New York State Highway Department, Albany, N. Y.

DETERMINATION of the economic distribution of excavated material in the location of the Storm King and other highways of the New York State Highway Department has been effected by a new method, utilizing what is called a "trace curve." The solution is partly graphic and partly analytical, and has for its underlying principle the assumption that for slight raising and lowering of cuts and fills the added and subtracted quantities are proportional to the surface areas multiplied by the change in elevation. The device is particularly applicable in new locations which are unhampered by existing improvements, and where the excavation quantities are large. By requiring his assistants to plot a trace curve of their grade design, the supervising engineer will find it easy to detect quickly any uneconomical balances and compute roughly, without recourse to the cross-sections, the probable saving which would result from any proposed change.

Selection of the grade and alignment of highways has ever been, and always will be, largely a matter of judgment developed by experience, rather than an exact mathematical science. This is evident because no formula can adequately represent the ground surface; also, the governing factors in determining grade and alignment are not only the economic haul and quantity of earth to be moved, but also involve the adjacent structures, trees, fences and roads, together with the maximum grades permissible in each direction, the drainage—and last, but not least, the æsthetic features, For example, wide shoulders, shallow ditches, fairly long grades with decided breaks, large vertical curves and a winding alignment will make a road attractive but not necessarily economical.

There are cases, however, where a road is to be built over rough country where no previous roads existed and where many of the factors mentioned above are either nonexistent or at least unimportant. After the maximum grade has been established on such roads, the principal factors affecting the design of the grade and alignment are reduced to two classes—the æsthetic and the economic. If the earthwork is comparatively heavy, which is often the case on roads of this type, a thorough study is warranted, to determine minimum hauls and excavation. The former may easily be determined by means of the mass diagram, but the latter, while seldom neglected entirely, does not receive the attention it deserves.

The trace curve may be defined as follows:

If upon the plan of a road in side-hill cut the traces formed by the intersection of the side slopes with the original surface were drawn, also the line of zero cut and fill; then if the zero cut-and-fill line were rectified and the above-mentioned traces were modified so as to bear the same relation to the rectified line that they bore to it before rectification, the result would be a trace curve. If the zero cut-and-fill line happened to be straight, originally, then the traces of the side slopes would be trace curves and no modification would be necessary.

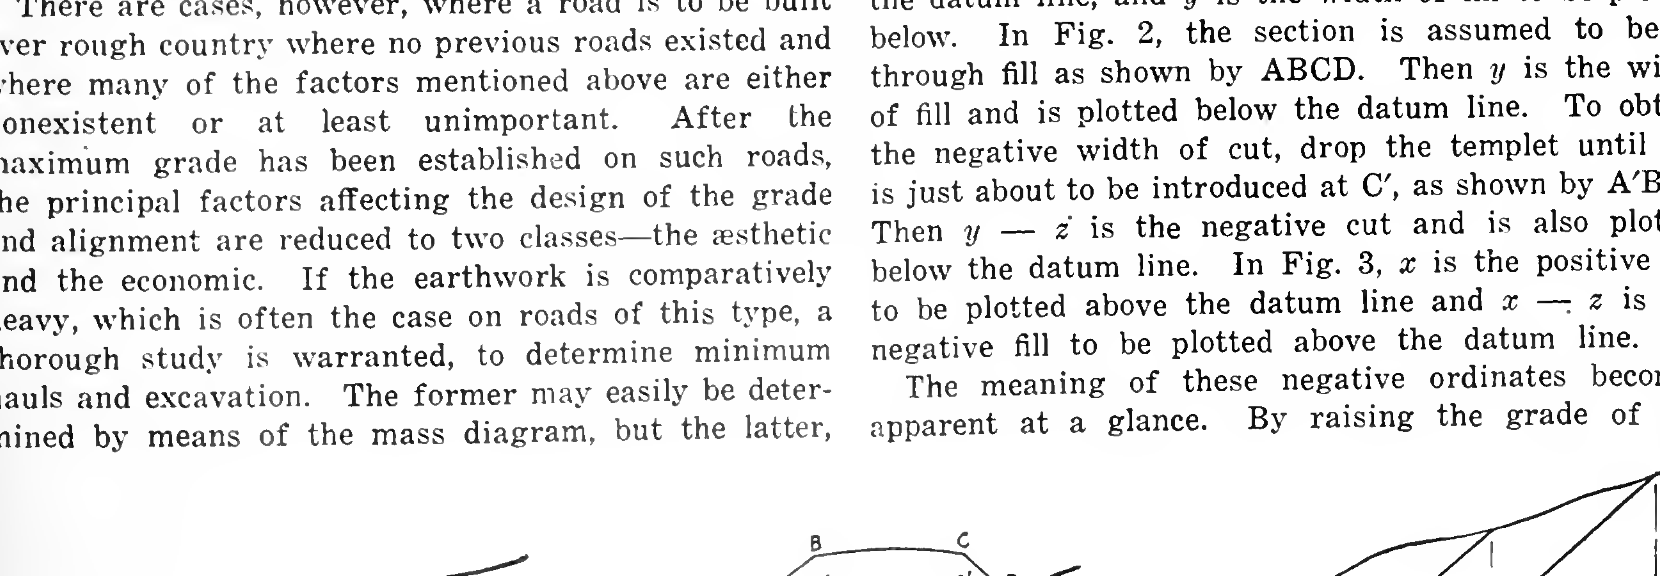
The trace curve is made by plotting center-line stations as abscissas and widths of cuts and fills of corresponding sections as ordinates. The cut widths are plotted above the datum line and the fills below, resulting in two curves—one normally above and the other normally below the datum line.

In the case of through cuts, the fill is assumed to be negative (i.e., plotted above the datum line) and equal in amount to the width of the cut minus the width which the cut would have if the grade were raised until the first iota of fill were introduced. In the case of through fills, the cut is assumed to be negative (i.e., plotted below the datum line) and equal in amount to the width of the fill minus the width which the fill would have if the grade were dropped until the first iota of cut were introduced. This may seem somewhat complicated, but, as a matter of fact, it is quite simple and takes but a moment to apply.

The following figures illustrate the matter:

In Fig. 1, x is the width of cut to be plotted above the datum line, and y is the width of fill to be plotted below. In Fig. 2, the section is assumed to be in through fill as shown by ABCD. Then y is the width of fill and is plotted below the datum line. To obtain the negative width of cut, drop the templet until cut is just about to be introduced at C′, as shown by A′B′C′. Then $y - z$ is the negative cut and is also plotted below the datum line. In Fig. 3, x is the positive cut to be plotted above the datum line and $x - z$ is the negative fill to be plotted above the datum line.

The meaning of these negative ordinates becomes apparent at a glance. By raising the grade of the



FIGS. 1, 2, 3. WIDTHS OF POSITIVE AND NEGATIVE CUTS AND FILLS

road shown in Fig. 1, the decrease in the value of x roughly equals the increase in the value of y, until the condition is reached as shown at A′B′C′, where the value of x is reduced to zero. Assuming, however, that the same relation continues to exist between x and y as the grade is raised further, the value of x for the position ABCD is negative and equal to $y - z$. In like manner, when the grade is dropped it may be shown that the negative value of the fill width designated by y will be $x - z$.

Meaning of the Trace Curve

Primarily, the object of the trace curve is to determine the highway profile requiring the minimum quantity of excavation. It does not take the place of the profile nor the usual method of balancing cuts and fills, but simply furnishes the criterion as to whether the particular arrangement of cuts and fills in question (assumed to be balanced) gives the minimum quantity of excavation possible under the circumstances. For example, assume two adjacent stretches of highway, A and B, each a few hundred feet long, which have been grouped together to form a balance. Let

b = balance ratio;
C = total cut;
F = total fill.

Then

$$\frac{C}{F} = b.$$

Now assume that the grade is raised a small amount over the section A and lowered a small amount over the section B, the latter change being so related to the former that the balance ratio b is preserved. Let

c_1 = cut eliminated by raising the grade in A;
c_2 = cut introduced by lowering grade in B;
n_1 = ratio of fill introduced to cut eliminated in A;
n_2 = ratio of fill eliminated to cut introduced in B.

So that

$$c_1n_1 = \text{fill introduced in A;}$$
$$c_2n_2 = \text{fill eliminated in B.}$$

Then

$$c_1 - c_2 = \text{net saving in cut;}$$
$$c_2n_2 - c_1n_1 = \text{net saving in fill.}$$

But if the balance ratio is preserved after as before the change

$$c_1 - c_2 = b(c_2n_2 - c_1n_1) \qquad (1)$$

Now let

$$k = n_2 - n_1$$

or

$$n_2 = k + n_1.$$

Substituting in (1)

$$\begin{aligned} c_1 - c_2 &= b(c_2k + c_2n_1 - c_1n_1) \\ &= bkc_2 - bn_1(c_1 - c_2) \\ (c_1 - c_2)(1 + bn_1) &= bkc_2. \end{aligned} \qquad (2)$$

From (2) we see that the saving in excavation is positive if k is positive, and it is negative (i.e., the change represents an increase in excavation) if k is negative. If k is positive then $(n_2 - n_1)$ is positive or n_2 is greater than n_1. Now, it may be easily shown that the values of n for small changes in grade are equal to the ratio of widths of fill to widths of cut. Thus, referring to Fig. 1, if the section is raised a small amount v, the increase in fill will be vy and the decrease in cut will be vx. Therefore,

$$n = \frac{vy}{vx} = \frac{y}{x}$$

i.e., n equals the ratio of width of fill to width of cut.

The method of using the trace curve should now be apparent.

Method of Applying Trace Curve

The road is first balanced roughly, using the profile and cross-sections in the usual way. The trace curve is then drawn, showing the widths of cut and fill plotted to any convenient scale vertically and the stations horizontally. The positive cuts are plotted above the x axis, the negative ones below and the fills vice versa, as described above.

Wherever the area included between the cut-and-fill lines drops below the x axis, the grade, if possible, should be lowered and then raised somewhere else where the reverse condition holds; for n for the grade being lowered is higher than n for the grade being raised, and $n_2 - n_1 = k$ is positive. Also, in general, wherever two adjacent stretches can be found where the values of n differ, the grade corresponding to the higher n should be lowered and the other raised to preserve the balance.

A few illustrations will serve to make the above more clear. First, assume perfectly level ground, transversely, and a profile as shown in Fig. 4. The road has been balanced between A and C. It will at once

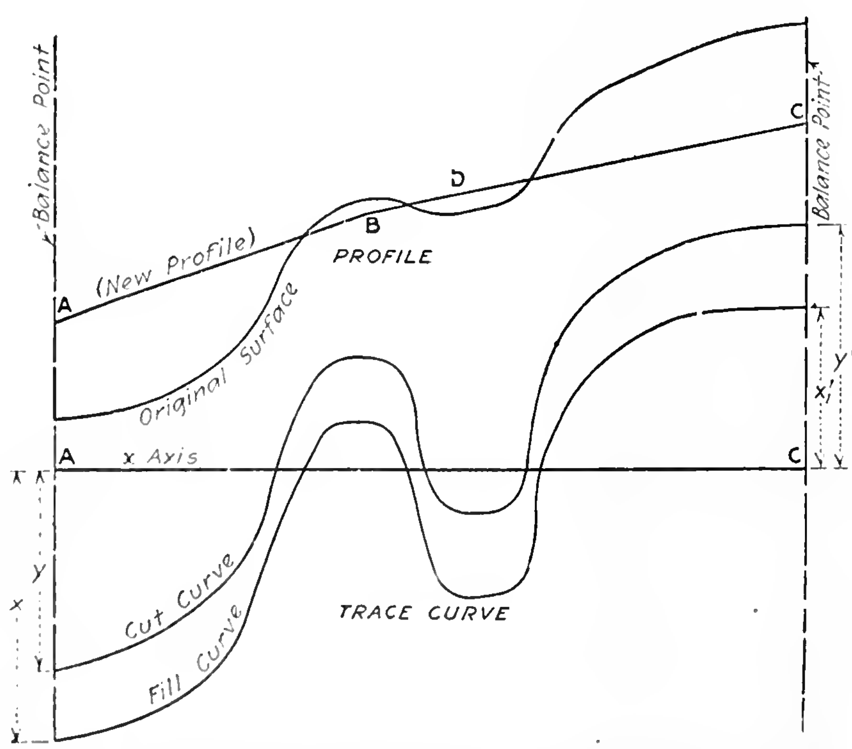


FIG. 4. FORM OF TRACE CURVE WHERE GROUND IS LEVEL TRANSVERSELY OF ROAD

be apparent from the profile that the grade as designed is uneconomical and should, if other conditions permit, be revised. If AB is already a maximum grade, it should be dropped bodily, thus eliminating a large amount of fill at A and introducing a smaller amount of cut at B. To restore the balance BC may now be raised, which will reduce the cut greatly at C, although introducing a small amount of fill at D.

Better yet, it may be possible to hold the B end of grade BC and raise the C end, thereby eliminating cut to even greater advantage. This is shown also

by the trace curve (Fig. 4). The uneconomical fill is shown at A by the fact that the area between the cut-and-fill line is below the x axis, and the uneconomical cut is likewise apparent at C because this area is here well above the x axis. In case the ground is level transversely (as assumed above), it is very evident that the trace curve is superfluous. Here the profile is all that is necessary for economical balance. If, however, the ground sloped transversely and with varying pitches in amount and direction between A and C, then the profile would be of little or no use for this purpose, and the trace curve alone would serve as the criterion for economical balance.

This last condition is shown in Fig. 5. Here the road is assumed to be in side-hill cut with the grade

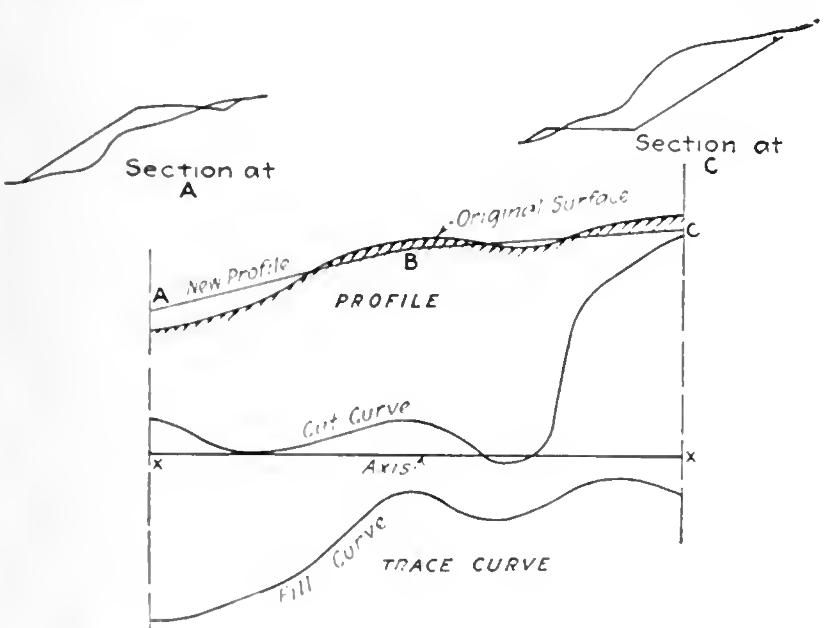

FIG. 5 FORM OF TRACE CURVE WHEN ROAD IS IN SIDE-HILL CUT OR FILL

profile following the center line very closely, but at A the fill side is very steep and the cut side almost level, whereas at C the reverse holds. An economical balance of the section AC requires the same changes of grade as in the first case—viz., the dropping of grade AB and the raising of grade BC. But, unlike the first case, the profile in no wise indicates the fact.

Fig. 6 shows a short section of the trace curve of an actual highway. It covers one balance, i.e., the cuts are in excess of the fills by the balance ratio assumed; in this case about 1½. A study of this trace curve will reveal the following characteristics:

1. Both the cut-and-fill curves follow the surface profile in a general way.

2. Through cuts occur when both the cut-and-fill trace curves lie *above* the x axis, as at A. Through fills occur when both curves lie *below* the x axis, as at B. When the x axis lies *between* the curves the section is partly in cut and partly in fill, as at C.

3. The distance between the curves at any point is a measure of the average transverse slope of the ground at the corresponding section. Thus, the transverse slope at D is much steeper than at A, B, or C.

4. When in through cut the distance between the cut curve and the x axis at any point is a measure of the total width of the corresponding cross-section, for example, rA. When in through fill the distance between the fill curve and the x axis is the measure of the total width of the corresponding cross-section, for example, uB. When the section is partly in cut and partly in fill, the measure of the width of section is the distance between the cut-and-fill curves, for example, xy.

5. The area included between the x axis and that portion of the cut curve lying *above* the x axis is the measure of the amount of cut obtained by lowering the grade uniformly a small unit amount. Thus, if this area $= M$ and the grade is lowered a small amount n (less than 1 ft.), then the amount of cut obtained by such lowering $= Mn$. Similarly, the amount of fill introduced by raising the grade uniformly a small amount q is measured by Pq where $P =$ the area between the x axis and the fill curve lying *below* the x axis.
